The Crude Oil Transportation Systems Final Environmental Statement is divided into four volumes plus a separate Summary:

Volume 1 contains a description of each of the four Title V proposals and a description and analysis of the proposed Northern Tier Pipeline Company system.

Volume 2 contains a description and analysis of systems proposed by Northwest Energy Company, Kitimat Pipe Line Ltd., and Trans Mountain Oil Pipe Line Corporation. A summary of the four Title V proposals is presented.

**Volume 3 contains alternatives to each of the four systems and public comment on the draft Environmental Statement. Environmental statement team responses are included. Glossary and References.**

Volume 4 contains maps relating to each of the four proposals.

# ALTERNATIVES TO TITLE V PROPOSALS

## 9.1 Introduction

The previous chapters considered the environmental effects of constructing and operating crude oil transportation systems. This chapter considers the environmental effects of not selecting a proposed system, of delaying selection of a system, and of accomplishing the purposes of the proposed action by other alternatives.

While the specific environmental impacts of constructing, operating, or abandoning a crude oil transportation system depend upon the environmental setting, many are constant and common to each system. For example, while similar noise levels would be created in trenching for a pipeline in similar soils, the impacts of those noise levels would vary depending upon the location of the trench. While vegetation would be destroyed in the construction of onshore storage facilities, the type of vegetation may vary. While wildlife would generally avoid construction sites, the specific species may vary.

Rather than repeat those common elements, this chapter sets forth those impacts unique to the specific alternative or highlights those impacts considered to be the most important. See chapters 3, 5, and 8 for a detailed analysis of the environmental impacts common to each proposal.

## 9.2 No Action

The no action alternative assumes that the decision would be made not to select any of the four proposed crude oil transportation systems, thereby precluding implementation of the projects as proposed by the four applicants under Title V of the Public Utility Regulatory Policies Act of 1978.

No action on the proposals would avoid both adverse and beneficial impacts. Adverse environmental impacts as discussed in chapters 3, 5 and 8 would not occur. For example, adverse impacts of construction of access roads, temporary degradation of stream crossings, and disruption of farming operations would not occur. Increased oil-spill risks from tanker casualties in the Strait of Juan de Fuca, Douglas Channel, and Lynn Canal would be avoided. Oil pipeline spills would be eliminated, the risks of fire and explosion would be eliminated.

Beneficial impacts to regions located along the proposed pipeline corridors also would not occur. Employment and tax benefits generated by the construction and operation of the proposed pipeline projects would not materialize.

If one of the pipelines is not constructed and a crude oil shortage develops in the northern tier states, northern tier refineries would need to find alternative ways of obtaining crude oil, cut back, or stop production. A cut-back would lead to an increase in unemployment and loss of revenue. Alternative methods of transporting crude oil to northern tier refineries such as continuing tanker transport through the Panama Canal, may have higher transportation costs leading to higher product costs.

Without one of the proposals, the excess to west coast refinery needs would continue unless production at Prudhoe Bay were curtailed to equal west coast demand. This could result in adverse economic impacts in Alaska. If Prudhoe Bay production continues at full capacity, there may be increased environmental impacts and attendant oil spill risks in transporting Alaskan crude from Valdez through the Gulf of Mexico to the southern and eastern states.

## 9.3 Delayed Action

The delayed action alternative assumes that the selection is neither approved nor denied and that no new port facilities or crude oil pipeline as proposed by the applicants would be constructed pending permit approval or disapproval.

Many of the same impacts would result from the delayed action as from the no action alternative. Therefore the effects of a delayed action could be similar to that of no action for the length of the delay. The delayed decision of permit approval or denial for the proposals may result in no other alternative system being initiated pending the decision. Conversely, the delayed decision could accelerate the consideration of other alternatives, which, if implemented, could eliminate the need for the proposals.

Delaying action on selecting any of the applicants' proposals would allow the Department of the Interior to gather additional environmental data for further analysis. This would permit a more thorough impact analysis of the four proposals.

## 9.4 Alternatives of Northern Tier Pipeline Proposal

### PORT AND ONSHORE FACILITIES ALTERNATIVES

The following ports represent alternatives to the Port Angeles port proposed by NTPC. The five alternative ports being considered represent alternatives for a transshipment port which, in conjunction with a west coast to midwest pipeline, could serve the crude oil demand in northern tier states (figures 9.4-1 and 9.4-2).

Cherry Point and Burrows Bay were evaluated on the basis of similar tanker berthing, onshore storage facilities, and crude oil volume as proposed for the Port Angeles port. The ports of Freshwater Bay and Low Point were evaluated using single point mooring (SPM) sites rather than fixed tanker berth. Also, a hypothetical pipeline route to a junction with the proposed NTPC pipeline route was assumed. For each of the port alternatives a description is presented followed by a summarized impact analysis by environmental elements.

# Ports and Around Puget Sound Alternative

# CHERRY POINT

## Description

Cherry Point is located at the southern end of Georgia Strait, approximately 10 miles from the Canadian border and 140 miles from the Pacific Ocean (figure 9.4-3). Two oil refineries, Atlantic Richfield Oil Company (ARCO) and Mobil Oil Company, have a combined refining capacity of 175,000 barrels per day. The firms have berthing facilities located in 65-foot and 42-foot water depths. Cherry Point is currently served by tankers off-loading into a shoreside pipeline to the storage facility.

Use of the existing Cherry Point facility as a transshipment port to off-load foreign and Alaskan crude oil would require construction of two additional berths, onshore storage facilities, and a pipeline to near Arlington, Washington. A new 42-inch, 66-mile-long, pipeline would be needed from the storage facilities to Arlington. From Cherry Point it would go eastward to an area north of Bellingham, then parallel the Trans Mountain Pipeline right-of-way to an area near Burlington where the Trans Mountain Pipeline turns westward to the Anacortes refineries. New pipeline construction and new right-of-way would be required for 66 miles south to Arlington, where it would join the proposed pipeline route.

Construction of this alternative port is prohibited by amendment to the Marine Mammal Protection Act (P.L. 95-136).

## Climate and Air Quality

No impacts on climate are anticipated.

Dispersion conditions for air pollutants in the Cherry Point area are generally good. Winds are primarily from southerly to southeasterly directions; northerly winds are common in winter. The average wind speed is about 7 miles per hour. Neutral and unstable atmospheric stability occurs about 53 and 18 percent of the time, respectively. Therefore, good atmospheric mixing takes place most of the time. Stable conditions, indicating less favorable dispersion, occur about 29 percent of the time.

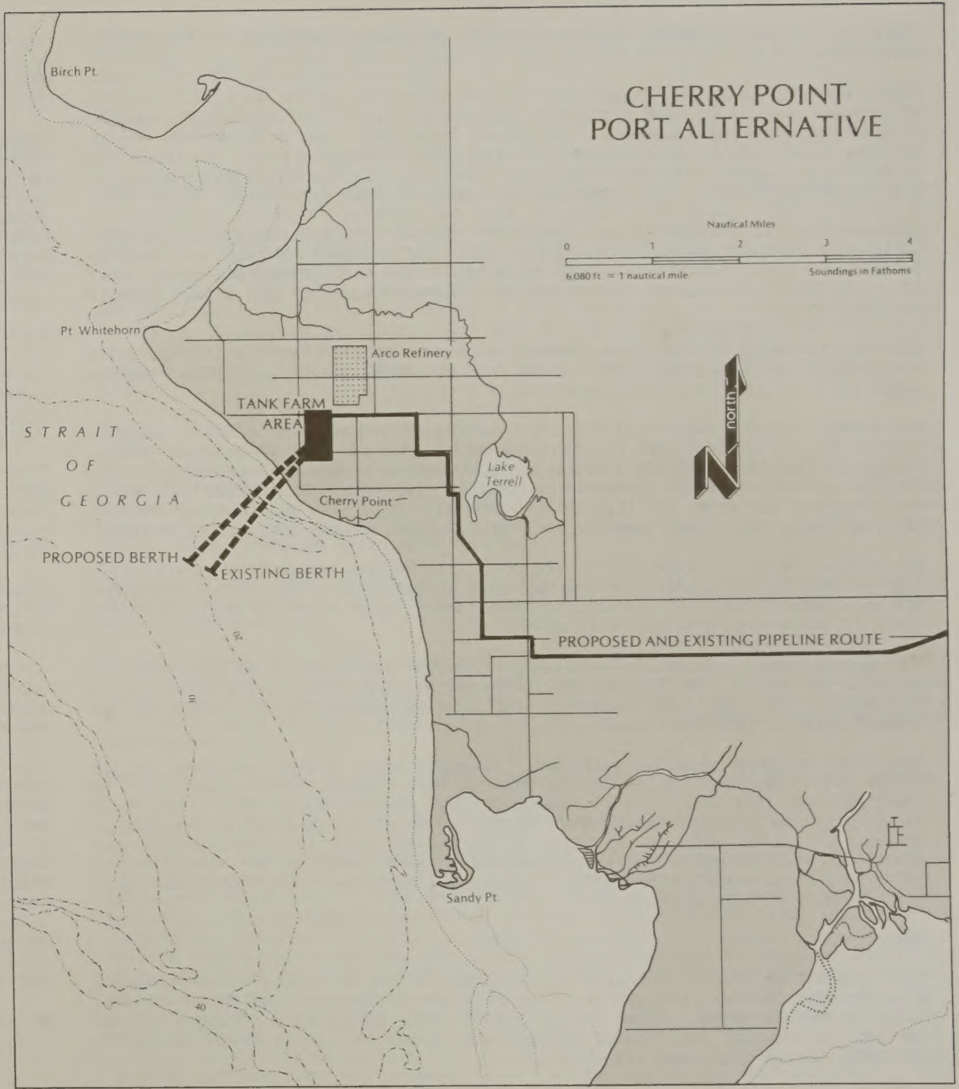

Figure 9.4-3

There is little available data on vertical temperature profiles or temperature inversions.

Major existing sources of air pollution consist of two refineries, an aluminum plant, and a paper mill which emit significant amounts of sulfur dioxide, nitrogen oxides, particulates, and hydrocarbons. Monitoring data exist for particulates, sulfur dioxide, ozone, and carbon monoxide. Air quality is generallly good. No violations of ambient air quality standards have been observed, with the exception of occasionally exceeding the state 1-hour standard for sulfur dioxide (SAI 1978).

Modeling for the proposed project pollution sources (SAI 1978) indicate that NTPC would need to limit the sulfur content of fuel used by tankers in port to about 1.0 percent in order to meet the 24-hour class II incremental standard for sulfur dioxide. The 3-hour average and annual average increments would be well within class II standards.

Modeling for existing emissions combined with project emissions resulted in 1,968 ug/m3, 1,389 ug/m3, and 635 ug/m3 for the maximum 1-hour, 3-hour, and 24-hour average sulfur dioxide concentrations, respectively.

The highest annual average sulfur dioxide concentration was 344.0 ug/m3 for existing sources only, and 345.0 ug/m3 for the combined existing and proposed sources. Tanker emissions therefore result in a negligible contribution to the concentrations. Since on-site monitoring showed lower concentrations than those calculated, the models overestimated pollution levels. It is unlikely, therefore, that the use of this alternate port site would cause any violation of the ambient air quality standard.

The maximum 24-hour average particulate concentration from the project is 4.4 ug/m3. This is well within the 24-hour average class II increment of 37 ug/m3. The annual average concentration is estimated as less than 1 ug/m3 which is well within the class II incremental standard of 19 ug/m3.

The highest annual average concentration of nitrogen oxides from this alternate port alone is 1.0 ug/m3. The highest annual concentration from existing sources only is 8.0 ug/m3. Thus the contribution of the proposed sources to the annual average concentration is relatively small.

There was no ozone modeling performed. However, since project emissions at the Cherry Point site would be similar to those at Port Angeles, ozone impacts would be about the same (SAI 1978). Little change in ozone concentrations would occur in the vicinity of the berthing facilities. Ozone concentrations downwind of the onshore storage facilities might be increased by 10 percent above background levels when conditions were favorable for ozone formation. Ozone levels in the area presently meet the federal standard (SAI 1978). It is not likely that the project would cause any violation of federal standards.

## Noise

Noise impacts would occur during the construction of the berthing facilities causing a noticeable increase in daytime noise at a few residences near the shoreline. Noise levels would be highest during pile driving operations. Onshore storage facility construction would cause daytime noise levels between 65 and 69 dBA at the residence nearest the construction site.

During the operation phase the primary noise source would be electric motors at the pump station. Noise levels would be about 58 dBA at 400 feet. Nearby residences might notice an increase of about 2 dBA above background noise levels.

## Topography and Geology

This port and 66-mile route segment alternative is characterized by relatively gentle terrain with a short stretch of modertely steep foothills at Lookout Mountain (Cherry Point route pipeline mile 20). Although the proposed route from Port Angeles to Arlington would require a 20+ mile submarine crossing, resulting in somewhat more acreage disturbed than on dry land, the overall terrain at both port sites and along their pipeline routes would be similar. Topographic impacts, consisting of minor landform changes and drainage alterations, would be essentially the same.

Geologic material encountered at Cherry Point and along the pipeline route to Arlington would be similar to that encountered at Port Angeles and along the proposed pipeline route to Arlington. It consists of Quaternary glacial and alluvial material with some outcrops of Tertiary sedimentary rock. Impacts would be similar consisting primarily of excavation of geologic material and excavation-induced changes in the physical characteristics of the material.

However, as the proposed route would involve a marine crossing and four steep coastal bluffs, substantially more geologic material would be excavated. Resultant impacts would be greater than along the Cherry Point-Arlington alternate.

### Geologic Hazards

Geologic hazards that could be encountered between Cherry Point and Arlington would be much the same as those encountered between Port Angeles and Arlington and would consist of seismicity and slope instability.

Cherry Point and the pipeline route to Arlington, like Port Angeles and the proposed pipeline route, is located in an area of moderate to high seismic activity, corresponding to a seismic risk zone 3 (maximum earthquake damage expected). Howver, no known active or potentially active faults or large magnitude earthquakes have been identified within 25 miles of the port site or pipeline route. While Port Angeles and the proposed pipeline have not experienced large magnitude earthquakes, the presence of an inferred, potentially active fault within 2 miles of the site and the level of seismic activity would indicate potential impacts from an earthquake would be greater than for the Cherry Point alternate.

Potential slope instability problems have been identified along the coastal bluffs at Cherry Point and along the west face of Lookout Mountain. While a slope failure at either site could result in substantial damage, considerably more damage could occur along the proposed route where the pipeline would cross four steep coastal bluffs.

### Mineral Resources

No significant difference in impacts.

## Soils

About 140 acres of soil would be permanently disturbed. Soil productivity would be lost by construction of facilities, dikes, and roads. The gradient of the land, along with retaining dikes would eliminate most erosion.

Fugitive dust losses at the storage facility site during construction would be in the range of 1.2 tons per acre per month and could be greatly reduced by regular watering.

Extending eastward from the storage site, the proposed route crosses a large glacial terrace plain with soils developed from glacial and post glacial outwash and recent alluvium. These soils are mostly of the Whatcom, Lynden, Norma, and Cagey series and occur on rolling topography. Textures are mostly silt loam, clay loam, and sandy loam. Permeabilities range from moderate to very slow.

The next segment constitutes soils that are deep silt loam and sandy loam alluvial and organic soils of the Nooksack, Puyallup, Semiahmoo, and Lynden series.

Extending farther eastward and turning southward for several miles into Skagit County, the route would traverse moderately deep and deep loam and sandy loam soils formed in weathered sandstone and shale. Principal series are Cathcart, Heisler, Barnhardt, and Barneston.

The next segment would extend southward to south of Mount Vernon. Principal soils are Puyallup, Puget, and Pilchuck series. These are deep loam, silt loam, and sandy loam soils formed in alluvial and glacial materials. Some of the best agricultural soils of western Washington occur within this part of the route.

Extending southward from Mount Vernon to Arlington the route would comprise soils of Alderwood, Cloquallum, Everett, and Bellingham series. These are moderately deep to deep sandy loam and silt loam soils formed in glacial materials. Topography is nearly level to hilly.

Vegetation would reestablish quickly in disturbed areas. Removal of vegetation on steeper slopes would result in annual soil loss in the range of 15 tons per acre. Erosion loss after revegetation would range from 1 ton per acre per year on the steeper slopes to 0.2 ton per acre per year on more level slopes.

Losses from fugitive dust during construction would be 80 to 100 pounds per acre of right-of-way, depending upon soil texture, soil moisture, and wind velocity. The application of water on the ground surface during construction would reduce this type of soil loss by at least 50 percent. Impacts caused by surface compaction by construction equipment would vary. Soils high in clay content would lose an estimated 5 percent of productive capacity. Coarse-textured and gravelly soils would be affected to a lesser extent.

Natural processes such as shrinking, swelling, freezing, thawing, root growth, and microbiological activity, along with plowing or ripping would return compacted soils to normal in 2 to 3 years.

Efforts to segregate and stockpile the topsoil would reduce profile mixing and dilution by an estimated 95 percent.

Impacts from oil spills would be similar to those described for the prime route (Chapter 3). Greatest impact would be from spills occurring on the nearly level and highly fertile alluvial lands.

## Aquatic Resources

### Physical Components

Nine major and several minor streams would be crossed by the proposed Cherry Point alternative alignment between the tank farm and Arlington. These include the Nooksack, Samish, Skagit, and the North and South Forks of the Stillaguamish. All exhibit seasonal discharge variations and generally have two high flow periods. One can be anticipated in fall or winter during periods of high precipation and the second during the spring when warming temperatures cause snowpack melt. Low flow periods usually occur in late summer. Flows generally are unregulated with the exception of the Samish, Skagit, and Tolt Rivers which have dams upstream of the proposed alignment. Water quality of all streams is Class A (excellent) or Class AA (extraordinary) as established by Washington State Water Quality Standards (WAC 173-201).

Several impacts to surface and ground water would result from construction and operation of the pipeline. Short-term increases of turbidity at and downstream of the river crossings would be expected. Construction during low flow periods, June through November, would minimize impact. Localized areas of shallow or perched ground water would be impacted by pipeline construction. Dewatering of the trench would affect natural ground water movement and sediment laden water could percolate to the water table, degrading water quality.

Hydrostatic test water would be withdrawn from several of the major streams along the pipeline route. Up to a 5 percent reduction of stream flow would be anticipated during withdrawal time.

No major impact from normal operation of the system would be anticipated. However, if a rupture of the pipe occurred oil could reach surface and ground water resources causing long-term water quality degradation. Many of the river crossings are within 5 miles of Puget Sound, so with a pipe rupture, oil would probably enter the marine environment.

Potential for impacts from oil spills on municipal supplies exists near Lake Whatcom.

### Biological Components

The pipeline route between Cherry Point and the proposed route near Arlington would cross approximately 15 streams important for migration, spawning, and rearing of salmon and searun trout. This would be approximately twice as many compared to the number of salmon streams crossed in the proposed route. Resident trout inhabit these streams and several additional streams not accessible to searun fishes. Major streams supporting searun fish populations include the Nooksack, Samish, Skagit and North and South Forks of the Stillaguamish River. Significant spawning areas for salmon and trout occur at the crossing areas on the following streams: Nooksack, Samish, and North and South Forks of the Stillaguamish. Salmon rearing facilities located along this corridor include the Whatcom Creek Rearing Facility and the Samish Hatchery which uses water from both Friday Creek and the Samish River. Hatcheries located upstream from the crossing areas include one on the Nooksack, two on the Stillaguamish and three on the Skagit River system.

Indian fisheries include the Lummi Indian River Fishery immediately downstream from the Nooksack River crossing area, a fishery in the marine waters near the mouth, and a gill net fishery located several miles upstream from the crossing area. The Tulalip Indian Beach Seine Fishery is located in Port Susan and relies partly on fish from the Stillaguamish system.

Reductions of salmon and trout populations would occur as a result of spawning gravel sedimentation. Sediment would come from instream trenching activities during construction and from streambank erosion during project operation. Most of the sediment from instream trenching would be washed out of the spawning gravel during the first period of high flow, but sediment from streambank erosion would continue for several years until revegetation was complete. The greatest reductions of salmon and trout populations would occur during construction and for the first few years of project operation. Several spawning cycles would be required for these populations to return to preproject levels. Reduced trout populations should recover in several years while salmon might take 20 years to fully recover. The initial population reductions during construction would probably not be noticed in the ocean sport, commercial, or Indian fisheries, but might be noticed in the river fisheries, if large numbers of year-class were eliminated. In subsequent years during project operation, population reductions would probably be within the normal range of fluctuations and consequently would not be noticed.

If an oil spill occurs during project operation, trout and salmon populations would be reduced for several miles downstream from the spill site. Several spawning cycles would be required for reduced populations to recover to prespill levels; several years for trout and up to 20 years for salmon. Population reductions would probably not be noticed in the ocean sport, commercial, or Indian fisheries, but might be noticed in the river fisheries, particularly following a large spill. Substantial fish losses would occur if large numbers of upstream, hatchery released juvenile fish are present during an oil spill. An oil spill upstream from the Whatcom Creek Rearing Facility or the Samish Hatchery could cause the loss of all eggs and juvenile fish at those facilities at the time of the spill.

## Marine Resources

### Physical Components

Maximum wave height in the Bellingham area may reach 5.5 feet between October and May. Areas in all parts of the San Juan Islands not exposed to waves from the Strait of Juan de Fuca have maximum wave heights of less than 4 feet. Exposed areas may experience waves and swells of the size prevailing in the strait. Wave heights are less than 2 feet in the Bellingham-San Juan Islands region from June to September (Oceanographic Institute of Washington 1974).

Tidal currents in the San Juan Archipelago can attain very high velocities because of numerous constrictions to tidal flow. Flood currents set northward through Haro Strait and ebb in the opposite direction. Ebb tide usually runs longer and has a higher tidal velocity than flood tide. At the northern entrance to Haro Strait flood tide sets eastward on both sides of Sucia Island and eastward across Alden Bank. Tidal velocities in Haro Strait are 1 to 5 knots (Oceanographic Institute of Washington 1974).

Between Sucia Island and Orcas Island the current develops moderate velocity. Heavy rip tides occur along the middle bank, north of it and around Discovery Island. Heavy, dangerous rip tides are prevalent between East Point and Patos Island and for 2 miles northward in the Strait of Georgia. The tidal currents in the Strait of Georgia are not as strong as those in the channels leading to and from the Strait of Juan de Fuca and current velocities can attain 3 knots at times, especially during the summer freshets (Oceanographic Institute of Washington 1974).

Marine water quality throughout the San Juan Archipelago, Haro and Rosario Straits, and the Strait of Georgia are classified extraordinary (Class AA). Bellingham Bay, Samish and Dilla Bay are considered excellent (Class A). (Washington State Department of Ecology 1977).

Estimated frequencies for oil spills, explosion, and fire associated with Cherry Point as an oil transshipment port are presented in table 9.4-1.

Oil spill trajectories for hypothethical in-transit or at berth oil spills in March and September are given in the Map Addendum. Since the Cherry Point spill site is close to the northern limits of the tidal current and wind boundaries, the trajectory results are very approximate. No estuarine flow sea breeze wind field were included in the model. In March the most probable impact area is the coast from Birch Point to Cherry Point. Southerly transport is possible due to inland high pressure system during this time of year. Under these conditions Orcas Island, Sucio Island, and Matia Island would be impacted. Also, East Point on Saturna Island, Canada would be threatened. Oil spills during September conditions would tend to travel rapidly to the northwest into Canadian waters. If the oil spills do not beach, the possibility exists that they would be entrained by Fraser River runoff. This might result in the spills being transported back into the region. Table 9.4-2 gives the approximate nautical miles of shoreline that might be initially impacted by spills at Cherry Point.

Expressions of probability are useful indicators of future events, but caution must be taken to avoid misinterpretation of these estimated values. "One spill every 'X' years" expresses a calculated rate and does not indicate when the spill may occur. Also, the estimate will remain valid only if conditions do not deviate significantly from historical patterns.

### Biological Components

Marine biological resources in the vicinity of Cherry Point include scallops, intertidal hardshell clams, sport salmon and nonsalmon fishing, commercial salmon gill net and purse seine fishing and commercial otter trawl areas for bottomfish. The distribution of these resources can be in the Map Addendum. To the north of Cherry Point are winter and spring Pacific herring spawning grounds and habitats for waterfowl. To the south are Pacific herring spawning grounds, Dungeness crab beds, and numerous waterfowl nesting and/or roosting habitats.

No major construction impact could be identified for this alternate port site.

During the operation phase chronic at-berth oil spills would degrade the water quality in the vicinity of Cherry Point. As a consequence, those marine resources of sports and commercial values could become tainted by seawater soluble fractions of crude oil.

## TABLE 9.4-1 ESTIMATED FREQUENCIES OF VARIOUS RISKS FOR OIL TRANSSHIPMENT FROM CHERRY POINT TO ARLINGTON

| Risk Involved | Estimated Existing Risks 1/ | Estimated Incremental Risks | | Estimated Combined Risks | | Estimated Incremental Risk for Onshore Pipeline | |
|---|---|---|---|---|---|---|---|
| | One Casualty Every: | 709,000 bbls/day One Casualty Every: | 933,000 bbls/day One Casualty Every: | 709,000 bbls/day One Casualty Every: | 933,000 bbls/day One Casualty Every: | 709,000 bbls/day One Casualty Every: | 933,000 bbls/day One Casualty Every: |
| Oil Spill: | | | | | | | |
| In-Transit (≥2.4 bbls) | 1.2 years (0.7-4.1) | 2.0 years (1.2-7.0) | 1.6 years (0.9-5.3) | 0.75 years (0.44-2.61) | 0.69 years (0.39-2.66) | | |
| At Fixed Berth (≥2.4 bbls) | 0.39 years (0.28-0.65) | 0.67 years (0.48-1.11) | 0.51 years (0.36-0.85) | 0.25 years (0.18-0.41) | 0.22 years (0.16-0.37) | | |
| At Single Point Mooring (≥3.6 bbls) | | | | | | | |
| Bunker Barge (≥2.4 bbls) | 0.27 years (0.17-0.58) | 1.56 years (1.00-3.40) | 1.18 years (0.76-2.58) | | | | |
| Tank Farm 2/ (≥2.4 bbls) | 0.19 years (0.16-0.24) | 0.96 years (0.78-1.3) | 0.59 years (0.48-0.76) | | | | |
| Pipeline 3/ (≥2.4 bbls) | 1.19 years (0.57-XX) | | | | | 6.88 years (3.29-XX) | |
| Explosion: | | | | | | | |
| In-Transit | 31 years | 53 years | 41 years | 26 years | 24 years | | |
| Harbor Area | 37 years | 63 years | 49 years | 24 years | 21 years | | |
| Fire: | | | | | | | |
| In-Transit | 35 years | 59 years | 46 years | 22 years | 20 years | | |
| Harbor Area | 15 years | | | | | | |
| Fire and Explosion | | | | | | | |
| Tank Farm ( $1,000) | | 64 years (42-133) | | | | | |
| Pipeline Station ( $1,000) | | 66 years (50-99) | | | | | |

Source: OIW 1978a,b,c, 1979a

1/ The ranges shown in parenthesis for each throughput are estimates of the 95 percent confidence limits.

2/ The estimated existing risk range shown in parenthesis is an estimate of the 97 percent confidence limit.

3/ The upper confidence limits are unpredictable and are indicated by "XX".

## TABLE 9.4-2 MOST LIKELY REGION OF FIRST OIL IMPACT FROM AN OIL SPILL AT CHERRY POINT

| Spill Site March Conditions | Approximate Nautical Miles of Shoreline | Spill Site September Conditions | Approximate Nautical Miles of Shoreline |
|---|---|---|---|
| Birch Point to Cherry Point | 10.0 | Birch Point to Cherry Point | 10 |
| Point Doughty to Racoon Point | 5.0 | | |
| Patos Island | 2.5 | | |
| Sucia Island | 9.0 | | |
| Matia Island | 2.0 | | |
| | 28.5 | | |
| East Point Suturna Island, Canada | 1.0 | | |

Source: Stewart 1978; Oceanographic Institute of Washington 1978d

A large in-transit or at-berth oil spill would present serious pollution problems in the Strait of Georgia. The oil-spill trajectories indicate that oil would also affect Canadian marine resources. Of significance would be a landfall of the oil at Sucia Island, a state wildlife refuge, and Matia Island, a national wildlife refuge and on the northern coastline of Orca Island. Alden Bank, a harbor seal area, would also be severely impacted. High mortality of herring and marine waterfowl would also be expected.

No significant marine impact would occur if the berths were removed during the abandonment phase.

### Terrestrial Vegetation

The vegetation of the tank farm and pipeline route is within the Willamette-Puget Forest ecoregion. The dominant species include Douglas-fir, western hemlock, big-leaf maple, and red alder. Riparian habitat found along the pipeline corridor include red alder, willow, black cottonwood, and birch as major components.

Assuming the tank farm would be similar to the proposal in acreage requirements about 140 acres of forest would be lost. This acreage would be out of timber production for at least 25 years.

No threatened or endangered plant species are known to occur in the vicinity of this proposed alternative corridor.

### Terrestrial Wildlife

The trumpeter swan, considered a threatened and endangered species by the State of Washington, may occur in the vicinity of Lake Terrell, a wildlife recreation area in the pipeline corridor. Bald eagle nesting sites near Neptune Beach may also be disturbed (Grub 1975).

Pipeline construction and corridor maintenance would cause reduction of waterfowl habitat and would remove 800 acres of wildlife environment along the 66 miles of pipeline. Long-term impacts could include drainage of marsh habitat and result in loss of nesting and staging areas. The proposed storage facilities would remove 80 acres of wildlife habitat.

Long-term effects from construction could be the loss of habitat and highly productive food areas and the possible disruption of a breeding season for species with naturally low reproductive rates.

Terrestrial mammals could also experience adverse effects in the event of pipe rupture and oil spillage. No endangered mammal species are expected to be adversely affected by the project.

### Cultural Resources

The cultural resource sites listed below would potentially be affected by use of Cherry Point and the associated pipeline route segment. There is high potential for discovery of additional archaeological and historical sites along the proposed pipeline corridor especially along the Lummi, Nooksack, Skagit, Pilchuck, and Stillaguamish River Valleys, near Samish Lake and along the smaller stream valleys.

TABLE 9.4-3 CULTURAL RESOURCE SITES, CHERRY POINT ALTERNATIVE

| County | Site Name | Site Type | Approximate Pipeline Mile |
|---|---|---|---|
| Whatcom | 45WH30 | Possible historic site | 3 |
| | 45WH57 | Prehistoric campsite | 11 |
| | 45WH18 | Prehistoric campsite | 12 |
| | 45WH9 | Prehistoric campsite | 12 |
| Skagit | 45SK68 | Type not known | 39 |
| | 45SK90 | Prehistoric campsite | 45 |
| | 45SK117(Avon) | Town with historic structures | 46 |
| | 45SK112(Mt.Vernon) | Town with historic structures | 47 |
| | 45SK40 | Shell mound | 50 |
| | 45SK64 | Shell mound | 50 |
| | 45SK65 | Prehistoric artifact locality | 51 |
| | 45SK41 | Shell mound | 51 |

Potential impacts to sites would be the same as those discussed in Chapter 3.

### Visual Resources

The onshore storage facility would cause high visual impact for the short-term that would diminish as it blended into the existing oil-related industrial complex.

The construction of a 42-inch pipeline, paralleling the existing 20-inch Trans Mountain pipeline, from Cherry Point to a point near Arlington, would cause moderate visual impact as it traversed the mixed urban, suburban community. Impacts during the operation phase would diminish and be low for the life of the project. An oil spill of any magnitude within the Sound would have severe impacts on visual resources such as estuaries and beaches.

### Land Use

Existing land use at Cherry Point is dominated by the Mobil and Arco oil refineries. In the surrounding area there is an extensive patchwork of small farms. Whatcom County has applied a "general protections" zoning designation to the area; the comprehensive plan designates the area as "primary industrial." The port facility would be consistent with existing, zoned and planned land uses. No significant impacts are likely to occur.

The pipeline route to the Arlington area would involve construction through numerous areas where development has reached densities that must be considered urban. The impacts to the developed land within the construction right-of-way would be essentially as described in chapter 3. The pipeline right-of-way would affect about the same amount of agricultural land and less forest land than the primary route. Impacts to these land uses are not likely to be significant.

Areas with special management concerns include the Lummi Indian Reservation located about 3 miles south of the tanker berthing and onshore storage facilities. The pipeline route, paralleling the Trans Mountain pipeline, would be about a half mile north of the reservation boundary. Significant adverse impacts to the Lummi Reservation would likely occur only in the event of a major oil spill at the tanker berthing facility which could result in oil damage to the reservations, beaches, and agriculture.

### Transportation and Utility Networks

Tanker traffic to the Cherry Point berthing facility would transit the Strait of Juan de Fuca and Rosario Strait before entering the Strait of Georgia where the berths would be located. At 933,000 barrels per day throughput, tanker traffic through Rosario Strait would represent a 42 percent increase over 1976 tanker traffic to Cherry Point refineries assuming that the current 125,000 dead weight tonnage tanker size limit is eliminated. This increase in vessel traffic would significantly increase the risk of a tanker casualty and resulting oil spill.

The Cherry Point area is served by a network of primary and secondary roads that would be adequate for peak traffic conditions which would occur during construction.

Two major rail lines, the Burlington Northern and the Milwaukee railroad provide service to this area. Rail service should be adequate for hauling project materials and no significant impacts to these systems would be expected. The Bellingham International Airport provides commuter air service to the area. It has ample capacity for any air traffic which might be induced.

Electric transmission facilities are present in the area to serve the INTALCO Aluminum Plant, the other refineries and the Trans Mountain pipeline system. Puget Sound Power and Light, a private utility, provides service to this area. Representatives of the company have expressed reluctance to contract additional firm power service because of possible shortages in hydro generation, coupled with delays in getting thermal generation on line. This alternative should require approximately 20 to 25 megawatts per year less power than the proposed route.

## Recreation

No significant impacts to recreational activities are anticipated as a result of normal construction, operation, or abandonment activities associated with the berthing, onshore storage facility, or pipeline system. No developed recreational areas are known to be crossed by the pipeline.

Sport fishing for searun trout and salmon is done on most streams throughout the alternative corridor; angler use at pipeline crossings is not known. Impacts to anglers would be indirect and related to impacts on the fish.

Two rivers which are included in the Washington State Shorelines Management Act of 1971 as "Rivers of Statewide Significance" are crossed by the proposed pipeline; these are the Nooksack (crossed twice) and Skagit Rivers. Trenching activities across these rivers would detract from scenic and recreational uses.

An oil spill at sea would severely impact angling for fin and shellfish, and other Puget Sound marine-related recreational activities because of oil contamination. See map section II (map addendum) for location of recreation related marine resources.

Preliminary risk analysis studies indicate that an oil spill off Cherry Point would affect sport salmon fishing north of Orcas Island. Nonsalmon sport fishing would be impacted from Boundary Bay to the vicinity of Orcas Island. Area shellfish beds would be contaminated by the oil and could take an estimated 4 to 10 years to recover before recreational collection could resume. Area utilization is not significant. A recreational home development in the Birch Bay vicinity would be damaged by oil polluted beaches and loss of visual quality. A minimum of 20 shoreside recreational parks and marinas could be impacted. Oil-fouled gear and boats and diminished recreational suitability could affect an estimated 80,000 to 160,000 recreationists if a spill occurred between June and August, curtailing use for 30 days.

## Social and Economic Conditions

The Cherry Point alternative would affect Whatcom, Skagit, and Snohomish Counties. The area is largely urban and industrial, with oil-related industries currently operating. Urban areas include Bellingham, which is 12 miles from the proposed port facility, Anacortes, Mount Vernon, Everett, and Seattle-Tacoma.

Population increases would be small in Whatcom and Skagit Counties. Construction would bring 600 people to Whatcom County and 130 to Skagit County. That would represent increases over the projected 1980 population (100,200 and 57,600) of 0.6 percent and 0.2 percent respectively. It is estimated that about 165 people would move to Whatcom County and 35 to Skagit County during operation.

Population increases along the route to Arlington would be small and short-term. Most workers would be expected to reside in the large urban areas, and could be accommodated there. The increase in personal income from construction would be $18.4 million (1977 dollars) in Whatcom County, an increase of about 3.5 percent.

In Skagit County the increase in personal income would be $5.2 million, about 1 1/2 percent. Assessed value in Whatcom County would increase by about $92 million because of the port and pipeline facilities. That would be an increase of 5.6 percent over the 1977 assessed value of $1,653 million. Skagit County would realize an increase of $6 million from the pipeline, an 0.6 percent increase over 1977 county valuation.

No major impacts would be expected on community infrastructures. The housing market would be strained in Whatcom and Skagit Counties during construction, but workers could probably be accommodated. If a planned nuclear plant were under construction concurrently with the port construction, housing impacts would increase. Schools would also be strained since they are currently operating at capacity. These impacts would be low and short-term. Since the area already has a heavy industrial worker base, local residents are accustomed to the type of activity the project would entail.

## BURROWS BAY

### Description

This alternative considers a terminal at Burrows Bay, where all crude arriving by tanker would be unloaded and moved by pipeline to the onshore storage facilities (figure 9.4-4). The location of a port at Burrows Bay would entail the construction of a sea island type berth, a marine pipeline to shore, and a tank farm of 10-day storage capacity.

Construction would entail underwater work to seat pylons for the berth and installation of a 7,000-foot long submarine pipeline causing some sea bottom alteration. Irreversible shoreline alterations would be related to pumping facilities, pipeline location, and siting of a tank farm. The laying of a 7-mile pipeline across Fidalgo Island would require road and powerline construction. The pipeline would not cross any major rivers, but would cross two creeks.

The pipeline would continue east to Arlington, Washington, joining the proposed route.

Construction of a transshipment port at Burrows Bay is prevented by an amendment to The Marine Mammal Protection Act (Public Law 95-136, 1977).

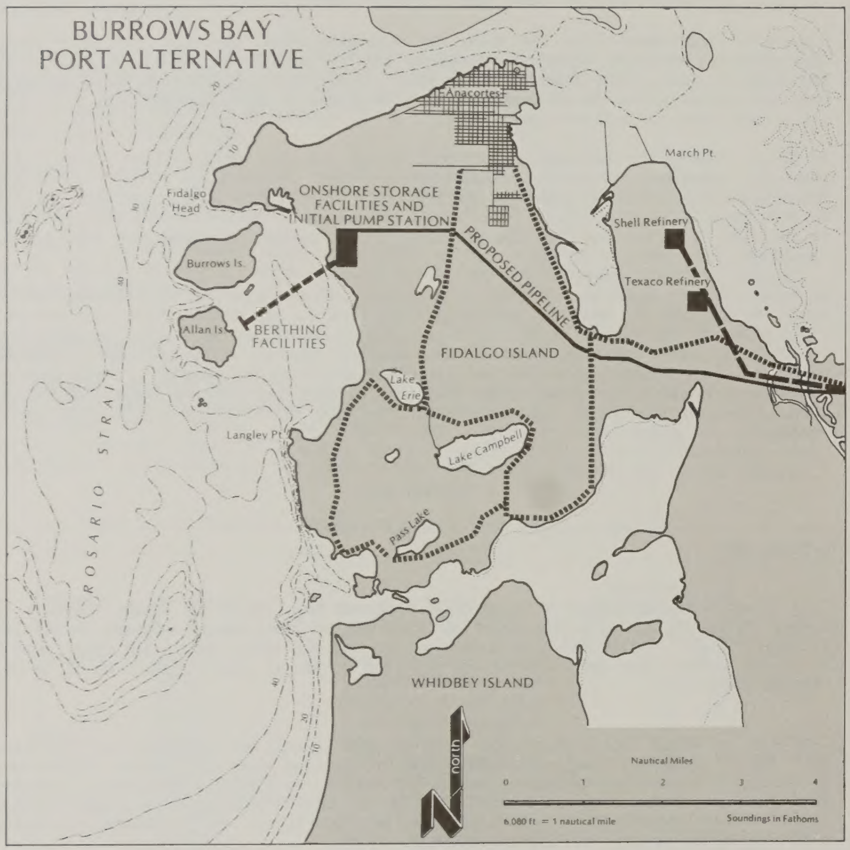

Figure 9.4-4

Northern Tier Pipeline Company

## Climate and Air Quality

No impacts on climate are anticipated for this alternative port site.

Dispersion conditions for air pollutants in the Burrows Bay area are generally good. Winds are predominantly either from westerly directions or from directions between east and south-southeast. Westerly winds are most common in summer, whereas westerly winds are more common in winter. Neutral or unstable atmospheric conditions exist about 70 percent of the time. Stable conditions occur about 30 percent of the time. There is little data available on vertical temperature profiles or temperature inversions.

Existing industrial emission sources in the vicinity of the alternative port site include two refineries, which emit significant quantities of sulfur dioxide, nitrogen oxides, particulates, and hydrocarbons. Air quality data taken at Anacortes and nearby March Point indicate, however, that sulfur dioxide concentrations are well within federal and state standards. Results of air quality modeling performed by SAI (1978) for this alternative port site are given below.

The sulfur dioxide modeling results indicate that 24-hour, Class II incremental standard would not be exceeded if a 1.0 percent maximum sulfur content for bunker fuel were used. The highest calculated annual average concentration would be 5.0 ug/m$^3$, which is 25 percent of the maximum allowable Class II increment.

Calculations for existing sources and tanker emissions resulted in concentrations of 278 ug/m$^3$, 229 ug/m$^3$, and 115 ug/m$^3$ for the maximum 1-hour, 3-hour, and 24-hour sulfur dioxide average concentrations, respectively. These are well within the federal and state air quality standards. The contribution to sulfur dioxide concentrations from the tankers alone would be considerably lower. The highest calculated annual average sulfur concentration is 16.0 ug/m3 for existing sources only, and 18.0 ug/m3 for the combined impact of existing and proposed sources. Thus the increase in sulfur dioxide concentrations would be relatively small. The concentrations would be well within the State of Washington Air Quality Standard of 53 ug/m3.

The maximum 24-hour average particulate concentration caused by this alternate port is 4.7 ug/m3. This is well within the Class II increment of 37 ug/m$^3$. The annual average concentration is estimated to be less than 1 ug/m$^3$, which is well within the Class II incremental standard of 19 ug/m$^3$.

The highest annual average concentration of nitrogen oxides, combining effects of proposed sources and existing sources, is 2.0 ug/m$^3$. This compares with a value of 1.8 ug/m$^3$, if only existing sources are considered. Thus the increase in levels of nitrogen oxides from this alternate proposal would be relatively small.

There was no ozone modeling performed for this alternative port site. However, since project emissions at the Burrows Bay site would be similar to those at Port Angeles, ozone impacts would be about the same as for the Port Angeles site (SAI 1978). Little change in ozone concentrations would occur in the vicinity of the berthing facilities. Ozone concentrations downwind of the onshore storage facilities might be increased by about 10 percent above background levels when conditions were favorable for ozone formation. However, it is not likely that this increase would cause any violation of the Federal ozone standard.

for ozone formation. However, it is not likely that this increase would cause any violation of the Federal ozone standard.

## Noise

The construction of the berthing facilities and submarines pipeline would result in a noticeable increase in noise experienced by residents nearest the shoreline. Highest noise levels would occur during pile driving operations. Noise would be mostly confined to daytime hours.

Construction of the onshore storage facilities would cause daytime noise levels of between 60 and 70 dBA at residences nearest the construction site. Noise would be mainly limited to daytime hours.

Construction of the pipeline would cause noise levels of up to 65 dBA for residences located within 1,000 feet of the alignment. The most intense noise would occur over a period of about 5 days, and would be mainly limited to daytime hours.

During the operation phase the primary noise source would be electric pump station motors. Noise levels would be about 58 dBA at a distance of 400 feet. To some nearby residences, this might represent a slight increase above background noise levels.

## Topography and Geology

This port segment alternative is characterized by moderate to steep terrain at Burrows Bay (Burrows Bay pipeline mile 0 to 7) and relatively gentle terrain for the remaining 31 miles to Arlington. While the proposed port and pipeline route would not encounter quite as much steep terrain, it would involve a 20+ mile submarine crossing, which results in more disturbed acreage than on dry land. Consequently, topographic impacts--minor landform changes and drainage alterations--would be slightly greater along the proposed route and at the proposed port.

Geologic material encountered at this alternate port site would consist of hard, dense, crystalline rock and upper Mesozoic sedimentary and volcanic rocks and the pipeline route would encounter Quaternary glacial and alluvial material with some outcrops of Tertiary sedimentary rocks. While the geologic material encountered at the proposed port and along the proposed pipeline would not be exactly the same as the Burrows Bay-Arlington alternative, geologic impacts would be similar and would consist of the excavation of large volumes of geologic material and some excavation-induced (including blasting) changes in the physical characteristics of the material (e.g., inherent rock strength, porosity and permeability). However, as the proposed route would involve a marine crossing, substantially more geologic material would be excavated and the resultant impacts would be slightly greater.

### Geologic Hazards

Slope instability and seismicity would be the only geologic hazards that would be encountered at this port alternative and pipeline route.

This alternate port and pipeline route segment alternative, like the proposed port and pipeline route, is located in an area of moderate to high seismic activity that corresponds to a Seismic Risk Zone 3 (maximum earthquake damage expected). However, no known active or potentially active faults or large magnitude earthquakes (6+ on the Richter scale) have been identified within 25 miles of this alternate port site and pipeline. While no large magnitude earthquakes have occurred within 25 miles of the proposed port or pipeline, the region has recorded a higher level of seismicity than the region around Burrows Bay. In addition, an inferred potentially active fault has been identified within 2 miles of the proposed port site and the geologic material at the proposed site, being weaker and less consolidated than the material at Burrows Bay, is less seismically stable. Consequently, the overall impacts from earthquakes would be greater at the Port Angeles port site and along its pipeline than at the Burrows Bay alternate port and pipeline.

As the Burrows Bay site is composed of crystalline rock, the harbor bottom has a very gentle gradient (less than 1 percent) and the pipeline would cross relatively gentle terrain, no slope instability problems have been identified. Consequently, impacts would be much less than at the proposed port site at Port Angeles and along the proposed pipeline route.

### Mineral Resources

No significant difference in impacts.

## Soils

The potential site would be composed of loamy soils that are mostly shallow, very rocky, and overlying serpentine bedrock. Slopes range from strongly sloping to steep. Removal of vegetation on the steep slopes would result in potential soil losses of 8 to 10 tons per acre per year, if mitigation measures such as drainage diversion channels and sedimentation ponds are used. Soil losses after revegetation would be reduced to about 0.50 tons per acre per year.

Soil compaction by construction vehicles would reduce soil productivity by an estimated 5 percent and would persist for about 2 years after construction.

Topsoil segregation would reduce impacts from profile mixing. Permanent loss of fertility would be 5 to 10 percent. Natural fertility of soils within the site is low.

Soils in western Washington for the most part are deficient in nutrients because of leaching by precipitation. Vegetation would reestablish quickly in disturbed areas. Removal of vegetation on the steeper slopes would cause soil losses of approximately 15 tons per acre per year. Annual soil losses on lesser slopes would be in the range of 2 to 4 tons per acre. Erosion after revegetation would range from 1.00 tons per acre per year on the steeper slopes to 0.20 tons per acre per year on the more level slopes. Losses from fugitive dust during construction would be 80 to 100 pounds per acre of right-of-way, depending upon soil texture, soil moisture, and wind velocity. The application of water on the ground surface during construction would reduce this type of soil loss by at least 50 percent.

Surface compaction by construction equipment would have varying degrees of impact. Silt loam and silty clay loam textures would lose an estimated 5 percent productive capacity. Coarser textures and gravelly soils would be affected to a lesser extent. Natural weathering and biological processes, along with plowing or ripping would return compacted soils to normal in 2 to 3 years.

Some profile mixing would occur regardless of efforts to segregate and stockpile the topsoil. Estimated loss of fertility would be 5 percent.

Oil spill impacts would be similar to those described for the prime route. Greatest impact would be on the more fertile, nearly level alluvial lands in the southern part of the segment.

## Aquatic Resources

### Physical Components

Two major and several minor streams would be crossed by the pipeline between Burrows Bay and Arlington. These include the Skagit and North Fork of the Stillaquamish River. Seasonal variation of river flow could be anticipated for all the east Puget Sound rivers. High flow periods generally occur in late fall or early winter and again in spring. Low flows generally occur between March and November. Flows generally are unregulated with the exception of the Skagit River which has a dam upstream of the proposed crossing. Water quality of streams along the alignment are Class A (excellent) or Class AA (extraordinary) by Washington State Water Quality Standards.

Construction and operation of the pipeline would impact surface and ground water resources. Short-term increases of turbidity at and downstream of the river crossing would occur. Construction during low flow would minimize impact. Localized perched and shallow ground water regions would be affected by pipeline construction. Dewatering of the trench would affect natural ground water movement, and sediment laden water would percolate to the water table, degrading water quality. Hydrostatic test water would be withdrawn from one or several rivers along the alignment. Base flow of the stream during withdrawal periods would be reduced 1 to 5 percent. No major impact from normal operation of the system would be anticipated. However, if pipeline rupture should occur oil would be released to surface and/or ground water resources degrading water quality. Most river crossings are within 20 miles of Puget Sound, so potential for spilled oil reaching the marine environment exists. Municipal ground water supplies near the towns of Stanwood and Hartford would be affected.

### Biological Components

The pipeline route between Burrows Bay and Arlington would cross seven streams important for migration, spawning, and rearing of salmon and searun trout. This would be fewer than the number of salmon streams crossed in the proposed route. Resident trout also occur in these streams and in several additional streams not accessible to searun fishes. Major streams supporting searun fish populations include the Skagit and North Fork of the Stillaguamish River. Significant spawning areas for salmon and trout occur at the crossing areas on the North Fork of the Stillaguamish River. Hatcheries located upstream from the crossing areas include two on the Stillaguamish and three on the Skagit River system. The Tulalip Indian Beach Seine Fishery located in Port Susan harvests fish from the Stillaguamish River system. Sport angling for salmon and trout occurs on most streams throughout the region.

Reductions of salmon and trout populations would result from sedimentation of spawning gravel. Sediment would come from upstream trenching activities during construction and from streambank erosion during project operation. Most of the sediment from instream trenching would be washed out of the spawning gravel during the first period of high flow, but sediment arising from streambank erosion would continue for several years. The greatest reductions to salmon and trout populations would occur during construction and for the first few years of project operation. Several spawning cycles would be required for these populations to recover to preproject levels. Reduced trout populations should recover in several years while salmon might take 20 years to fully recover. The population reductions because of construction would probably not be noticed in the ocean sport, commercial, or Indian fisheries, but might be noticed in the river fisheries if large numbers of one year-classes were eliminated. During project operation, reductions would probably be within the normal range of population fluctuations and consequently would not be noticed.

Fish populations would be reduced if an oil spill occurred during project operation. Trout and salmon populations would be reduced for several miles downstream from the spill site. Several spawning cycles would be required for reduced populations to recover to prespill levels; several years for trout and up to 20 years for salmon. Population reductions would probably not be noticed in the ocean sport, commercial, or Indian fisheries, but might be noticed in the river fisheries, particularly following a large spill. Substantial fish losses would occur if large numbers of upstream, hatchery released juvenile fish were present during an oil spill.

## Marine Resources

### Physical Components

Entrance to Burrows Bay can be achieved through channels between Fidalgo Head and Burrows Island (controlling depth of 90 feet); between Burrows Island and Allan Island (controlling depth of 108 feet); between Allan Island and Williamson Rocks (controlling depth of 198 feet); or between Williamson Rocks and Langley Point (controlling depth of 196 feet).

Between October and May, areas sheltered from the Strait of Juan de Fuca would experience maximum wave heights of less than 4 feet. Exposed areas might experience waves prevalent in the eastern Strait of Juan de Fuca. The tidal currents and tidal ranges within Burrows Bay would be similar to those at the entrance to Rosario Strait and in the Strait of Juan de Fuca. Currents may attain speeds of 2 to 5 knots varying with the tidal range and the influence of wind (Oceanographic Institute at Washington 1974).

Water quality at the entrance to Rosario Strait and within Burrows Bay is extraordinary (Class AA) (Washington State Department of Ecology 1977).

Estimates of existing, incremental, and combined oil spill risks and explosion and fire risks, associated with Burrows Bay, for various transshipment operations are presented in table 9.4-4. The pipeline risks are for combined offshore and offshore pipeline to Arlington. Further risk dicussion can be found in chapter 3.

Tankers approaching Burrows Bay, via the north bound traffic lane, must pass over a rapidly shoaling area between Point Colville and Lawson Reef. It is in this shoaling area that a hypothetical in-transit tanker grounding is considered to occur in March and September. The oil-spill trajectories for these two hypothetical incidences are shown in the Map Addendum. Shorelines that could initially be impacted during a March oil spill are Allans Island, Burrows Bay, Iceberg Point to Decatur Head, and Smith Island. A September oil spill could initially impact Allan Island, Burrows Island, and Iceberg Point to Decatur Head.

The hypothetical oil spill trajectories for in-transit casualties off Langley Point, Fidalgo Island, in March during spring and neap tidal conditions, are shown in figures 9.4-5 and 9.4-6. The oil spill trajectories during a spring tide indicate that Allan Island would be impacted in 6 hours, and Burrows Island and Flounder Bay would be impacted within 10 hours. A similar in-transit oil spill during neap tidal conditions would impact Flounder Bay within 2 hours and the coastline of Fidalgo Island from Flounder Bay to Langley Point between 3 to 8 hours.

## Biological Conditions

Marine habitats found in Burrows Bay are eelgrass beds, rock, mud, and open ocean. Waterfowl are numerous and the salmon population is high. In the northern part and southern entrance of the bay commercial purse seine fisheries are concentrated. Salmon gill net fishing is concentrated only in the southern approach. Sport salmon fishing is found throughout the bay and bottom fishing can be found around Allan and Burrows Islands and in all passages into the bay. Shrimp are also found within the bay. The general distribution of these resources in Burrows Bay and adjacent Rosario Strait and Strait of Juan de Fuca can be found on maps (Map Addendum).

Specific locations of marine waterfowl and mammal poplulations in the vicinity of Burrows Bay are shown in Map Addendum.

During the construction of the submarine pipeline, degradation of marine water quality would occur within Burrows Bay, the entrance to Rosario Strait and the eastern portion of the Strait of Juan de Fuca. Suspended solids, organic debris, heavy trace metals, chlorinated hydrocarbons would all contribute to this degradation. Details on construction impact of submarine pipeline construction can be found in chapter 3.

Chronic oil spills would be expected during in-transit and at-berth operations. Such spills would degrade the water quality in the bay and the adjacent straits. A pipeline rupture would have a severe impact upon the Bay, the San Juan Archipelago, and Whidbey Island. Water Quality in the northeastern part of the Strait of Juan de Fuca and throughout Rosario Strait would be degraded for the duration of the spill. Specific information on effects of crude oil can be found in chapter 3.

TABLE 9.4-4 ESTIMATED FREQUENCIES OF VARIOUS RISK FOR OIL TRANSSHIPMENT FROM BURROWS BAY TO ARLINGTON

| Risk Involved | Estimated Existing Risk 1/ | Incremental Risk | | Combined Risk | |
|---|---|---|---|---|---|
| | | 709,000 bbls/day | 933,000 bbls/day | 709,000 bbls/day | 933,000 bbls/day |
| | One Casualty Every: | One Casualty Every: | | One Casualty Every: | |
| Oil Spill: | | | | | |
| In-Transit (≥2.4 bbls) | 1.2 years (0.7-4.1) | 2.5 years (1.2-7.0) | 1.6 years (0.9-5.3) | 0.81 years (0.48-2.80) | 0.74 years (0.43-2.54) |
| At-Fixed Berth (≥2.4 bbls) | 0.39 years (0.28-0.65) | 0.67 years (0.48-1.12) | 0.51 years (0.36-0.85) | 0.25 years (0.18-0.41) | 0.22 years (0.16-0.37) |
| Bunker Barge (≥2.4 bbls) | 0.27 years (0.17-0.58) | 1.56 years (1.00-3.40) | 1.18 years (0.76-2.58) | | |
| Tank Farm 2/ (≥2.4 bbls) | 0.19 years (0.16-0.24) | 0.96 years (0.78-1.3) | 0.59 years (0.48-0.76) | | |

March 1976, Spring Tide

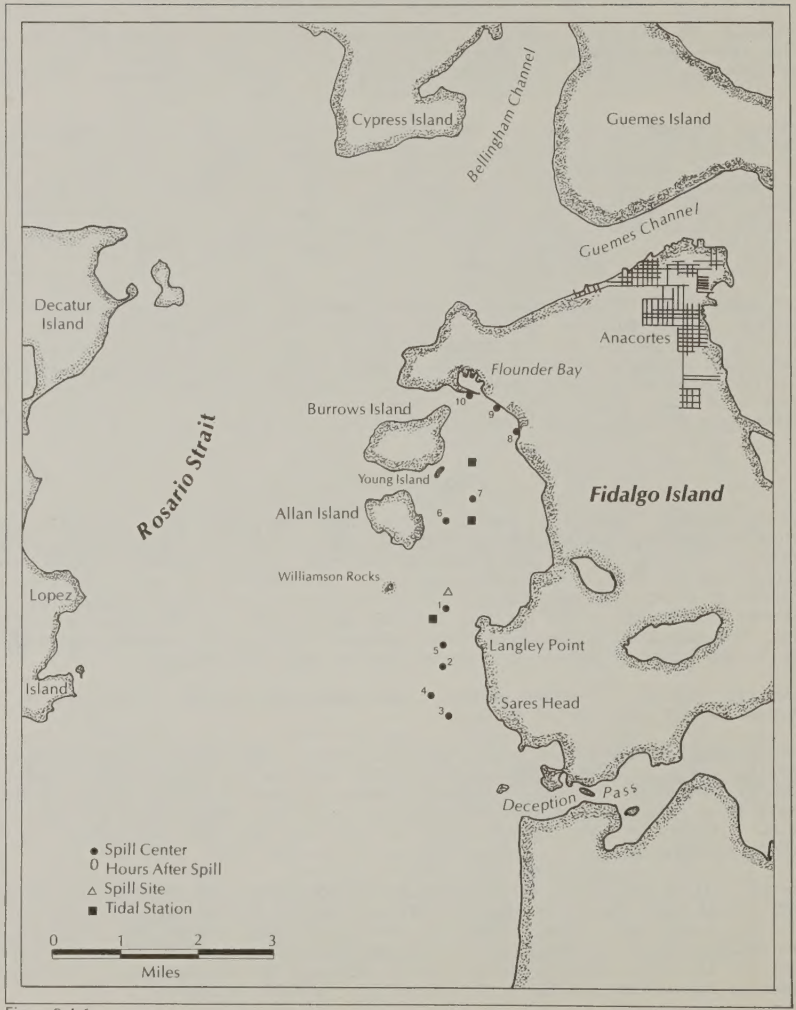

Figure 9.4-6

Source: Oceanographic Institute of Washington

### Terrestrial Vegetation

The vegetation of the storage facility and along the pipeline corridor is in the Willamette--Puget Forest ecoregion. The dominant overstory components include Douglas-fir, western hemlock, big-leaf maple, and red alder.

No endangered or threatened plant species are known to occur within the storage facility or pipeline corridor.

### Terrestrial Wildlife

Migratory waterfowl and other birds using the Pacific flyway would be impacted by the disturbance of staging areas and alteration of wildlife habitat. The pipeline would remove vegetation from approximately 460 acres including potential nesting and roosting areas for endangered species e.g., bald eagles and peregrine falcons. Oil spills could also impact the habitat used for waterfowl breeding and nesting.

### Cultural Resources

The cultural resource sites showin in table 9.4-5 would potentially be affected if this proposed port alternative and pipeline route segment were used. There is high potential for discovery of additional archaeological and historical sites in the proposed construction areas, especially along the shoreline and the Skagit, Pilchuck, and Stillaguamish River valleys. Potential impacts to these sites would be the same as those discussed in Chapter 3.

### Visual Resources

The Burrows Bay alternative is located in an inlet sheltered by Burrows Island and Allan Island to the west. The berthing facilities are planned for the northeast side of Allan Island with submarine pipelines to Fidalgo Island 1/2 mile northwest of Alexander Beach. There would be a tank farm at Fidalgo Island. Assuming that the shoreline across which these submarine pipelines would ascend to the tank farms is a low, rocky cliff, or at best gravelly sand-soil composite, a high visual impact would be evident, especially during construction. It would persist beyond the life of the project.

High visual impacts could result during construction, if dredging is necessary to deepen the berthing facilities for large tankers. The berthing and unloading operation should cause little impact because of its distance from the shoreline. Tankers are common in the area.

The onshore tank farm would require approximately 140 acres and could have high visual impact during construction because of dust emissions. Because of the present oil-related industry in the area, the addition of a tank farm would have minor impacts on the existing scene.

### Land Use

At Burrows Bay the port and onshore storage facility would introduce an industrial land use to the relatively undeveloped coastline. The alternative would result in more urban growth near Anacortes than the NTPC proposal would in Port Angeles. The conversion of existing land uses to project use might be viewed as more severe in view of the more limited availability of land. The project might not be consistent with the County Shoreline Master Program. The pipeline route would cross about 1/2 mile of tidelands at the end of Padilla Bay, claimed by the Swinomish Indians to be part of their reservation. The various land uses affected by the pipeline route would be in the same proportion as the Cherry Point alternative and the impacts would be comparable.

TABLE 9.4-5 CULTURAL RESOURCES--BURROWS BAY ALTERNATIVE

| County | Site Name | Site Type | Approximate Location |
|---|---|---|---|
| Skagit | 45SK16 | Shell midden | On Allan Island |
| | Burrows Island light station* | Historic lighthouse | On Burrows Island |
| | 45SK42 | Shell mound | On Fidalgo Bay |
| | 45SK43 | Shell mound | On Fidalgo Bay |
| | 45SK45 | Shell mound | On Fidalgo Bay |
| | 45SK 1 | Shell mound | On Similk Bay |
| | 45SK17 | Shell midden cairn and burials | On Similk Bay |
| | 45SK18 | Shell midden | On Similk Bay |
| | 45SK58 | Campsite | Pipeline mile 12 |
| | 45SK67 | Artifact locality and possible trail | Pipeline mile 13 |
| | 45SK90 | Habitation | Pipeline mile 14 |
| | 45SK117 (Avon) | Town with historic structures | Pipeline mile 17 |
| | 45SK112 (Mt. Vernon) | Town with historic structures | Pipeline mile 18 |

| | 45SK64 | Shell mound | Pipeline mile 21 |
| | 45SK65 | Prehistoric artifact locality | Pipeline mile 22 |
| | 45SK41 | Shell mound | Pipeline mile 22 |

*Listed in National Register of Historic Places.

### Transportation and Utility Networks

Because of its closeness to the Strait of Juan de Fuca, Burrows Bay would likely have less navigation risk than Cherry Point. Vessel traffic congestion would not likely be a problem.

Highway access to Burrows Bay is limited to a 2-lane roadway from Anacortes. Construction traffic would cause significant lowering of service levels on roadways and in nearby Anacortes where the nearest railroad is located. Traffic congestion would probably be more severe than in Port Angeles as described in chapter 3.

Electric power requirements would be similar to the Cherry Point alternative and would have a comparable potential impact in terms of regional electric power supplies.

## Recreation

No significant impacts to recreational activities are anticipated as a result of normal construction or abandonment activities associated with the berthing, submarine pipeline, or connecting pipeline system. The Skagit River pipeline crossing occurs in an area designated for high scenic and recreational values (Shoreline Management Act 1971). An oil spill in Puget Sound and pipeline leaks or ruptures would curtail recreational activities for the period of contamination. Bottom and salmon fishing in Burrows Bay, recreational shrimping and scuba diving are some of the activities which could be affected. Preliminary studies indicate that if a tanker oil-spill incident occurred at the entrance to Rosario Strait, it could impact sport salmon fishing south of Lopez Island and offshore Whidbey Island. Nonsalmon sport fishing south of Lopez Island and along Whidbey Island could be impacted for the short-term. Casual recreational marine pursuits would be lost for the short-term and a significant number of recreationists affected if a spill occurred during the summer season. Oil fouling of gear and boats would be the most critical impact. For locations of area recreational activities, see the Map Addendum.

## Social and Economic Conditions

The counties which would be affected by this alternative are Skagit and Island; they would be most impacted by port construction. Snohomish County would be impacted by pipeline construction. Whatcom County would also be expected to have impacts.

During construction, population increases would be less than 1 percent over the projected 1980 figures. Skagit County would have an increase of 540 people, Island would increase by 130, Whatcom by 260, and Snohomish by 610. During operation Skagit County would increase by 100 people, Island by 35, Whatcom by 50, and Snohomish by 15. Population increases would be less significant than those expected for the primary proposal.

Increases in personal income are listed in table 9.4-6.

These increases would be positive but not significant impacts for the four counties.

Assessed value in Skagit County would increase by $98 million dollars because of the port facilities. This represents a 9 percent increase over the 1977 valuation for the county.

Housing stocks are presently limited in Skagit and Island Counties. Impacts on housing would probably be low during construction because workers could find accommodations in neighboring areas within commuting distance.

Most of the schools in the area are presently operating above capacity, and would be further strained by additional students brought in by the project. Skagit County would have an estimated 90 additional students during construction. Ninety more students would be distributed over the schools in Island, Whatcom, and Snohomish Counties during construction.

TABLE 9.4-6 INCREASE IN PERSONAL INCOME

| County | | Increase in Personal Income ($Millions) | Change at Annual Rates (1977 Dollars) (Percent) |
|---|---|---|---|
| Skagit | Construction | 13.6 | 4.0 |
| | Operation | 1.0 | 0.3 |
| Island | Construction | 3.7 | 2.2 |
| | Operation | 0.4 | 0.2 |
| Whatcom | Construction | 9.1 | 3.1 |
| | Operation | 0.5 | 0.1 |
| Snohomish | Construction | 21.1 | 1.3 |
| | Operation | 0.2 | NC |

N.C. = Negligible change

Oak Harbor in Island County would experience strain on its fire, police, and medical facilities during construction. Fire protection in Anacortes (Skagit County), the nearest city to the port facilities, would be insufficient to handle port-related emergencies during operation of the system. Other community services would not be significantly impacted.

The impacts of the Burrows Bay alternative could be drastically increased if a nuclear power plant which is planned near Sedro-Wooley were under construction at the same time as the port. The plant is tentatively scheduled for construction beginning in 1979, but could be delayed to 1982.

# FRESHWATER BAY

## Description

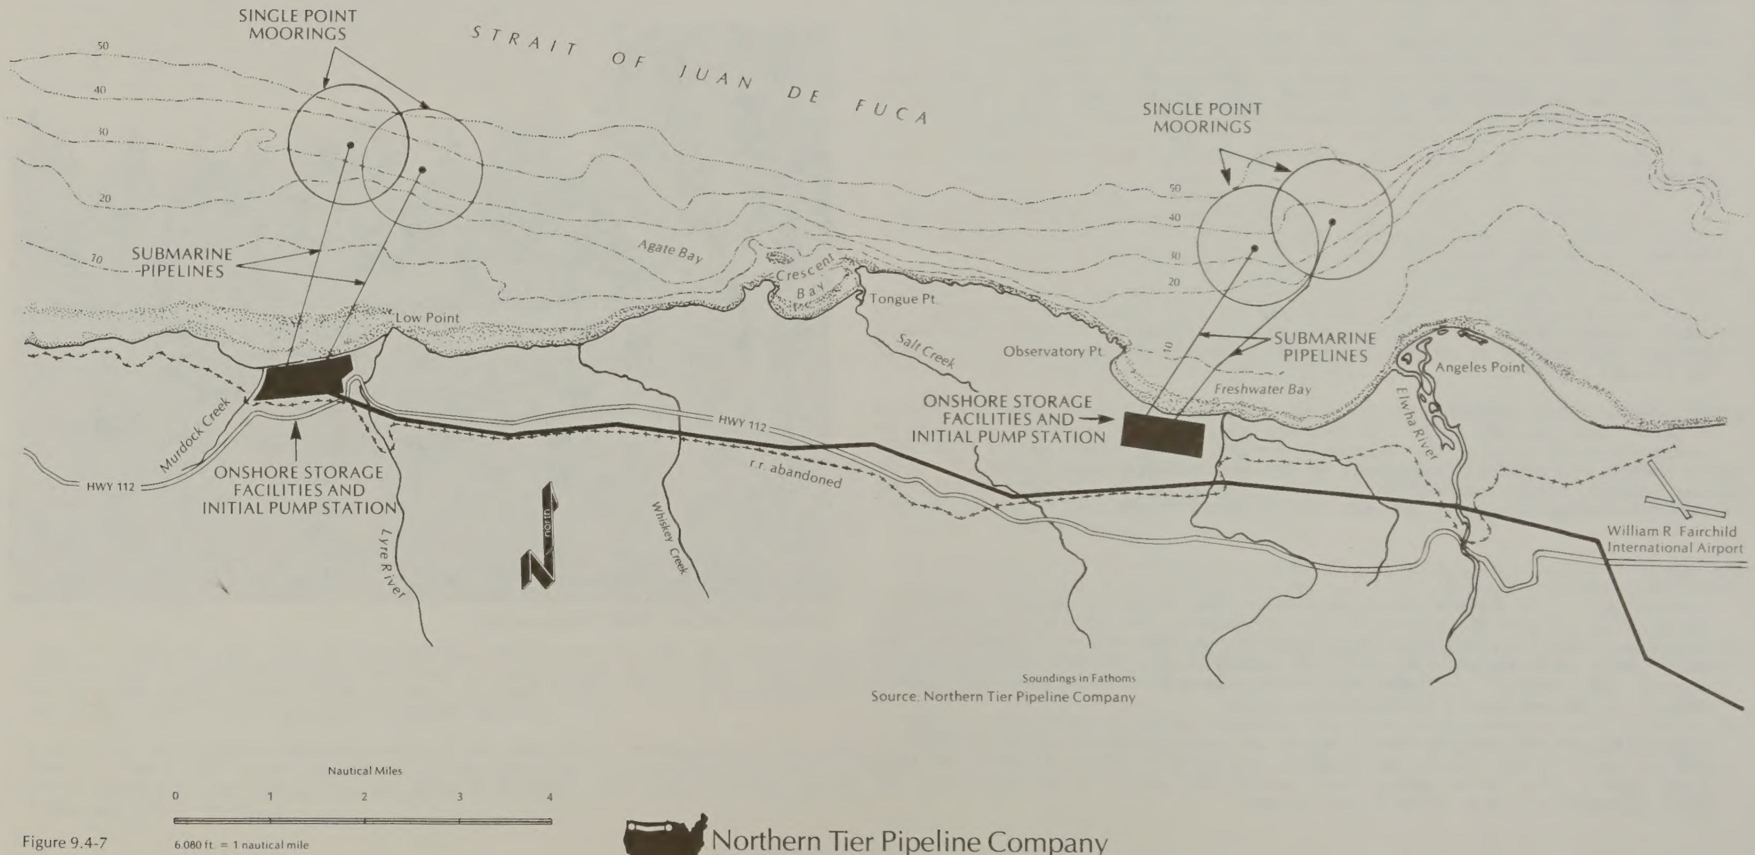
Freshwater Bay (figure 9.4-7), approximately 6 miles west of Port Angeles, would require two single point mooring (SPM) systems for offloading crude oil from tankers. Suitable water depths of 210 feet (35 fathoms) are only available about 10,000 feet offshore. The minimum water depth for the tankers swinging toward the shoreline would be 90 feet (15 fathoms). Onshore storage and pumping facilities would be located on land near Freshwater Bay. Seventeen miles of pipeline would be required to reach Green Point.

## Climate and Air Quality

No impacts on climate are anticipated for this alternative port site.

## LOW POINT PORT ALTERNATIVE

## FRESHWATER BAY PORT ALTERNATIVE



Soundings in Fathoms

Source: Northern Tier Pipeline Company

Figure 9.4-7

Northern Tier Pipeline Company

Freshwater Bay is located in rural surroundings and there are no large pollution sources in the immediate area. Some significant industrial pollution sources occur in Port Angeles, about 6 miles east of Freshwater Bay. There are no air quality data available for Freshwater Bay. However, background concentrations are expected to be relatively low due to the prevailing westerly winds which would tend to blow pollutants from Port Angeles away from the area.

A limited modeling study was performed by Science Applications, Inc. (SAI 1978). However, in the absence of meteorological data at Freshwater Bay, data for Port Angeles had to be used. Since these data may not be necessarily representative for Freshwater Bay, the modeling results would have to be interpreted with caution. This analysis assumes that the tankers would burn fuel with a sulfur content of 0.45 percent or less while operating in port, as proposed by the applicant. The highest annual average sulfur dioxide concentration for a 933,000 bpd throughput is 2.3 $ug/m^3$, which is 11 percent of the maximum allowable Class II increment. The highest concentration would occur about a mile east of the proposed SPM site. The modeling analysis indicated, however, potential violations of the Class I standards for sulfur dioxide in the Olympic National Park. A more comprehensive study would have to be made, after collecting on-site data, to determine whether the Class I standards would be met.

Calculated maximum 1-hour, 3-hour, and 24-hour average sulfur dioxide concentrations are well within the Federal and state ambient air quality standards, as well as the Class II incremental standards.

The maximum 24-hour average particulate concentration from the proposed alternative would be 0.8 $ug/m^3$ which is well within the Class II increment of 37 $ug/m^3$. The annual average particulate concentration would be negligible. The highest annual average concentration of nitrogen oxides is 1.2 $ug/m^3$, which is only 1.2 percent of the Federal standard.

No ozone modeling was performed for this alternative port site. However, impacts would be about the same as for the Port Angeles site. Little change in ozone concentrations would occur in the vicinity of the SPM. Ozone concentrations downwind of the onshore storage facilities might be increased slightly above background levels when conditions were favorable for ozone formation. However, it is not likely that this alternative project would cause any violation of the Federal ozone standard.

Olympic National Park Headquarters

## Noise

Construction of the onshore storage facilities would result in daytime noise levels ranging from 50 to 70 dBA at some of the residences in the vicinity of the construction site. This could be a source of annoyance to some of the residents as these noise levels would represent a significant intrusion upon the relatively noise-free existing environment. The relatively dense vegetation in the area would reduce some of the adverse impacts of construction noise.

Construction of the pipeline would result in noise levels of up to 65 dBA at a distance within 1,000 feet of the alignment and up to 50 dBA at distances of about 4,000 feet. These noise levels would be confined mostly to daytime hours, and would generally be sustained for 5 days or less.

During the operation phase, the primary noise would be from the electric onshore storage facility pumps. Noise levels would be generally audible at distances of less than 3,000 feet. The relatively dense vegetation in the area would reduce some of the noise levels.

## Topography and Geology

This alternate port site is characterized by gently northward sloping (4 to 5 percent) terrain, terminating in a moderately steep (up to 50 percent gradient), 50- to 75-foot high coastal bluff; the route segment to Green Point is characterized by relatively gentle terrain intersected by the Elwha River and a number of small streams. Although the proposed port site is located on terrain similar to Freshwater Bay, the need for an additional 17 miles of pipeline would result in a greater overall impact to topography--landform changes and minor drainage alterations.

Geologic materials found at Freshwater Bay and along the 17-mile pipeline to Green Point are similar to those found at the proposed port site and would consist primarily of Quaternary glacial debris. Consequently, impacts to the geologic materials would be similar and would consist of the excavation of large volumes of geologic material and some excavation-induced changes in the physical characteristics of the material (porosity, permeability, inherent rock strength, cementation, etc.). As the volume of material that would be removed at Freshwater Bay is unknown, a comparison of the magnitude of geologic impacts compared to Green Point cannot be made at present.

### Geologic Hazards

Geologic hazards that could be encountered at the port site and along the pipeline route would be seismicity, slope instability, and outburst flooding.

Freshwater Bay and the pipeline route to Port Angeles (Freshwater Bay pipeline mile 0 to 10) is located in an area of moderate to low seismic activity, corresponding to a Seismic Risk Zone 2 (moderate earthquake damage expected); the remainder of the route, to Green Point is located near the western margin of a moderately active seismic area corresponding to a Seismic Risk Zone 3 (maximum earthquake damage expected). Although this alternate port site and much of the pipeline would be within 10 miles of the possibly active Calawah Fault there is no evidence of apparent recent fault movement. Likewise, seismic activity is low at this port alternative. Although seismic activity could result in landslides along the unstable coastal bluffs, the overall anticipated seismic impacts should be less severe than at the proposed port site.

Like the proposed port site at Port Angeles, Freshwater Bay has slope instability problems and a landslide could cause severe damage to the oil terminal facilities. As the slope configuration and the geologic material is similar to the proposed port, anticipated impacts are expected to be about the same.

A potential for outburst flooding occurs at the Elwha River (Freshwater Bay pipeline mile 7), where some damage could occur to the pipeline. As no potential exists at the proposed port site for significant outburst flooding, this alternate would have a higher potential impact.

### Mineral Resources

No significant difference in impacts.

## Soils

Soils in the area of this alternate onshore storage facility are mostly gravelly sandy loams overlying glacial outwash material. The sandy and gravelly profile extends to great depths and is an excellent subgrade material. Rough broken lands rim the site on the north.

The nearly level to gently sloping soils would have a low susceptibility to erosion. Annual soil losses in the forest setting are in the range of 0.04 tons per acre. Removal of vegetation from the site would result in losses of 3 to 4 tons per acre per year. This would be reduced by 60 to 90 percent by use of diversion ditches and settling ponds. Revegetation would further reduce annual soil losses to less than 0.02 tons per acre.

These gravelly and sandy soils would be resistant to topsoil compaction by construction equipment. Loss of productivity would be less than 5 percent and would return to normal in two years.

Soil lost as fugitive dust would be in the range of 1.2 tons per acre for each month of construction, if 1/3 of the area would be undergoing construction at any one time.

Profile mixing and topsoil dilution with subsoils and parent material would be minimized by segregating and stockpiling the topsoils. Long term loss of productivity would amount to no more than 5 percent.

Contamination by oil spills would be restricted by retention dikes around storage tanks.

About 85 percent of the approximately 17-mile proposed pipeline route would traverse deep soils with loam and gravelly sandy loam textures and nearly level to rolling slopes. The remaining soils occur in narrow bands of rough broken land adjoining natural drainage channels.

Erosion susceptibility with vegetation removed would be in the range of 2.00 tons per acre per year soil loss and 0.11 tons per acre per year after complete revegetation occurs.

Low impacts from soil compaction during construction would be experienced by the sandy, gravelly soils. An estimated 3 percent of the productive capacity of the topsoil within the right-of-way would be lost for 2 to 3 years.

Topsoil segregation or double trenching techniques would minimize profile mixing and topsoil dilution. Long term loss of fertility would be less than 5 percent.

## Aquatic Resources

### Physical Components

Fourteen rivers and creeks would be crossed by the proposed alignment of the Freshwater Bay alternative. The Elwha River and Morse and Siebert Creeks are the largest streams that would be crossed between the proposed tank farm site and the prime pipeline alignment south of Green Point. Seasonal variation of stream discharge generally occurs, with high flow periods in late summer and again in late winter. Flow is generally unregulated with the exception of the Elwha River which has several dams upstream of the proposed crossing. Water quality of all streams along the proposed alignment is Class A (excellent) or Class AA (extraordinary) by Washington State Water Quality Standards (WAC 173-201).

Several impacts to surface and ground water would result from construction and operation of the pipeline and onshore storage facility. Short-term increases in turbidity would occur at and downstream of the river crossings during pipeline construction. Ground water in some of the valley areas along the alignment is encountered within 5 feet of the land surface. In these regions dewatering of the trench during construction would impact the water table level and ground water movement. Short-term sediment impact to shallow ground water regions could be anticipated from percolation of sediment laden waters. Hydrostatic test water would be withdrawn from one or several streams along the proposed route for testing of the storage tanks and pipeline. A decrease of stream discharge would occur during the withdrawal period.

No major impact would result from normal operation, however, in the event of a pipe rupture, oil could enter surface and ground water. Most stream crossings would be within 3 miles of the Strait so spilled oil would probably enter the marine environment before containment. Water quality degradation would occur for perhaps 1 year following the spill. Refer to chapter 3, for a more detailed discussion of impacts.

### Biological Components

The pipeline route between Freshwater Bay and the proposed route near Green Point would cross eight streams which support salmon and searun trout populations. Resident trout also occur in these streams. The most important streams are the Elwha River and Morse Creek. Significant spawning habitat for salmon and trout occur in the Elwha River in the vicinity of the crossing area.

Reductions to salmon and trout populations would occur as a result of spawning gravel sedimentation. Sediment would come from instream trenching activities during construction and from streambank erosion during project operation. Most of the sediment from instream trenching would be washed out of the spawning gravel during the first period of high flow, but sediment arising from streambank erosion would continue for several years until complete revegetation occurs. The greatest reductions to salmon and trout populations would occur during construction and for the first few years of project operation. Several spawning cycles would be required for these populations to recover to preproject levels. Reduced trout populations should recover in several years while salmon might take 20 years to fully recover. The initial population reductions during construction would probably not be noticed in the ocean sport, commercial, or Indian fisheries, but might be noticed in the river fisheries if large numbers of one year-classes were eliminated. In subsequent years during project operation, population reductions would probably be within the normal range of population fluctuations and would not be noticed.

Reductions to fish populations would occur if an oil spill occurred during project operation. Trout and salmon populations would be reduced for several miles downstream from the spill site. Several spawning cycles would be required for reduced populations to recover to prespill levels; several years for trout and up to 20 years for salmon. Population reductions would probably not be noticed in the ocean sport, commercial, or Indian fisheries, but might be noticed in the river fisheries, particularly following a large spill.

## Marine Resources

### Physical Components

A description of the physical oceanographic conditions in the vicinity of Freshwater Bay may be found in chapter 2.

Estimated frequencies for various existing, incremental, and combined oil spill risks, and explosion and fire risks are given in table 9.4-7. The at berth risk for a single point mooring at Freshwater Bay is about one spill every 0.28 years for the initial throughput and one spill about every 0.21 years for ultimate throughout.

Oil spill trajectories for hypothetical oil spills in March and September at the Freshwater Bay are shown in Map Addendum. The March simulations included a 10 cm/sec estuarine flow and the September trajectories were calculated with a 30 cm/sec estuarine flow in the model. Oil spills during March or September oceanographic and meteorological conditions would initially impact a region between Tongue Point and Ediz Hook. This would involve about 11 nautical miles of shoreline (Stewart 1978).

Expressions of probability are useful indicators of future events, but caution must be taken to avoid misinterpretation of these estimated values. "One spill every 'X' years" expresses a calculated rate and does not indicate when the spill may occur. Also, the estimate will remain valid only if conditions do not deviate significantly from historical patterns.

## TABLE 9.4-7 ESTIMATED FREQUENCIES OF VARIOUS RISKS FOR OIL TRANSSHIPMENT FROM FRESHWATER BAY TO GREEN POINT

| Risk Involved | Estimated Existing Risks 1/ | Estimated Incremental Risks | | Estimated Combined Risks | | Estimated Incremental Risk for Onshore Pipeline | |
|---|---|---|---|---|---|---|---|
| | One Casualty Every: | 709,000 bbls/day One Casualty Every: | 933,000 bbls/day | 709,000 bbls/day One Casualty Every: | 933,000 bbls/day | 709,000 bbls/day One Casualty Every: | 933,000 bbls/day |
| Oil Spill: | | | | | | | |
| In-Transit (≥2.4 bbls) | 1.2 years (0.7-4.1) | 4.6 years (2.7-16) | 3.5 years (2.1-12) | 0.95 years (0.56-3.31) | 0.90 years (0.52-3.09) | | |
| At Single Point Mooring (≥2.4 bbls) | | 0.28 years | 0.21 years | | | | |
| Bunker Barge (≥2.4 bbls) | 0.27 years (0.17-0.58) | 1.56 years (1.00-3.40) | 1.18 years (0.76-2.58) | | | | |
| Tank Farm 2/ (≥2.4 bbls) | 0.19 years (0.16-0.24) | 0.96 years (0.78-1.3) | 0.59 years (0.48-0.76) | | | | |
| Pipeline 3/ (≥2.4 bbls) | 1.19 years | | | | | 2.3 years (1.1-XX) | |
| Explosion: | | | | | | | |
| In-Transit | ~31 years | ~120 years | ~93 years | ~25 years | ~23 years | | |
| Harbor Area | ~37 years | ~63 years | ~49 years | ~24 years | ~21 years | | |

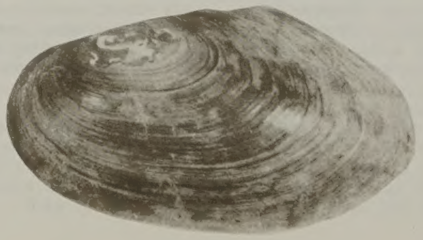
| Tank Farm (≥$1,000) | | ~64 years (42-133) | | | | | |
| Pipeline Station (≥$1,000) | | ~66 years (50-99) | | | | | |

Source: OIW 1978a,b,c, 1979a

1/ The ranges shown in parenthesis for each throughput are estimates of the 95 percent confidence limits.

2/ The estimated existing risk range shown in parenthesis is an estimate of the 97 percent confidence limit.

3/ The upper confidence limits are unpredictable and are indicated by "XX".



## Biological Components

Habitats in Freshwater Bay consist of sandy beaches and sand and rocks offshore. Eelgrass beds extend from Observatory Point on the west to about Coville Creek. Resources consist of intertidal clams, crabs, sport salmon fishing, and commercial otter trawling within the bay and salmon purse seine fishing off Angeles Point. The western part, particularly inside the eelgrass beds, is a major waterfowl area. The location of these resources within Freshwater Bay and in the adjacent Strait of Juan de Fuca are found in Map Addendum.

No significant impacts to the marine environment should occur as a result of construction of single point moorings off Freshwater Bay.

Operational impacts resulting from in-transit or from at-berth single point mooring ruptures of transfer hoses, and of exposed submarine pipelines, and chronic oil spills would degrade the water quality in Freshwater Bay and in the Strait and affect marine resources within the area.

Resources impacted would be intertidal clams and fishes of commercial and sport value in and adjacent to the bay, and the otter habitat and Pacific halibut spawning grounds in Crescent Bay. Waterfowl mortality would also be expected in Freshwater Bay. Specific details on oil spill impacts can be found in chapter 3.

No marine resource impact would occur in removing the single point moorings at Freshwater Bay.

### Terrestrial Vegetation

In considering potential impacts resulting from storage facility and pipeline construction and operation, it was assumed that 140 acres of forest land on the storage area would be cleared, that 9 miles of the 17-mile pipeline corridor is forested and that Bonneville Power Administration right-of-way is paralleled along the entire alternate pipeline route.

The pipeline and storage facility area is within the cedar-hemlock-Douglas-fir forest ecoregion. Western red cedar, western hemlock, Douglas-fir, and red alder are dominant components of these forest lands. About 204 acres of dominant forest vegetation, assumed to average 1,400 board feet per acre, would be lost from timber production for at least 25 years. This would be the most substantial impact on vegetation resulting from implementation of this alternative.

No endangered or threatened plant species are known to occur within the storage area or pipeline corridor.

### Terrestrial Wildlife

Assuming the wildlife habitat is similar to the Low Point and Green Point alternatives, the area may have high potential for bald eagle and peregrine falcon habitat. No nests are known and sightings are not confirmed. Construction of the pipeline would change 200 acres of forest wildlife habitat to open type.

### Cultural Resources

The proposed port alternative at Freshwater Bay and the pipeline segment connecting the port site with the primary pipeline route would not affect any currently known cultural resource sites. There is high potential for discovery of sites, especially along the shoreline near the mouth of the Elwha River where pipelines from the monobouys would come on land. Impacts on any sites would be the same as those discussed in chapter 3.

### Visual Resources

Freshwater Bay would have two single point moorings (SPM) located 4/5 of a mile, to a little over a mile from shore.

Each SPM would have a submarine line to an onshore tank farm. As this confluence of two submarine pipelines emerged from the water and ascended to the tank farm 125 feet above, a wedge-shaped notch, similar to that at Green Point would be excavated. This would be visually offensive to viewers from boats in the Strait.

The tank farm would require the clearing of 140 acres of forestland and could have high visual impact when viewed from the Strait and/or from local residences.

A few miles of new pipeline right-of-way is anticipated, from the tank farm south, where it turns east and would parallel and possibly partially superimpose the BPA corridor for about 17 miles where it ties into the prime route from Green Point south.

Construction impacts may be high, especially through populated areas, persisting as a low for the life of the project. Moderate impact could be caused by the crossings at State Highway 112 and U.S. 101.

### Land Use

Existing land uses near the onshore storage facility and along the proposed pipeline route consist primarily of forest land with interspersed pasture land and rural residential use. In terms of land use, most of the impact would be to forest lands as previously described (see Terrestrial Vegetation).

The onshore storage facility would be located in an area of Clallam County that is not zoned. Planned land use for the onshore storage site and pipeline route west of Port Angeles is designated "potential living area." A new preliminary land use plan that has not yet been adopted designates these areas for residential use. About 1 mile of the pipeline route has been zoned by the city of Port Angeles for residential and public use. East of Port Angeles the pipeline route traverses areas zoned by Clallam County for forest and agricultural uses. Although the onshore storage site does not conflict with zoning (in its absence), it does conflict with the planned residential use. The project might not be consistent with the Clallam County Shoreline Master Program.

Areas with special management concerns that would be affected include the Lower Elwha Indian Reservation located on Angeles Point, 2 to 3 miles east of the SPM sites and the onshore storage facility. The pipeline route would traverse 1/4 mile of Olympic National Park, requiring disturbance of about 3 acres of forest land within the park.

### Transportation and Utility Networks

The Freshwater Bay SPM site would be located adjacent to the precautionary area at buoy "JA," with the SPM buoys situated obliquely to the Strait rather than parallel. It might therefore present some inconvenience and hazard to smaller tugs and their tows operating close to the shoreline. The inbound traffic lane would be about 7,000 feet from the closest mooring, and the channel widening at Freshwater Bay would appear to provide sufficient room for queuing tankers to prevent any significant hazard to larger vessels using the traffic lanes.

State Highway 112, a 2-lane highway, provides access to the Freshwater Bay area. Construction traffic would significantly lower service levels on State Highway 112 from Port Angeles west to Freshwater Bay during the first year of construction.

Electric power requirements for this alternative would be similar to those of the proposed action and would cause essentially the same impacts as the proposed action.

### Recreation

No significant impacts to known recreational activities are anticipated as a result of normal construction, operation, or abandonment activities associated with the SPM, onshore facilities, or connecting pipeline system. The crossing area of the Elwha River is managed for scenic and recreational values according to the Shoreline Management Act of 1971.

Oil spills at sea would impact local offshore bottom and salmon fishing areas, steelhead fishing on the Elwha River, as well as several public beaches, parks, and shellfish collecting areas. See Map Addendum for locations of marine recreation areas.

Preliminary oil-spill risk analysis indicates that if a tanker collision occurred off the SPM in March, oil would impact sport salmon fishing in the Crescent and Freshwater Bay areas, and from Port Angeles to the Dungeness Spit area. Shellfish collection in Crescent and Freshwater Bays as well as the Dungeness Spit area could be lost. Loss of the shellfish beds, which could take 4 to 10 years to return to productivity, would diminish recreational attractiveness of the Dungeness Spit. Loss of use of, and impacts relating to oil fouling of, parks and marinas between the Crescent Bay and the Dungeness Spit areas would severely impact marine recreationists for the season. Impacts to the Port Angeles areas are discussed in chapter 3. Impacts from a tanker incident off the SPM occurring in September would be less severe. Impacts to recreation would be experienced from roughly Pillar Point to Freshwater Bay.

In general, impacts would be less along this route alternate as compared to the proposed route as a result of avoiding the Port Angeles metropolitan area and harbor.

### Social and Economic Conditions

This section considers both the Freshwater Bay alternative and the pipeline section which extends from Green Point to the Clallam County border, since the impacts from both would affect the county simultaneously.

The Freshwater Bay alternative and the pipeline would bring a peak population increase of 1,160 during construction and 202 during operation. The increase during construction represents a 2.6 percent increase over the projected 1980 population for Clallam County. Most of the population would reside in Clallam County. The additional 17 miles of pipeline would require a larger construction force than for the NTPC proposed route.

Assessed valuation of the alternative would be $89,300,000 and with the additional 17 miles of pipeline west of Green Point it would be $97,200,000. Property taxes would amount to $1,385,000 for the Freshwater Bay alternative, and $1,505,000 with the additional pipeline.

Impacts on community services would be similar to those created by the proposal submitted by NTPC. A detailed discussion is found in chapter 3 of this report. During construction housing would be insufficient to accommodate the population increase, schools would be slightly strained, and increased demands would be placed on police and fire personnel. The fire district which serves the Freshwater Bay area is rated 9 on Washington's 10-point insurance rating system, and would not be equipped to handle project-related emergencies during construction and operation.

Changes in the quality of life in Port Angeles would be less significant than with the proposed port at Port Angeles, except in the event of a major oil spill.

The Lower Elwha Indian Reservation would be substantially impacted by this alternative. The Indians rely heavily on Freshwater Bay for fishing which supports their economy and preserves their traditional way of life. Construction activity, tanker traffic, and possible oil spills would significantly disrupt these activities.

## LOW POINT

### Description

From a survey of six port sites located west of Port Angeles, NTPC selected Low Point as their primary alternative in the siting application to Washington Energy Facility Site Evaluation Council, 1978. The tanker unloading facilities would be two SPM's located north of Low Point in a 210 foot (35 fathoms) water depth in the Strait of Juan de Fuca. The tanker swinging radii toward shore would be about 4000 feet which would be at a 90 foot (15 fathoms) water depth. Two submarine pipelines, approximately 2.6 miles in length, would be constructed from the SPMs to the shoreline and then up to the onshore storage facilities located on about 294 acres (figure 9.4-7).

The pipeline system from the Low Point alternative site to the proposed pipeline near Green Point would require one additional pump station and about 28 miles of additional pipeline. This route would cross agricultural and forest lands and would parallel about 10 miles of power transmission right-of-way to the connection with the proposed NTPC pipeline corridor from Green Point.

### Climate and Air Quality

No impacts on climate are anticipated for this alternative port site.

Low Point is located in rural surroundings and there are no large pollution sources in the immediate area. Some significant industrial pollution sources are found in Port Angeles, about 20 miles east of Low Point. There are no air quality data available for Low Point. However, background concentrations are expected to be low, as there is little influence from the Port Angeles pollution sources.

A limited modeling study was performed by Science Applications, Inc. (SAI 1978). However, in the absence of meteorological data at Low Point, meteorological data for Port Angeles had to be used. Since these data may not necessarily be representative for the site, the modeling results would have to be interpreted with caution. This analysis assumes that the tankers would burn fuel with a sulfur content of 0.45 percent or less while operating in port, as proposed by the applicant.

Calculated maximum 1-hour, 3-hour, and 24-hour average sulfur dioxide concentrations are well within the federal and state air quality standards. The highest annual average sulfur dioxide concentration for a 933,000 bpd throughput is 2.3 ug/m$^3$, which is 11 percent of the maximum allowable Class II increment. The highest concentration would occur about a mile east of the proposed SPM site. The modeling analysis indicated, however, potential violations of the Class I standards for sulfur dioxide in the Olympic National Park. A more comprehensive study would have to be made after collecting some on-site data, to determine whether the Class I standards would be met.

The maximum 24-hour average particulate concentration from this alternative proposal would be 0.8 ug/m$^3$ which is well within the Class II increment of 37 ug/m$^3$. The annual average particulate concentration would be negligible.

The highest annual average concentration of nitrogen oxides would be 1.2 ug/m$^3$ which is 12 percent of the Federal standard.

No ozone modeling was performed for this alternative port site. However, impacts would be about the same as for the Port Angeles site. Little change in ozone concentrations would occur in the vicinity of the SPM. Ozone concentrations downwind of the onshore storage facilities might be increased by about 10 to 20 percent above background levels when conditions were favorable for ozone formation. However, it is not likely that the project would cause any violation of the Federal ozone standards.

### Noise

During the construction of the onshore storage facilities, noise levels up to 70 dBA would occur in areas adjacent to the construction site. Noise levels could adversely affect recreational activities at the nearby Lyre River Campground.

Construction of the pipeline would cause noise levels of up to 65 dBA at a distance within 1,000 feet of the alignment and up to 50 dBA at distances of about 4,000 feet.

These noise levels would be mostly confined to daytime hours, and would be sustained for 5 days or less.

During the operation phase the primary noise source would be the electric onshore storage facilities pumps. Noise would generally be audible at distances of less than 3,000 feet. The relatively dense vegetation that exists in the area would reduce some of the noise levels.

## Topography and Geology

This alternate port site is characterized by gently sloping terrain (5° to 7° to the north), terminating in a relatively steep coastal bluff 100- to 150-feet high. The 28-mile pipeline route segment is characterized by relatively gentle terrain, intersected by the Elwha River and numerous small streams. Seventeen miles of this route, from Freshwater Bay to Green Point cover essentially the same terrain as the Freshwater Bay alternative. While construction for this port alternative would result in fewer acres disturbed than at the proposed port site (140 acres as opposed to 242), the need for 28 miles of additional pipeline and additional 336 acres (12 acres per mile) disturbed would result in a greater topographic impact for this alternative than for the proposed port.

Surficial geologic materials found at Low Point and along the 28-mile route to Green Point are similar to those found at the proposed port site consisting primarily of Quaternary glacial debris. Consequently, impacts to the gologic materials would be similar, consisting of the excavation of large volumes of geologic material and some excavation-induced changes in the physical characteristics of the material (porosity, permeability, erosion potential, etc.). As the anticipated volume of material that would be excavated at Low Point is unknown, a quantifiable comparison with Green Point as to the magnitude of impacts cannot be made at present.

### Geologic Hazards

Low Point and the pipeline route to Port Angeles (Low Point pipeline mile 20) is located in an area of moderate to low seismic activity corresponding to a Seismic Risk Zone 2 (moderate earthquake damage expected); the remainder of the route to Green Point, is located near the western margin of a moderately active seismic area corresponding to a Seismic Risk Zone 3 (maximum earthquake damage expected). Like the Freshwater Bay route alternative, this route would come within 10 miles of the possibly active Calawah Fault; however, there is no evidence of apparent recent fault movement. In like measure, seismic activity is lower at this port alternative than at the proposed port site. Although seismic activity could result in landslides along the potentially unstable coastal bluffs, the overall anticipated seismic impacts should be lower than at the proposed port site.

Although no evidence of significant landsliding is apparent at Low Point, there is some evidence of slope instability west of the port site (NTPC 1978). Consequently, there is a potential for landsliding in the area; there is no evidence of slope instability along the pipeline route. As little detailed study has been conducted at Low Point, it is not presently possible to compare slope instability impacts at Low Point with Green Point.

A potential for outburst flooding occurs at the Elwha River (Low Point pipeline mile 18), where some damage could occur to the pipeline. As no potential exits at the proposed site for significant outburst flooding, the anticipated impacts would be greater along this alternate route segment.

### Mineral Resources

No significant difference in impacts has been identified.

## Soils

The dominant soil at this alternative proposed onshore storage facility is Agnew silty clay loam. This is a deep, somewhat poorly drained glacial till soil with nearly level surface. Perched water tables are common. Impacts from erosion during construction would be low because of the low surface gradients and erosion control measures such as settling ponds, diversionary channels, and protective mulch. Normal annual soil loss would be approximately 0.01 tons per acre as compared to 0.66 tons per acre during construction. Revegetation after construction would reduce losses to about 0.06 tons per acre.

The silty clay loam surface soils would be highly susceptible to compaction by construction traffic and would lose an estimated 10 percent of productive potential for a period of about 2 years. Adverse impacts from profile mixing would be low because of topsoil segregation and minimal need for cut and fill operations.

Soils of the proposed route consist of about 58 percent Elwha loams, 24 percent Clallam loams, 7 percent Everett gravelly and sandy loams, 7 percent rough broken lands, and 4 percent miscellaneous soils. Slopes would vary from nearby level to rolling. These are deep gravelly soils on glacial uplands.

Erosion susceptibility would be approximately 0.20 tons per acre per year loss after complete revegetation.

Adverse impacts from soil compaction during construction would be low. The gravelly loam soils would lose an estimated 5 percent of productivity and would return to normal in 2 to 3 years. Profile mixing and topsoil dilution would be minimal providing topsoil segregation procedures are followed.

## Aquatic Resources

### Physical Components

Twenty-four rivers and creeks would be crossed by the proposed alignment of the Low Point alternative. The Lyre and Elwha Rivers, and Morse and Siebert Creeks are the largest streams that would be crossed by the proposed pipeline between the proposed tank farm site and the junction with the NTPC proposed pipeline south of Green Point. Seasonal variation of stream discharge generally occurs, with high flow periods in late fall or early winter, and low flow periods in late summer and again in late winter. Flow is unregulated with the exception of the Elwha River which has several dams upstream of the proposed alignment. Water quality of these streams is Class A (excellent) or Class AA (extraordinary) by Washington State Water Quality Standards (WAC 173-201).

Several impacts to surface and ground water would result from construction and operation of the pipeline and onshore storage facility. Short-term increases of sediment load would be anticipated at and downstream of the river crossings during pipeline construction. Increased turbidity and siltation on the Lyre River could result from construction of the onshore storage facility. Ground water in some of the valley areas along the alignment would be encountered within 5 feet of the land surface. In these regions dewatering of the trench during construction would impact the water table level and ground water movement. Short-term sediment impact to shallow ground water regions could be anticipated from percolation of sediment laden waters. Hydrostatic test water would be withdrawn from one or several streams along the proposed route for testing of the storage tanks and pipeline. A decrease of stream discharge would occur during the withdrawal period. No major impact would result from normal operation, However, in the event of a pipe rupture oil could enter surface water and groundwater. Most stream crossings would be within 3 miles of the Strait of Juan de Fuca, so spilled oil would probably enter the marine environment as well. Water quality degradation would occur for at least 1 year following the spill. Refer to chapter 3 for a more detailed discussson of impacts.

### Biological Components

The pipeline route between Low Point and the proposed route near Green Point would cross 16 streams which support salmon and searun trout populations. Resident trout also occur in these streams. The most important streams are the Lyre and Elwha Rivers, and Suzie, Nelson, Salt, and Morse Creeks.

Significant spawning habitat for salmon and trout occurs on the Elwha River downstream from the crossing area.

Reductions to salmon and trout populations would occur as a result of spawning gravel sedimentation. Sediment would come from instream trenching activities during construction and from streambank erosion during project operation. Most of the sediment from instream trenching would be washed out of the spawning gravel during the first period of high flow, but sediment arising from streambank erosion would continue for several years until complete revegetation occurs. The greatest reductions to salmon and trout populations would occur during construction and for the first few years of project operation. Several spawning cycles would be required for these populations to recover to preproject levels.

Reduced trout population should recover in several years while salmon may take 20 years to fully recover. The initial population reduction during construction would probably not be noticed in the ocean sport, commercial, or Indian fisheries, but might be noticed in the river fisheries if large numbers of 1 year-class are eliminated. In subsequent years during project operation, population reductions would probably be within the normal range of population fluctuations and consequently would not be noticed.

Reductions to fish populations would occur if an oil spill occurs during project operation. Trout and salmon populations would be reduced for several miles downstream from the spill site. Several spawning cycles would be required for reduced populations to recover to prespill levels; several years for trout and up to 20 years for salmon. Population reductions would probably not be noticed in the ocean sport, commercial, or Indian fisheries, but might be noticed in the river fisheries, particularly following a large spill. The chance of an oil spill occurring at a stream crossing would be the same as with the proposed route.

See chapter 3 for a more detailed analysis of impacts.

## Marine Resources

### Physical Components

Physical oceanographic conditions at Low Point and in the adjacent Strait of Juan de Fuca are described in chapter 2.

Estimated existing, incremental, and combined frequencies for various oil spill risks and explosion and fire risks are presented in table 9.4-8. The estimated risks for the single point moorings are one spill about every 0.28 years for 709,000 barrels per day throughput and one spill about every 0.21 years for 933,000 barrels per day throughput. The estimated pipeline spill risk, for about 106 onshore miles and about 20 offshore miles of pipeline to Green Point, is one spill every 4.0 years for both throughputs. Detailed discussion of risk analyses can be found in chapter 3.

Oil spill trajectories off Low Point were computer simulated in March and September. Estuarine flows of 10 cm/sec for March and 30 cm/sec for September were included in the computer model. These trajectories are shown in the Map Addendum. For March oil spills the most likely initial impact zone would be between Deep Creek and Crescent Rock. But, due to a frequently observed cross channel current, it was also inferred that Parsons Point to Cape Calver and the Sooke Basin, Canada, could also be initial impact zones for a spill off Low Point. Oil spills during September could initially impact the coastline somewhere between Pillar Point and Crescent Rock.
Because of channel cross currents, Parsons Point to Cape Calver and the Sooke Basin could also be initial impact zones. The most likely initial impact zones and shoreline miles in each zone are given in table 9.4-9.

Expressions of probability are useful indicators of future events, but caution must be taken to avoid misinterpretation of these estimated values. "One spill every 'X' years expresses a calculated rate and does not indicate when the spill may occur. Also, the estimate will remain valid only if conditions do not deviate significantly from historical patterns.

TABLE 9.4-8 ESTIMATED FREQUENCIES OF VARIOUS RISKS FOR OIL TRANSSHIPMENT FROM LOWPOINT TO GREEN POINT

| Risk Involved | Estimated Existing Risks 1/ | Estimated Incremental Risks | | Estimated Combined Risks | |
|---|---|---|---|---|---|
| | One Casualty Every: | 709,000 bbls/day One Casualty Every: | 933,000 bbls/day | 709,000 bbls/day One Casualty Every: | 933,000 bbls/day |
| Oil Spill: | | | | | |
| In-Transit (≥2.4 bbls) | 1.2 years (0.7-4.1) | 5.6 years (3.3-19) | 4.3 years (2.5-15) | 0.99 years (0.58-3.42) | 0.94 years (0.55-3.26) |
| At Single Point Mooring (≥3.6 bbls) | | 0.28 years | 0.21 years | | |
| Bunker Barge (≥2.4 bbls) | 0.27 years (0.17-0.58) | 1.56 years (1.00-3.40) | 1.18 years (0.76-2.58) | | |
| Tank Farm 2/ (≥2.4 bbls) | 0.19 years (0.16-0.24) | 0.96 years (0.78-1.3) | 0.59 years (0.48-0.76) | | |
| Pipeline 3/ (≥2.4 bbls) | 1.19 years (0.57-XX) | 4.0 years (1.9-XX) | | | |
| Explosion: | | | | | |
| In-Transit | ~31 years | ~150 years | ~110 years | ~29 years | ~24 years |
| Harbor Area | ~37 years | ~63 years | ~49 years | ~24 years | ~21 years |
| Fire: | | | | | |
| In-Transit | ~35 years | ~170 years | ~130 years | ~29 years | ~27 years |
| Harbor Area | ~15 years | | | | |
| Fire and Explosion | | | | | |
| Tank Farm (≥$1,000) | | ~64 years (42-133) | | | |
| Pipeline Station (≥$1,000) | | ~66 years (50-99) | | | |

## Biological Components

The marine habitats at and offshore of Low Point are sandy beach and rocky, mixed subtidal strata. Marine resources in the area are crabs, commercial gill net, purse seine and otter trawl fisheries, and sports fisheries. General distribution of these resources are shown in the Map Addendum.

Halibut spawning grounds are off Crescent Bay, Port Angeles, Green Point, and Dungeness spit. Harbor seals haul out at Low Point and in Dungeness Bay, and river otter are found in Crescent Bay. Waterfowl nesting and/or roosting areas are concentrated off Green Point, on Dungeness Spit, and southeast of Dungeness Bay to Sequim Bay.

No construction impacts are anticipated during placement of the single point moorings and associated submarine pipelines at Low Point.

During the operation phase small but frequent oil spills from in-transit casualties from tankers at-berth at the single point moorings, and from transfer hoses and submarine pipeline ruptures would degrade the water quality at Low Point and in the strait.

Extensive water quality degradation in the Strait of Juan de Fuca could occur as a result of a large in-transit or at-berth oil spill at Low Point. A large spill would affect Canadian and United States commercial and sports fisheries and the shrimp, crab, clam, and oyster industries. High mortality of diving birds southeast of Dungeness Spit and off Green Point could occur. The harbor seal hauling out area at Low Point and the river otter habitat in Crescent Bay could be severely oiled. Heavy mortality to herring roe could occur and the loss of one year class of herring could have an indirect impact upon salmon, who would have normally fed upon that year class.

### Terrestrial Vegetation

The onshore storage facility and the associated pipeline segment for this port alternative are within the cedar-hemlock-Douglas-fir forest ecoregion. Species for this region, which are dominant at Low Point, include Douglas-fir, western hemlock, and western red cedar, red alder, and Sitka spruce are also important tree components at Low Point.

Construction of the storage facility would require clearing of 140 acres dominated by Douglas-fir, western red cedar and red alder (Energy Facility Site Evaluation Council application by Northern Tier Pipeline Company 1978). Timber volume that would be lost is estimated to be about 10 thousand board feet per acre. This area would not be available for timber production for at least 25 years.

Approximately 22 miles of the 28-mile pipeline corridor is forest land dominated by western red cedar, Douglas-fir, and red alder. The most substantial vegetation impact would result from clearing of this approximately 230 acres of forest. This forest land supports about 14 thousand board feet per acre of timber. Timber production would be lost on most of this acreage for at least 25 years.

No threatened or endangered plant species are known to occur within the storage facility area or the pipeline corridor.

### Terrestrial Wildlife

Impacts to wildlife would include modification of 140 acres of habitat, short- and long-term displacement of animals, death of nonmobile species, increased stress, and changes in species composition.

An active bald eagle nest is within 5 miles of the proposed onshore facilities. Bald eagles scavenge marine habitats including sandy and rock beaches and may hunt along the Low Point shoreline. Long-term effects from the loss of an occasional feeding ground and increased disturbance could be the disruption of a breeding season in a species with naturally low reproductive rate. Bald eagles breed only in years when food and other conditions are optimal.

The occurrence of peregrine falcons in the region has been documented (Funkhouser 1978), but their presence on the site would probably be limited to occasional use of trees near the bluffs as hunting perches.

The Peale's peregrine falcon may occasionally use the this alternative onshore storage facilities site. This raptor prefers open country including beaches, sand spits (such as Dungeness Spit), and marshes (Eaton 1975).

The bald eagle, peregrine falcon, and other wildlife requiring undisturbed habitat, could suffer short-term effects during construction of onshore storage facilities.

The pipeline would cross 22 miles of coniferous forest and eliminate 230 acres of forest habitat. The change in habitat would adversely affect some species while benefiting others.

Ruffed grouse are present in relatively high numbers on the site and may average 2.3 birds per square mile in spring. Their preferred habitat is abundant in the area. Long-term impact would include reduction and permanent alteration of shrub habitat at the storage facility site, whereas, short-term shrub disturbance would probably occur from corridor maintenance.

Oil spills could result in toxic effects to wildlife and destruction of habitat.

### Cultural Resources

The port at Low Point and the pipeline segment connecting the port and onshore storage facility site to the proposed pipeline route would potentially affect the cultural resource sites listed below. There is high potential for discovery of additional archaeological and historical sites along the shoreline of the Strait of Juan de Fuca and at the crossings of the Elwha River and several smaller stream valleys. The currently known sites, all in Clallam County, are:

TABLE 9.4-10 CULTURAL RESOURCE SITE, LOW POINT ALTERNATIVE

| Site Name | Site Type | Location |
|---|---|---|
| 45CA 10 | Campsite and shell midden | Onshore storate site |
| 45CA 11 | Campsite and shell midden | Onshore storage site |
| Ocean View Cemetery | Historic | In Port Angeles |
| Lincoln Park | Historic | In Port Angeles |
| Beaumont Cabin | Historic | In Port Angeles |
| Clallam County Courthouse | Historic | In Port Angeles |
| Congregational Church | Historic | In Port Angeles |
| Masonic Temple | Historic | In Port Angeles |
| Olympic Hotel | Historic | In Port Angeles |
| St. Andrews Episcopal Church | Historic | In Port Angeles |
| Mt. Angeles Cemetery | Historic | In Port Anglees |

Potential impacts to these sites would be the same as those discussed in chapter 3.

### Visual Resources

Low Point would have two single point moorings located about 10,000 feet from shore. Each single point mooring would have a submarine line, that would emerge from the water at the shoreline and traverse the 50-foot bluff as it ascended to the tank farm. The tank farm would be located southwest of the Low Point single point moorings and would require the clearing of approximately 150 acres of forest land on a 5 to 7 percent slope. This slope could necessitate a multilevel tank farm site design and create an adverse visual impact when observed from the strait, shoreline, or when visiting the site. The notch cut for the pipeline through the bluff should have an impact similar to the proposed cut at Green Point. See section 3.1.11 for impacts.

Construction of the pipeline in a southerly direction, where it would join and parallel the Bonneville Power Administration existing corridor in an easterly direction, would require the clearing of a 90-foot right-of-way through mixed forest land.

Impacts through this section should be moderate to high, for the life of the project.

### Land Use

Existing land uses near the onshore storage facility and along the proposed pipeline route consist primarily of forest land with interspersed pastureland and rural residential use. Construction activity for both the storage facility and the pipeline would directly impact approximately 350 additional acres within Clallam County with 260 acres occupied by permanent pipeline right-of-way and the additional pump station.

The onshore storage facility would be located in an area that is unzoned. The Clallam County Comprehensive Plan designates the area as potential living area, and the preliminary plan (not yet adopted) designates the area for residential use. The pipeline route traverses areas zoned for forest and agricultural use by Clallam County, and about 1 mile passes through areas zoned by Port Angeles for residential and public uses. As at Green Point construction of the submarine pipeline to the onshore storage site might not be consistent with the Clallam County Shoreline Master Program. In terms of the amount of land converted to project use the impact of the Low Point alternative would not be significant.

### Transportation and Utility Networks

The Low Point single point moorage would be located between the inbound Vessel Traffic System traffic lane and the Clallam County shoreline. Once in operation, tanker's queuing near the SPM might cause a significant hazard to other inbound vessel traffic.

State Highway 112, a two-lane paved roadway provides access to the Low Point area from Port Angeles. Construction traffic would significantly lower service levels west of Port Angeles to the Low Point area, particularly during the summer when tourist traffic would coincide with construction traffic for both the onshore storage facility and the pipeline in this area.

The onshore storage facility and the additional pump station would be located within the Clallam County Public Utility Department service area. Service to these facilities would require approximately 25 megawatts additional power which might further aggravate possible regional power shortages.

### Recreation

No significant impacts to recreational activities are anticipated as a result of normal activities associated with the construction, operation, or abandonment phases of the SPM facilities, storage facilities or connecting pipeline system. Noise and activities associated with construction or abandonment of the SPM and onshore storage facilities could be offensive to campers using the nearby Lyre River State Park. The Elwha River is identified for statewide significance with scenic and recreational values.

Oil spills in the Strait of Juan de Fuca would impact an indeterminate number of recreationists using nearby beaches, tidelands, boat moorages, shellfish, and offshore fishing resources. For locations of these recreational activities, see Map Addendum.

Preliminary oil spill risk analysis indicates that a tanker oil spill incident off the SPM would affect marine recreation from Cape Flattery to Angeles Point. There could be losses to sport salmon fishing from Port Angeles to the Spit. Recreational shellfishing areas east of Pillar Point could be contaminated for 4 to 10 years. Oil fouling of public beaches, tidelands, boat moorages, and recreational boats at sea and in harbor would occur and affect recreationists for the short term.

### Social and Economic Conditions

The Low Point alternative and the pipeline would bring a peak population increase of 1,160 during construction and 202 during operation. This represents a 2.6 percent increase over the projected 1980 population for Clallam County. Most of the population would reside in Clallam County. The additional 28 miles of pipeline would require a greater number of construction personnel than the proposal, but the operation force would be less.

Assessed valuation of the alternative would be $94,400,000 and with the additional 17 miles of pipeline east of Green Point it would be $102,300,000. Property taxes would amount to $1,462,000 for the Low Point alternative, and $1,585,000 with the additional 17 miles of pipeline in the county.

Impacts of the community infrastructure would be similar to those created by the NTPC proposal. A detailed discussion is found in chapter 3. During construction housing would be insufficient to accommodate the population increase. Increased demands would be placed on police and fire personnel. The fire district which serves the Low Point area is rated 9 on Washington's 10-point insurance rating system, and would not be equipped to handle project related emergencies during construction and operation.

Changes in the quality of life in Port Angeles during operation would be less significant than with the proposed port at Port Angeles. Visual impacts would be significantly lower since residents would not see the facility from town. Perceived impacts to tourism due to visual degradation would be virtually nonexistent. Perceived impacts to air and water quality in the harbor would probably be lower than with the proposal. Recreational use of Ediz Hook would remain in its present state, and could possibly be increased by a city parks development program.

## ONSHORE FACILITIES ALTERNATIVE

### Description

Information on alternate onshore storage facilities was presented in the NTPC application to the Washington Energy Facility Site Evaluation Council (EFSEC). Site selection information has been adapted in the following description.

The NTPC selection of a site for the onshore storage facilities in the vicinity of the proposed location of the tanker unloading facilities in Port Angeles Harbor was based on the following criteria.

Availability of sufficient land (200 to 300 acres) in proximity to Port Angeles Harbor. Sites farther than 7 to 10 miles from the port are not normally feasible because of limitations and difficulties associated with unloading the tankers. Tanker unloading rates must be maintained at high levels to minimize the time tankers are at berth.

Acceptability of the site for construction of storage and related facilities. Topography, soil conditions, and drainage are factors that must be considered, as well as access. In this case, the site must be located such that routing of unloading pipelines from the tanker unloading facilities to the site is feasible, as well as routing of the main pipeline away from the site. Accessibility of the site to transportation facilities (road and railroad) is a factor that is important during construction and operation.

Proximity to transmission lines. This is an important factor, as the initial pump station for the pipeline system will be located at the onshore storage facilities and will require electric power.

Acceptability of the site with regard to local zoning ordinances and land use plans.

During the late spring and summer of 1976, NTPC investigated various sites in the vicinity of Port Angeles as shown on figure 9.4-8. A cursory examination was made of sites 1 and 2, located in the area west of the Fairchild International Airport. Site 1 is owned by the Port of Port Angeles and is used for dry log storage. Site 2 is an area located near the city sanitary landfill. These two sites were eliminated from further consideration because of the difficulties that would be encountered in routing unloading pipelines from the tanker berths along Ediz Hook, through the industrial area at the base of Ediz Hook, and through the urban area to the sites. Also, locating large storage tanks in the vicinity of the Fairchild International Airport could be considered a hazard to air traffic. Possible accidents could expose the storage site to damage from fire.

After sites 1 and 2 were eliminated, further investigations were undertaken to locate other potential sites that might meet the criteria. These investigations

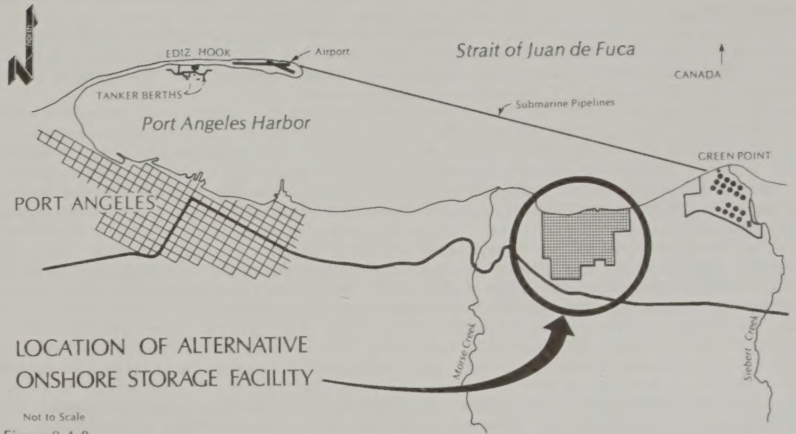

Figure 9.4-8

Ediz Hook

Bureau of Land Management

indicated that site 3, an area west of Green Point, was a suitable location for the onshore storage facilities. Title reports were obtained for all parcels of property making up site 3. Personal contacts were made with all property owners and negotiations were undertaken to obtain options for the property. After extensive negotiations, NTPC representatives were unable to obtain options for the property and efforts were initiated to find another suitable site.

The location in the vicinity of Green Point (site 4) was selected as a suitable site after efforts failed to obtain options for the property at site 3. Investigations determined that site 4 met all the criteria, although it was unclear if the onshore storage facilities were consistent with local zoning ordinances and land use plans that applied to sites 3 and 4. Title reports for the property at site 4 were obtained and negotiations were initiated with the property owners to obtain suitable options. Options for the property acquisition were obtained from July to September 1976. Therefore, site 4, Green Point, was designated the proposed site for the onshore storage facilities and site 3 the primary alternative.

Site 3, the primary alternative site for the onshore storage facilities, is located approximately 4.6 miles from the tanker unloading facilities on Ediz Hook. This site meets all the criteria for an onshore storage facilities site. The topography, soil conditions, and drainage of this approximately 545 acre site are suitable for construction of onshore tanks and other related facilities. The Chicago, Milwaukee, St. Paul, and Pacific Railroad crosses the site, providing rail access. Road access can be readily provided from a presently unimproved road that connects the southern portion of the site with U.S. Highway 101. Electric service could be provided by a transmission line located approximately 1 mile south of this alternative site.

This site (Site 3) is primarily forested, with a small agricultural/pasture area of approximately 92 acres in the northern central portion. The onshore storage facilities would be compatible with existing land uses if the facilities are sited away from a nearby residential area and if steps are taken to preserve wooded areas as a screen and buffer.

The Clallam County Comprehensive Plan indicates that the site is at the western boundary of an area designated for future "agricultural and residential" use. The area immediately to the west is designated for future "residential" use. All other bordering lands are classified "agricultural and residential". On the county's temporary interim zoning map, this site is classified as an R-2, Suburban Residential Zone. The exact meaning of this zoning is unclear.

The Clallam County Shoreline Master Program (Clallam County Shoreline Advisory Committee 1976) designates the shoreline along the Strait of Juan de Fuca as a conservancy environment in the area where the Strait constitutes the northern boundary of the alternative site. While the Economic Development Element of the program does not permit commercial and industrial developments in conservancy environments, the section that regulates "use activities" indicates that utility lines in shoreline areas are permitted if "underground so as to do minimal damage to the aesthetic qualities of the area." Furthermore "upon completion of the underground installation the shoreline must be restored to its original configuration and replanted." Construction of the submarine pipelines might not comply with regulations governing development in conservancy environments, since it is not possible to restore the shoreline bluff at Green Point to its original configuration.

Based on the above evaluations, it was concluded that it would be feasible to construct onshore storage facilities at site 3. However, as previously mentioned, options could not be obtained on the property (NTPC 1978).

The environmental impacts of site 3, the primary NTPC alternative located west of the Green Point site, would be similar to construction impacts of the proposed site at Green Point. Construction and operation impacts on the air quality, aquatic, terrestrial, and social and economic environment would be similar to the proposal due to the proximity of the alternative site to Green Point. However, the alternative could be in conflict with Clallam County land use plans and zoning. Construction of the submarine pipelines could be in conflict with the Clallam County Shoreline Master Program.

## ROUTE SEGMENT ALTERNATIVES

The route segment alternatives described in this section represent a selection of variations of The Northern Tier Pipeline Company's proposed pipeline route. These have resulted from consideration of legal requirements, avoidance of major environmental problems, avoidance of Indian Reservations, avoidance of special Federal lands, and public preferences. Each route segment in the following discussion explains its origin, the description, and an impact analysis by environmental component.

## AROUND PUGET SOUND

### Description

The around Puget Sound pipeline segment would originate at the onshore storage facilities on Green Point in Clallam County, Washington and would intersect the proposed pipeline route at North Bend, Washington, a distance of 198 miles (figure 9.4-2).

After leaving the onshore storage facility, the route would proceed due south, crossing U.S. Highway 101 approximately 6 miles east of Port Angeles and 1 mile south of the tank farm, continue on 2.5 miles, south where it would intersect the Bonneville Power Administration (BPA) transmission line right-of-way. The pipeline would parallel the existing BPA right-of-way across Clallam County and enter Jefferson County southeast of Blyn. The route would cross the Dungeness River Southwest of the town of Sequim. South of Port Discovery Bay, the route would turn southerly and parallel the Hood Canal and U.S. Highway 101, and the BPA right-of-way across Jefferson and Mason Counties for approximately 70 miles. It would cross several major rivers, including the Quilcene, Dosewallips, Duckabush, Hamma Hamma, and the Skokomish, along with several minor rivers and creeks. Just north of the town of Shelton, the route would skirt the edge of the Skokomish Indian Reservation.

South of Shelton, the route would join and parallel the Northwest Pipeline corridor for approximately 20 miles in a southeasterly direction to a point 1 mile east of Interstate 5. The route would leave the Northwest Pipeline corridor and proceed easterly toward the town of Rainier then northeasterly toward the town of Enumclaw. This section would be on approximately 60 percent private right-of-way and 40 percent existing railroad and high-voltage transmission line right-of-way.

The major rivers to be crossed are the Deschutes and Nisqually in Thurston County, the Puyallup and Carbon in Pierce County, and the White River in Pierce and King Counties. North of Enumclaw, the route would parallel the BPA right-of-way in a northerly direction, crossing the Green River west of Kanaskat.

From the BPA substation near Kanaskat, the route would head northwesterly and then northerly, skirting the City of Seattle Cedar River Watershed near Hobart. It would parallel State Highway 18 and the BPA right-of-way to a point near Rattlesnake Mountain.

West of the town of Snoqualmie the route would proceed southeasterly toward North Bend generally paralleling the BPA right-of-way and Interstate 90. Just east of North Bend the around Puget Sound segment would intersect the proposed pipeline route, pipeline mile 128, for a total distance of 198 miles, compared to 128 miles for the proposed route.

## Air Quality

Air pollutant concentrations along the proposed corridor are generally low since the line would traverse mostly rural areas. Sulfur dioxide concentrations exceed the standards in Tacoma, Washington.

High ozone readings occur in the Seattle area primarily in summer. Hourly average concentrations as high as 0.16 parts per million (ppm) were observed in 1978. In that year there were 14 days with violations at one Seattle location. The Non-attainment Area for ozone covers all of the Seattle-Tacoma metropolitan area and extends from Puget Sound eastward to the foothills of the Cascades near North Bend.

Construction of the pump stations and pipeline would result in temporary emissions from combustion engines of construction equipment. The emission level would be small enough that pollution levels outside the immediate construction site would be negligible.

Fugitive dust would be generated during construction activities. However, impacts would be confined to the immediate vicinity of the site and would be of limited duration.

During the operation phase, impacts on air quality are expected to be negligible.

The only pollutants that would be emitted from a typical pump station during the operation phase would be hydrocarbons from the surge tank, if one is installed. Hydrocarbon concentrations near the proposed facilities would not exceed the federal 3-hour average standard of 160 $ug/m^3$, and ordinarily would be negligible.

Emissions from the proposed pipeline would be negligible during the operation of the pipeline and no significant air quality impacts would be expected.

## Noise

Noise levels along the pipeline corridor between Port Angeles and North Bend are generally low. Noise levels would be typical of small towns, with most noise sources originating from local traffic and highways, and light commerical activities.

The State of Washington has established noise regulations. Noise from temporary construction activities between the hours of 7 a.m. and 10 p.m. is specifically exempted.

A limited number of residences would be subject to noise from construction activities at the proposed pump stations. Construction would take place over a period of about 12 months.

Residences located about 1,500 feet from the construction site would experience equivalent noise levels of about 70 dBA. This would cause a significant increase above background levels for rural locations, and might cause some annoyance. Residences located about 4,000 feet from the construction site would experience noise levels of about 55 dBA. Most of the pump stations would be located away from residential areas.

The impact of pipeline construction would be temporary. The intensity and duration of impact would depend on the distance of the receptor from the route alignment. Significant impact may occur up to 4,000 feet from the construction activity but would usually last less than a week.

### Operation Phase

During the operation phase the primary source of noise would be the pump stations. A typical station would be equipped with electrically driven pumps that would produce a noise level of 69 dBA at a distance of about 100 feet. At a distance of 1,500 feet the equivalent level would drop to 50 dBA. At distances beyond 4,000 feet this would be below background levels.

## Topography

This route segment alternative, from the onshore storage facilities (pipeline mile 0) to the intersection with the proposed pipeline (about pipeline mile 196), would cross topography similar to, but slightly steeper than, the proposed route. It would consist of a terrace-like glacial outwash plain dissected by numerous fast flowing streams in relatively steep sided gullies between pipeline mile 0 and 78 (Olympic Mountains), rolling morainal hills with relatively flat areas with broad, steep-sided valleys and aggrading streams between pipeline mile 78 and 180 (Puget Trough), and low (2,000-3,000 feet), moderately steep (15 to 25 percent) mountain peaks and glacial outwash plains between pipeline mile 180 and the intersection with the proposed route (foothills of the Cascade Range).

Topographic impacts along this route segment alternative would be much the same as those that would be encountered along the proposed route. Impacts would be relatively minor, would be visual in nature and would consist primarily of landscape changes. Although this route segment alternative would cross slightly steeper terrain, the amount of land disturbed (about 12 to 18 acres per mile) would be nearly identical to the proposed route.

## Geology

This route segment alternative would encounter geologic material similar to that encountered by the proposed route. It would consist primarily of variable thicknesses (less than 100 to over 300 feet) of Quaternary glacial debris and Quaternary alluvium, underlain by Tertiary volcanic rock (basalt) and nonmarine sediments in the Olympic Mountains (pipeline mile 0 to 78), and Tertiary volcanic (basalt, andesite) and crystalline (granite) rocks and small areas of Mesozoic and Tertiary nonmarine sediments in the foothills of the Cascade Range (pipeline mile 180 to 196), and overlain by two volcanically induced mudflows in the Puget Trough (pipeline mile 145 and 160-168).

Like the proposed route, impacts to the geologic materials along this route segment alternative would be minor and would consist of the removal of large amounts of geologic material and some alteration of the physical characteristics (permeability, porosity, moisture content, etc.) by construction. Although the average slopes along the route segment alternative is slightly greater, the amount of material excavated per mile would be comparable for both routes. Consequently, the geologic impacts would be essentially the same.

### Geologic Hazards

Geologic hazards that could be encountered by this route segment alternative would be the same as those encountered by the proposed pipeline and would consist of seismicity (ground shaking, surface fault rupture, liquefaction), slope instability, and outburst flooding.

### Seismicity

Like the proposed route, this route segment alternative would be within a seismically active area that has been classified by the 1976 Uniform Building Code as a Seismic Risk Zone 3 (maximum earthquake damage expected). However, it has experienced a greater frequency of strong earthquakes (4.8 or greater on the Richter scale), including two that registered 6 or higher.

While several surface fault ruptures have been identified in the immediate vicinity of both routes, only along the route segment alternative are found faults (5) that have shown apparent movement during Quaternary time. Two of these, located near Lake Cushman have shown apparent movement during the Holocene (past 10,000 years) and are considered active. The remaining three faults, Blyn, Bottom peninsula, and Dow Mountain have shown apparent movement during the Pleistocene (2 to 3 million years) and are considered "potentially" active. None of these faults would be directly crossed by the pipeline.

In addition to the five Quaternary faults, several geophysical (magnetic or gravity) anomalies are found in the vicinity of this route segment alternative. Three of these anomalies lie within the pipeline corridor. One is parallel to the pipeline along Hood Canal, and two are crossed by the pipeline at approximately mile 6 and mile 119. These features have been tentatively identified as possible faults and represent potential geologic hazards. However, they may also represent geologic structures that are nontectonic in nature.

Potential liquefaction problems that would be encountered by the around Puget Sound route segment would be in material similar to the proposed route and would be found along the eastern flanks of the Olympic Mountains, Skokomish Valley (pipeline mile 74 to 80), Oyster Bay (pipeline mile 89 to 92), and Lacamus Creek to Muck Creek (pipeline mile 134 to 138).

While both routes are located in an area of high seismic activity, this route segment alternative has experienced more strong earthquakes than has the proposed route. It would also pass within 2 miles of two active faults (near Lake Cushman), and three potentially active faults (Blyn, Bottom Peninsula, and Dow Mountain) and encounter more zones of potential liquefaction. Consequently, the potential impacts from seismic activity (ground shaking, surface fault movement, and liquefaction) would be significantly greater along the route segment alternative than along the proposed route.

### Slope Instability

Although areas of slope instability are found along both routes, the higher level of seismic activity and more recent fault movement along the route segment alternative has created more unstable and potentially unstable slopes than along the proposed route. This is particularly true along the eastern flanks of the Olympic Mountains and the western foothills of the Cascade Range, where large landslides have occurred near Mount Walker (pipeline mile 36 to 39), Mount Turner/Green Hill (pipeline mile 40.6 to 42.5), Dow Mountain (pipeline mile 66 to 68), and Tiger Mountain (pipeline mile 180 to 185). Consequently, the anticipated impacts from slope instability would be substantially greater along the route segment alternative.

### Outburst Flooding

While outburst floods could occur along both routes, only those locations with the greatest potential for outburst flooding are identified. All of these are found along the route segment alternative and consist of the Dosewallips River (pipeline mile 44), Nisqually river (pipeline mile 128), Puyallup River (pipeline mile 148), White River (pipeline mile 159), Green River (pipeline mile 171) and Cedar River (pipeline mile 175). Consequently, potential impacts (stream scour and stream bank erosion) would be much higher and pose a greater threat to pipeline integrity along the route segment alternative than along the proposed route.

### Mineral Resources

As neither route would cross active mineral recovery operations or known areas of high mineral development potential, anticipated impacts would be identical.

## Soils

A review of published soil surveys indicates that approximately 75 percent of the soils are underlain by glacial deposits, 13 percent are mountainous, 7 percent are underlain by bedrock, 3 percent are alluvial, and 2 percent are organic. About 10 percent are poorly drained. Total amount of fair to good productive soils is about 600 acres, two-thirds of which could be classified as prime farmland. This compares with 320 acres of prime farmland that would be traversed by the proposed route. Stongly sloping and very steep slopes total about 560 acres, whereas only 150 acres of similar lands would be encountered along the proposed route. High seasonal water tables occur on 1,290 acres as compared with 530 acres on the proposed route.

Pacific Border

This physiographic region consists of the Olympic Mountains and Puget Trough subregions. The former extends from the begininng of the route to approximately pipeline mile 78. Soils are moderately deep to shallow loams, gravelly loams, and silty clay loams with fine-grained alluvial deposits throughout. Dominant soil series are Clallam, Hoodsport, Shelton, Grove, and unidentified soils of rough, mountainous lands. Steep slopes with gradients ranging to 50 percent occur. Water erosion potential would be high on those slopes. Shrink-swell potential is low. Corrosivity to steel is medium to high. High water tables (to within 12 inches of the surface) are common on nearly level to gently sloping lands. Many soils have high compressibility and low structural bearing capacity. Topsoil suitability for revegetation is generally poor.

The Puget Trough subregion extends approximately from pipeline mile 78 to 180. Soils are highly permeable, gravelly, and stony loams formed in alluvium. Principal soil series are Everett, Tumwater, Spanaway, Alderwood, and Buckley. Perched groundwater tables occur 2 to 3 feet below ground surface. Slopes are nearly level to moderately sloping and occasionally steep. Surface textures are mostly gravelly silt loams and sandy loams. Depths to cobble and gravel are 2 to 5 feet. Permeabilities range from slow to moderately rapid. Shrink-well potential is low. Steel corrosion potential is high to medium. Potential for wind erosion is low; water erosion potential is low to medium.

The abundance of surface gravel make these topsoils undesirable for revegetation but desirable for erosion control. Chief limitations of the Puget Lowlands soils are cemented hardpans, gravelly and cobbly subsoils, poor drainage, and occasional small areas of peat and muck.

Cascade Range

The few miles between pipeline mile 180 and the intersection with the proposed route east of North Bend the around Puget Sound segment is in the westernmost section of the Cascade Range. Soils may be shallow gravelly, stony, and medium textured on gentle to steep slopes.

Construction operations might remove vegetative ground cover from the length and width of the pipeline right-of-way and the pump station sites and from access roads that would be required in excess of the present available roads. Soils on an area of 2,300 acres would be disturbed, compared to 1,300 acres on the proposed route.

Annual soil loss ranging from 2 to 50 tons per acre could occur from water erosion. Actual amounts would depend upon topography, precipitation, and the degree of soil cover removal during construction. These rates would be reduced to less than 5 tons per acre per year after complete revegetation.

Soils of marshes, peat bogs, and other seasonally wet areas could be severely impacted by pipeline construction. An estimated 45-50 acres could be reduced in productive capacity by as much as 25 percent for several years.

Other impacts such as soil loss by dust emission and loss of productive capacity because of soil profile mixing, compaction, and oil spills would be similar to those discussed for the proposed route.

Aquatic Recources

Water Quality

The pipeline route segment would cross the Puget Sound Basin from the onshore storage facility (pipeline mile 0) to North Bend, Washington. Seventeen (17) major streams would be crossed in the basin.

Selected river characteristics for Puget Sound Basin rivers are summarized in table 9.4-11. Width, depth, velocity, gradient, scour depth, and streambed composition are based on field inspections of the proposed river crossings in spring of 1978. Low flow and 100-year flow flood plain widths are based on U.S. Geological Survey (USGS) gaging stations at or near the proposed crossings and/or by county flood-hazard maps.

Variation of discharge for gaging stations near the major river crossings are presented in table 9.4-12. Instantaneous minimum and maximum discharges recorded in cubic feet per second (cfs) for the period of record and for the 1976 water year (October 1, 1975 through September 30, 1976) are listed if data are available. The most current year of record is used for stations that were discontinued before the 1976 water year. Mean monthly discharges for April through November are based on 1976 or most current year of record. All discharge measurements are taken from U.S. Geological Survey published records, except as noted. Seven-day low flows with a 10-year recurrence interval are included when data are available (Pacific Northwest River Basins Commission (PNRBC) Ap. III, Tab. 30).

Water Quality data for major river crossings are summarized in table 9.4-13.

Puget Sound Basin-Groundwater

The Puget Sound Basin, pipeline mile 0 to 205, can be subdivided into two groundwater regions, the Puget Sound Lowlands and the Puget Sound Lowland-Cascade Range transition zone.

The most significant aquifers in the Puget Sound Lowlands, pipeline mile 0 - 120, are the alluvial and glaciofluvial deposits covering the valley floors and lowlands (PNRBC 1970). Water levels in the unconfined aquifers lie between 25 and 50 feet below the surface, with perched zones that have water levels of 10 feet or less (Molenaar and Noble 1970). Recharge is primarily from precipitation and secondarily from runoff. Discharge is through springs, both onshore and offshore. Water is used for domestic, agriculutral, and livestock purposes.

Groundwater in the Puget Sound Lowland-Cascade Range transition zone, pipeline mile 120 to 125, is generally encountered within 0 to 50 feet of the land surface. Areas of shallow water that may be less than 10 feet below the surface exist in the vicinity of pipeline mile 134 and 140 and in river and stream valleys between pipeline mile 144 and 198 (Luzier 1969).

Recharge to the unconfined aquifer is from rainfall and snowmelt in the transition zone. Discharge, particularly in the more mountainous region of the transition zone, is through springs which are the principal supply to streams during late summer (PNRBC 1970). Use of ground water from the unconfined zone is for domestic, irrigation, and livestock supply.

TABLE 9.4-11 CHARACTERISTICS OF MAJOR RIVER CROSSINGS--PUGET SOUND BASIN

| River Crossing | | | | | | | | 100 Year Flow | | Low Flow | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Name | Pipeline Mile | Survey Date | Width (feet) | Depth (feet) | Velocity (ft/sec) | Gradient (ft/100ft) | Scour Depth (feet) | Max.Width (feet) | Expected Occurrence | Max.Width (feet) | Expected Occurrence | Stream Bed Composition |
| Dungeness | 10 | 4/78 | 50 | 2 | 3-5 | 2.5 - 3 | 10 | 270-350 | Dec-Feb | 20± | June-Aug | Coarse gravel, cobbles, boulders |

Source: U.S. Geological Survey & EPA Storet Data

The groundwater is generally good quality, with constitutents well within U.S. Environmental Protection Agency drinking water limits. This water is of the calcium-magnesium bicarbonate type (Walters and Kimmel 1968). Most of the groundwater contains less than 200 parts per million (ppm) of dissolved solids although higher concentrations may occur near shore lines as a result of seawater encroachment (PNRBC 1970 App. III). The hardness of the water varies from soft, less than 60 milligrams per liter (mg/l) to hard, over 200 mg/l. Iron concentrations may be high in localized areas within the basin. High sulfate concentrations are present in some of the Cascade Range aquifers.

Pipeline construction would affect surface water quality by increasing suspended sediment and turbidity during clearing, trenching, pipe installation, and backfilling operations. Sediment in runoff water from the cleared right-of-way would reach surface water. The amount of sediment contributed would depend on intensity, duration and frequency of rainfall, soil type, and the length and angle of the slope adjacent to the streambank. At major river crossings potential sediment from trenching activities would range from 2 to 6.5 cubic yards per foot of stream channel width, depending on trench depth and trench wall collapse. Suspended sediments would be carried varying distances downstream before they settled out, depending on stream velocity, slope and size of sediment particles. Generally the smaller the particule the farther downstream it would be carried. Trench size, stream velocity crossing width, streambed composition, and estimated increase in suspended sediment concentration from major streams crossed by the proposed route are included in table 9.4-14.

Most streams would eventually flush themselves and return to preconstruction quality. Short-term increases in turbidity, total suspended solids, and color would decrease light penetration, and subsequently lessen photosynthetic activity. Potential organic load increases caused by streambed disturbance, such as resuspended decomposing organic material, could exert a higher oxygen demand and thus reduce the dissolved oxygen content of the water. Reoxygenation caused by turbulent river flow and the diffusion of atmospheric oxygen would eventually replenish the depleted dissolved oxygen. Dilution by inflow of cleaner water would decrease turbidity, color, and nutrient levels. Generally, impacts on water quality from construction would be short term, lasting less than 1 month.

Ground water flow characteristics would not be significantly affected by the construction of the pipeline, although some pipeline sections would lie below the water table. During construction, dewatering of the trench in seasonally high water table regions would be required. The displaced ground water could be pumped into adjacent drainages where it would recharge aquifers, or be mixed with other surface water without change in quality.

The pipe would be hydrostatically tested for leaks. Test water would be withdrawn from streams and rivers along the route at a proposed rate of 6 cubic feet per second. If tests were conducted during periods other than low flow no significant impacts would occur. For test water with dissolved oxygen content greater than 13 milligrams per liter, soda ash could be added as a pipe corrosion preventative. The pH of the test water would be raised to 9. To avoid anerobic bacterial corrosion, a bacteriacide would be added to test waters remaining in the pipe for longer than 2 months. Raised pH and bacteriacide impacts could occur in test water discharge areas. Intensity of impact would depend on dilution effect of the stream flow,

Juvenile salmon released from the Dungeness Hatchery upstream migrate through this reach of the Dungeness River in Western Washington on their way to the ocean.

background pH, and the volume of hydrostatic test water discharged. Temperature of discharged test water would probably range from 50°F to 60°F. If temperatures for streams receiving test water were considerably higher or lower than the 50°F to 60°F range, a short-term, localized impact would result.

The discharge procedure for the test water could be a source of impact. If discharged into a stream under pressure, it could cause gouging erosion, undercutting, or dispersion of bank and bottom sediments. Discharge into a treating pond and then to an existing waterway could create other impacts. Percolation of hydrotest water from the holding pond could contaminate subsurface aquifers, or a leak in the impoundment would allow untreated water to flow over the landscape. If discharge of treated test water were released via siphon or low pressure pumping no significant impact would result.

No impact on groundwater is expected from hydrostatic testing unless a rupture of the pipeline occurs. Areas of seasonally high or perched water tables could be contaminated with treated test water. If no soda ash or bacteriacide were added to the test water, no water quality degradation would occur.

Under the operation phase, only minor impacts from maintenance are anticipated. Seasonal flooding would be expected in uncontrolled rivers. Major runoff events could expose the buried pipe and necessitate maintenance operations. Short-term sediment impacts would occur at the crossings and downstream. Impacts would be similar, although of less intensity, and duration, than those at construction operations.

The most significant impact of pipeline operation would result from a pipeline rupture spilling oil into surface or ground water. For new piplines, there is a leak rate of 0.0022 leaks per mile per year (OIW 1978).

In the chance of a spill, the severity of impact on stream water would depend on the amount of oil spilled, chemical constituents of the oil, time before oil containment, topography of the area, volume of stream flow, and time of year. Table 9.4-15 represents maximum potential oil spills based on block and check valve locations, length of crossing, shutdown and leak detection time (12 minutes), and volume of thoughput at all major river crossings requiring a U. S. Army Corps of Engineers permit.

## Biological Components

Major cold water species include five species of salmon and five species of trout. All of the salmon and three species of trout hatch in freshwater, migrate as juveniles to saltwater where they live until maturity, and return to freshwater as adults to spawn (anadromous or searun). The salmon die after spawning. The other two species of trout spend their life cycle entirely in freshwater.

Salmon contribute to the marine commercial, sport, and Indian fisheries and to the freshwater sport and Indian fisheries. Resident trout are limited to freshwater sport angling. Anadromous trout (mostly steelhead) contribute to both the ocean and freshwater sport and Indian fisheries. Some western Washington streams have been identified as significant habitat for these species.

South Fork Snoqualmie River

There are no known threatened or endangered fish species along this pipeline route segment according to the list published by the U.S. Fish and Wildlife Service. This list was published in accordance with Public Law 93-205, The Endangered Species Act of 1973.

The following tables are included to identify the fisheries resources along the pipeline corridor: table 9.4-16 identifies major drainages, the streams crossed, the pipeline mile, and the fish species of concern in each stream. An overall evaluation of the fishery within each stream is also provided. Table 9.4-17 presents information about the anadromous fisheries resources in selected western Washington streams.

Minor impacts on fishery resources would result from vegetation removal and test water discharge during the project construction phase. Removal of streamside vegetation would decrease escape and resting cover for fish, decrease the quantity of terrestrial insects dropping into the stream as food items for fish, and increase water temperatures through shade reduction. The extent of these impacts would depnd on the density and type of vegetation, the percentage of stream covered by vegetation, and on the stream characteristics and fish habitat at specific sites. These impacts would last for the life of the project since only low shrubs would be allowed to become reestablished; they would be minor since only short stream segments would be affected.

Instream trenching activities would destroy undercut banks which serve as fish resting and hiding areas. As habitat is destroyed, fish would not be killed, but rather displaced to other areas within the stream, thus increasing competition with other fish. Both adult and juvenile fish would be impacted. This impact would last for the life of the project and would reduce the number of fish inhabiting the disturbed area. Fish numbers in undisturbed areas, where competition has increased would tend to remain constant, reducing fish populations.

Hydrostatic test water would be withdrawn and discharged at the end of the construction phase. Fish entering the pipe during water withdrawal and entrained in the system would suffer 100 percent mortality because of pressures generated in the pipe. It is not expected that the number of fish impacted in this manner would be significant. There would be no significant impact resulting from test water discharge.

Fuel oil could be spilled by equipment operated near streams. Spills would probably be of short duration and volumes would probably be limited to a few gallons or less. Because of dilution and low volumes, minor impacts would be expected. The impact would be similar to that for a pipe rupture described in the operation phase.

More serious impacts would result from sedimentation of streambeds in spawning areas and in areas where large concentrations of aquatic insects are produced. Sediments would originate from two sources: the streambank and streambed. The removal of streamside vegetation during the construction phase would expose large areas of soil on the streambanks. These would be subject to erosion until revegetaion occurred Factors which would influence erosion include percent and length of slope, soil type and disturbance, amount of precipitation, and runoff patterns. Sediment would begin to enter the streams early in the construction phase (depending on runoff) as vegetation was removed and soil was disturbed. Instream trenching activities would cause downstream sedimentation as disturbances to the streambed occurred. Sediment arising from instream trench excavation would be most noticeable during the actual construction activity which would last several days in most cases. Factors influencing the

1/ Pipeline mile where stream crossing would occur.

2/ Overall value of fishery including all species. Value based on the following considerations: fish population size, habitat quality, angler preference, access, availability, commercial importance, state and federal stocking, local and regional importance, etc.

H = High Value M = Moderate Value + = Species present but not evaluated.

distribution and quantity of sediment downstream from the crossing would include bottom composition, water velocities, streambed slope, and excavation methods.

Most of the sediment would be deposited within a few hundred feet of the crossing area with the smaller particles traveling farther downstream. Impacts should last 1 year or less since most of the sediment would probably be flushed out during the first period of high flows. This flushing action would be greater in streams with high flood flow velocities and high gradients. Sediment would continue to impact fish and insect populations as it moved downstream but the impacts would probably decrease because of sediment dispersal.

Specific concentrations of aquatic insect production have not been identified, but their occurrence is likely immediately downstream from some crossings. These populations would be impacted by the sediments from streambank erosion and by those generated during instream trenching. Sediment related impacts on insect populations are well documented. Sediment would reduce insect populations by: scouring the streambottom and dislodging insects, covering the streambottom and smothering the larvae and eggs, clogging the gills and suffocating the larvae, and preventing larvae from attaching themselves to rocks. The most important insects impacted would be mayflies, caddisflies and stoneflies. Under the worst-case situation the entire production of these insects might be completely eliminated for several hundred feet downstream from the crossing for 1 year and reduced considerably for several years after construction if bank erosion and or stream scouring occurred. These insects serve as the most important food source for juvenile salmon and juvenile and adult trout. A reduction in the supply of these insects might retard fish growth and reduce survival. The juvenile salmon in western Washington streams that feed mainly on these insects before migrating to the sea, would be most affected. However, the impact would probably not be noticed since only small, local populations of fish would be affected and the reduced growth and survival rates would probably be within the normal range.

Sediment desposition in spawning areas would have the most serious impacts. Sediment would settle in spawning gravels and fill in spaces, blocking water circulation to eggs deposited in the gravel. Sediment would also filter through the gravel and cover incubating eggs. Decreases in water circulation incubating eggs can cause mortality by suffocation through a reduced oxygen supply, and by preventing toxic respiratory by-products of the developing eggs from being washed away. Sediment deposition can also prevent newly hatched fry from emerging from the gravel and lead to poor quality and reduced survival of fry that do emerge. Deposition of sediment before spawning would have impacts similar to those previously described, since sediment is redistributed during the spawning process. If sedimentation were severe, 100 percent mortality could occur within the impacted area, which would generally extend several hundred feet downstream from the crossing. Most of the sediment would probably be flushed out of the gravel during the first period of high flows, with the remainder of the sediment moving downstream in subsequent years. Sediment would tend to settle in areas of low water velocities such as pools, lakes, and estuarine areas.

Sediment which remained in the gravel for one year or less would only impact one year-class of fish. Since the different species of salmon and trout spawn at different times of the year and eggs can be found in the gravel during nearly all months of the year in most streams, it would be possible to impact all species within a stream. If concentrated spawning areas were severely impacted by sediment, 100 percent mortality of all fish production within the impacted area (several hundred feet downstream) could occur. Since spawning for particular species normally extends for a considerable distance both upstream and downstream from the crossing area (several miles in some streams), the loss of fish in a relatively short stream segment should not have a critical effect on the population. In streams in which spawning habitat is limited to a few thousand yards or less, the loss of one year-class of fish within the impacted area would be significant and the overall stream population level for a particular species might fall below the normal range. Several spawning cycles might be required for these impacted populations to recover to previous levels. Streams in which this might occur include the Duckabush, Hamma Hamma Rivers and other short streams along Hood Canal. Only under certain circumstances such as a low number of spawning adults, severe sedimentation, and loss of production in other areas of the stream, would the population be reduced substantially. Several cycles of the impacted year-class might be required for the population to return to earlier levels. Since some searun fish return to spawn every year and others every 2, 3, or 4 years, up to 20 years may be required for some poulations to fully recover. It is likely that reductions would be noticed in ocean commercial, sport, and Indian fisheries. However, substantial reductions could all affect river sport, Indian fisheries and other terminal fisheries in estuaries.

Sediment would also fill in pools. Fish using these pools as resting areas would be displaced. Increased competition with displaced fish should not have a significant impact on fish populations. Suspended sediment can clog and irritate the gills of fish and interfere with respiration. Severe conditions might extend downstream for several hundred yards. However, the number of fish expected to suffer mortality would be quite small, since fish would usually avoid such conditions, if at all possible.

The most important impact during the operation phase would result from a leak or pipe rupture. Such an event could occur at any stream crossing. The leak detection system would be capable of sensing a 0.5 percent loss of throughput volume but would allow a leak under this limit to go undetected. A leak of up to 3,540 barrels per day at a throughput of 709,000 barrels per day and up to 4,660 barrels per day with a 933,000 barrels per day throughput could occur and would continue until detected visually and stopped. If oil were to spill, aquatic insect egg, larvae, and adult stages, juvenile, and adult stages could be impacted. An oil spill could impact fishery resources in the following ways: 1) oil may act on the body and gill surfaces of fish and interfere with respiration; 2) oil may coat and destroy algae and other plankton; 3) settling oil substances may coat stream bottoms, destroying bottom organisms and interfering with spawning areas; 4) oil may be ingested by fish and taint the flavor of the flesh; 5) organic materials may deoxygenate waters sufficiently to kill fish; 6) heavy coatings of oil on the surface may interfere with natural reaeration and photosynthesis; and 7) insufficient concentrations, some water soluble fractions may exert a toxic action on fish or fish-food organisms. A fuel oil spill associated with equipment operation would have similar though smaller impacts.

Oil would probably spread downstream for several miles depending on streamflow characteristics and detection and shut-down times. The severity of impacts could range from the complete elimination of all fish and insects for several miles downstream if spill volumes and oil concentrations were high to no detectable impact, if spill volumes and oil concentrations were low. If elimination of a large percentage of fish occurred, several years would be required for the populations to be reestablished. It is probably that prespill population levels would eventually be achieved. Direct impacts would only last for the duration of the spill or until clean water replaced oil-contaminated water.

Large spills could also have major impacts on the salmon fishery resource in western Washington streams, particularly if large concentrations of juvenile salmon were eliminated. Since salmon spawn every 2, 3, or 4 years, depending on the species, the spawning run could be reduced for several years. Pink salmon, which spawn predominately every other year could be noticeably reduced for many years. Very few Washington streams support sockeye salmon and since the Cedar River contains the largest run a reduction of this population could be critical.

Concentrations of juvenile salmon released from hatcheries could also be seriously reduced if they were exposed to an oil spill as they migrate to the sea or as they spend time growing in streams before their migration. Fish released both upstream and downstream from hatcheries could be impacted. Two hatcheries present another problem. The Puyallup and Issaquah salmon hatcheries draw water downstream from the proposed crossing area for use in the hatchery facilities. If oil-contaminated water were allowed to enter these hatcheries, even in low concentrations, the entire production exposed to the oil could be eliminated. This would be a critical impact.

Population reductions to salmon resulting from an oil spill would probably not be noticed in the ocean sport, commercial, or Indian fisheries. However, if impacts were severe, reductions could be noticed in the river sport and Indian fisheries.

Impacts resulting from sedimentaion would also occur during the operation phase, but would decrease as the amount of sediment reaching streams decreased as stream bank vegetation occurred. However, specific unidentified sites could continue to be a source of sediment for many years if revegetaion were not successful. The impacts would be similar to those discussed in the construction phase, but of lesser magnitude. Sites most likely to be a problem are those with steep slopes, unstable soils, and high runoff potential such as the Dosewallips, Duckabush, Green, and Raging Rivers. Some crossings could continue to be problem areas throughout the project life as streambed scouring exposed the pipe. Streams likely to be a problem in this regard are meandering streams and streams with unstable bottoms and high flow velocities such as the Dungeness, Duckabush,and Nisqually Rivers. Scouring would disturb sediment and carry it downstream. Sediments could also be resuspended and redistributed if it became necessary to operate equipment in streams to rebury the exposed pipe. Impacts would be similar to those described in the construction phase, but would be of lesser magnitude, since the disturbance would not be as great.

Fisheries impacts would be greater for the alternative due to the greater number of stream crossings. Impacts for stream crossings are shown in tables 9.4-18 and 9.4-19.

## Marine Resources

### Physical Components

The inland waters discussed in conjunction with the pipeline system are the Puget Sound Basin south of Admiralty Inlet and Hood Canal. The main basin of Puget Sound

## TABLE 9.4-18 SUMMARY OF IMPACTS ON FISHERY RESOURCES IN WESTERN WASHINGTON STREAMS[1]

|  | Construction |  |  |  | Operation |  |  | Abandonment |
|---|---|---|---|---|---|---|---|---|
|  | Sediment Impacts |  |  |  | Oil Spill Impacts |  |  | Sediment Impacts |
| Stream | Pipeline Mile | Significant Spawning Habitat[2] | Streambed Sediment[3] | Streambank Erosion[3] | Hatchery Operations[4] | Indian Fisheries[5] | Juvenile Fish Populations[6] | Streambank Erosion[7] |
| Dungeness River | 10 | Yes | Low | Moderate | Moderate. Loss of exposed juveniles released upstream and downstream. | Disrupted and reduced catches | High | Low |
| Little Quilcene River | 34 | Yes | High | Low | -- | Disrupted and reduced catches | High | Low |
| Big Quilcene River | 35 | Yes | Moderate | Low | Moderate. Loss of exposed juveniles released upstream | Disrupted and reduced catches | High | Low |

[1] Refer to table 2.1-65 for more detailed information concerning spawning habitat, hatcheries, and Indian fisheries.
[2] Presence of significant spawning habitat for salmon and trout in crossing area.
[3] Estimated impact on salmon and trout populations produced in area immediately downstream from crossing. Based partly on information submitted by Fugro (1978) and Roger Low Assoc., Inc. (1978). Assumes actual spawning habitat is present and utilized substantially. High = Reduction would be below normal range of fluxuations. Moderate = Reduction would be near the low range of fluxuations. Low = Reduction would be within normal range of fluxuations
[4] Estimated impact on fish populations associated with appropriate hatchery. Assumes large number of fish exposed to oil. Delay of migrating spawners could occur in all streams and could lead to decreased production.
[5] Estimated impact on Indian River fisheries. Disruption of fishing activities would occur during and immediately after an oil spill. Reduced catches would occur on subsequent spawning runs and during the current run if adult mortalities occur.
[6] Estimated loss of naturally produced salmon and trout (non-hatchery fish). Based on length of stream, number of fish likely to be exposed to oil, and significant habitat downstream. Impact would vary depending on season when spill occurred.
[7] Disturbance to streambanks and resulting erosion is expected to be minimal to low in all cases.

TABLE 9.4-19 SUMMARY OF IMPORTANT IMPACTS TO SALMON AND TROUT IN WESTERN WASHINGTON

| IMPACT | CONSTRUCTION | | | OPERATION | | | ABANDONMENT | | | REMARKS |
|---|---|---|---|---|---|---|---|---|---|---|
| | Intensity | Duration | Magnitude | Intensity | Duration | Magnitude | Intensity | Duration | Magnitude | |
| SEDIMENT | Moderate at most stream crossings. Siltation from in-stream trench excavation. | 1 year or less. Generally until high flows flush sediment from gravel. | Several hundred feet downstream from crossing. | Moderate at stream crossings. Sediment influxes would occur during run-off from streambank erosion. | For the project life but decreasing at most crossings throughout project life. | Several hundred feet downstream from crossing. | Low at most stream crossings. Siltation from stream bank erosion Assumes pipe would remain in place under streams and minimal streambank disturbances would occur. | 1 year or less. Generally until high flows flush sediment from gravel. | Several hundred feet downstream from crossing. | Siltation of spawning areas would reduce fish production if sediment is in gravel when spawning occurs or is deposited while eggs are incubating. Worst-case would eliminate all fish production for several hundred feet downstream from crossing for 1 year. Siltation would also reduce insect production. Fish losses would not generally be noticed except possibly in certain river fisheries in severe cases. Siltation would result from streambank erosion as vegetation is removed and soil disturbances occur and as instream trenching occurs during the construction phase. Siltation would decrease at most stream crossings throughout project life as revegetation occurs. Siltation would also occur during the abandonment phase if soil is disturbed. Some populations may remain suppressed after abandonment. |
| | FUEL OIL SPILL | | | PIPELINE RUPTURE | | | FUEL OIL SPILL | | | |
| OIL SPILL | Low in most cases because of small volumes. | Duration of the spill in streams. | Several miles downstream from spill. | Moderate to high in most streams. | Impact would be for the duration of the spill. Several week residual impact in some streams. | Several miles downstream from spill. | Low in most cases because of small volumes. | Duration of the spill in streams. | Several miles downstream from spill. | Oil spills would reduce fish populations in all areas where high concentrations of oil occur. Worst-case could eliminate all fish which are exposed to oil. Fish would avoid oil concentrations where possible. Fish populations exposed to oil over a longer period of time would suffer higher mortalities. Oil-contaminated water could enter the Puyallup, and Issaquah salmon hatcheries downstream from the crossing area. All production in these facilities at the time of exposure could be lost. Full recovery of fish populations would occur after several spawning cycles. Fuel oil spills could occur during construction and abandonment phases from equipment operation. Pipeline rupture could occur during operation. |

runs 113 miles from the southern tip of Whidbey Island to Tacoma. Depths average 590 to 786 feet in this section but can occasionally be deeper. The southern Sound has numerous branching channels, inlets, and islands, The Nisqually River is the largest source of freshwater in the southern Puget Sound.

Hood Canal, averaging less than 2.5 miles in width and 590 feet in depth extends about 47 miles south-southeast from Admiralty Inlet and then turns more than 90 degrees to the east and continues another 14 miles. Dabob Bay branches off to the north from the middle of the canal and is approximately 11 miles long.

The movement of water within the Puget Sound-Hood Canal system consists of a three layer system similar to that in the Strait of Juan de Fuca. Tidal currents cause the back and forth oscillations of the water masses in addition to the energy required for both horizontal and vertical mixing. The presence of sills at the entrance of Hood Canal and in the southern Puget Sound Basin impedes the flow of deep water into these areas. This impeded flow increases the time required to replace or flush the water in these systems. The canal flushes slowly in part because of its tremendous length relative to its width. The mean replacement time is about 177 days (Vagner and Mar 1972).

Hood Canal, lacking industrialization, has a marine water classification of extraordinary or class AA. Water bodies in the South Puget Sound have various classifications. Oakland Bay, Totten Inlet, Budd Inlet, Eld Inlet, Pickering Passage, Peale Passage, Skookum Inlet, and Hammersley Inlet are classified as excellent or class A. This is principally because of inputs from forest industries and low tidal flushing (McGary and Linclon 1977). Waters in Budd Inlet, south of Priest Point Park, are classified good or B. All other inlets and bays in the South Puget Sound area are classified extraordinary or class AA, except Commencement Bay where waters are both excellent or A and good or B. Location of the various water classes can be found in the Map Addendum.

During construction along the western perimeter of Hood Canal and around South Puget Sound, no impacts can be expected on water quality.

A rupture in the pipeline at one of the stream crossings would significantly impact the water quality in Hood Canal or South Puget Sound since a large volume of oil could be transported from the aquatic environment to the marine environment. The estimated, existing pipeline risk in Greater Puget Sound, for a spill equal to or greater than 2.4 barrels, is one spill every 1.19 years. The estimated frequency of pipeline spill magnitudes for 198 statute miles of onshore pipeline from Port Angeles to North Bend around the Sound is given in table 9.4-20. An oil spill, equal to or greater than 2.4 barrels, for the alternative pipeline route would be one spill every 2.5 years. The combined risk is therefore estimated to be one spill, equal to or greater than 2.4 barrels, every 0.81 years. The impact of an oil spill upon water quality in Hood Canal or Puget Sound would be significant. Estimated mean flushing times are 177 days for Hood Canal and 56 days for Southern Puget Sound (Friebertshauser and Duxberry 1972).

Expressions of probability are useful indicators of future events, but caution must be taken to avoid misinterpretation of these estimated values. "One spill every 'X' years" expresses a calculated rate and does not indicate when the spill may occur. Also, the estimate will remain valid only if conditions do not deviate significantly from historical patterns.

TABLE 9.4-20 ESTIMATED FREQUENCY OF PIPELINE SPILL MAGNITUDES FOR 198 ONSHORE PIPELINE MILES FROM PORT ANGELES TO NORTH BEND
(Spills ≥ 2.4 Barrels)

| Spill Magnitude (in barrels) | Spill Frequency and Uncertainty 1/ (years per spill) |
|---|---|
| | Port Angeles 709,000 bbls/day and 933,000 bbls/day |
| | One spill every: |
| 2.4 - 10 | 6.7 years (3.3, - ) |
| 10.1 - 100 | 5.3 years (2.6, - ) |
| 101 - 1,000 | 20 years (10.0, - ) |
| 1,001 - 10,000 | 100 years (50, - ) |
| 10,001 - 100,000 | 1,000 years (333, - ) |
| A Spill ≥ 2.4 | 2.5 years (1.2, - ) |

Source: OIW 1978

1/ The ranges shown in parentheses are estimates of the 95 percent confidence limits based on the derived historical pipeline spill rates, and were calculated by assuming that the variance of each spill magnitude category was equal to the variance of the dta for all pipeline spills. Upper limits are unpredictable and indicated by a dash.

### Biological Components

Marine areas that might be affected by the pipeline are Hood Canal and South Puget Sound. These two areas support important commercial Pacific oyster and Olympia oyster fisheries and are suitable for oyster culture and oyster spawning. Commercial and sport bottomfish, salmon, shellfish, crab, and shrimp fisheries are also important in the areas (Washington State Department of Fisheries 1973a, 1973b, 1976; Washington State Department of Natural Resources 1977) (Washington Department of Natural Resources, 1977; Squire, Jr. and Smith, 1977). The distribution of bottomfish and salmon are those areas fished, indicating the areas where fish are concentrated.

Many marine fowl rest, feed, nest, and winter in numerous locations in south Puget Sound Basin. These waterfowl consist of plunge divers, divers, diving ducks, dabbling ducks, geese, and shorebirds. A particularly important waterfowl habitat is found on the Nisqually Flats.

Numerous mammal species are found in the inland waters of the Puget Sound Basin, south of Admiralty Inlet, and Hood Canal. These mammals are predominately harbor seals, porpoises, and river otters.

### Threatened and Endangered Species

Two endangered marine mammals, the gray whale and humpback whale, have been sighted in Puget Sound (Everit, Fiscus, DeLong 1979). The location of these sightings are shown in the Map Addendum. These whales are not common to the Puget Sound area;

hence, they should be considered strays from their usual outer coast migratory routes. No threatened and endangered marine birds are found within the southern Puget Sound Basin. Bald eagle sites can be found throughout the basin, but these birds are terrestrial species which frequently visit marine habitats.

No impacts to the marine resources in Hood Canal or south Puget Sound are anticipated due to construction of pipeline river crossings.

Pipeline ruptures on the Duckabush River or Skokomish River would impact harbor seal haul-out areas and river otter habitats in Hood Canal. A rupture on the Quilcene river would degrade water quality in Dabob Bay and could severly impact the Pacific oyster culture. Any pipeline rupture in a stream entering Hood Canal would result in tainting and sublethal effects in geoducks, butterclams, intertidal hardshell clams, shrimp, and crabs. Sports and commercial fisheries could also be affected. A major waterfowl area and harbor seal haul-out area at the Great Bend could be impacted causing high waterfowl mortality and/or low egg hatchabiity. Herring spawning grounds are located near the Duckabush River. If these grounds were impacted by oil during a spawning run, a year-class could be lost. This could have an indirect impact upon those fishes that feed upon herring.

An oil spill on the Nisqually River in South Puget Sound could impact the marine resources in the Nisqually Reach. These resources are intertidal clams, crabs, and shrimp. Also, Nisqually Flat is a major waterfowl area and river otter habitat.

### Terrestrial Vegetation

The Olympic Peninsula, including Green Point and the pipeline corridor to pipeline mile 75, is within the cedar-hemlock/Douglas-fir ecoregion. This forest land is one of the finest coniferous forests in the world; dominant species attain their maximum development (Franklin and Dyrness 1973). The corridor through the Olympic foothills includes a mixed conifer-deciduous forest interspersed with pastureland. Douglas-fir, western red cedar, and red alder, salmonberry, salal and juneberry occur in most areas including the BPA power-line corridor. Although this area has the most dense forest cover, most of these forests have been logged over so the stands are young.

The Willamette-Puget Forest ecoregion (pipeline mile 76 to 150) includes the Puget Trough physiographic province and has special plant communities. These communities include prairie vegetation and stands of lodgepole pine, western white pine, and ponderosa pine (Franklin and Dyrness 1973). Their presence reflects the different glacial history, climate, and soils of the area as compared to surrounding mountainous terrain.

In the western portion of this ecoregion lodgepole pine and Douglas-fir are major overstory components. Red alder, salal and big-leaf maple are dominant members of the shrub strata. Most of the remaining forestland is dominated by Douglas-fir, red alder, Oregon white oak, and western red cedar. Most of the forest has been logged.

The Mima, Weir, and Smith prairie habitats and pasture lands are also found in this ecoregion.

A major impact on natural vegetation from pipeline construction and normal operation would occur in the forested ecoregions, tables 9.4-21 and 9.4-22, which include the Olympic, and Cascade Ranges in western Washington. These conifer dominated plant communities would lose, for the life of the project, their overstory components. Estimates of acres of forest land cleared for construction for around Puget Sound segment of the pipeline are shown on table 9.4-21. These estimates are based on measurements made from photomosaics of the proposed route and assumptions that a 75-foot right-of-way would be permanently maintained in all cases.

TABLE 9.4-21 ACRES OF NATURAL VEGETATION IMPACTED

| Ecoregion | Pipeline Mile | State County | Construction (acres) Forestland | Maintenance (acres) Forestland |
|---|---|---|---|---|
| Cedar/Hemlock/ Douglas-fir Forest | | WASHINGTON | | |
| | 0-22 | Clallam | 203 | 169 |
| | 22-52 | Jefferson | 174 | 145 |
| | 52-75 | Mason | 115 | 96 |
| Willamette/ Puget Forest | 75-92 | Mason | 133 | 117 |
| | 92-128 | Thurston | 229 | 203 |
| | 128-159 | Pierce | 186 | 167 |

1/ Short-term = less than 1 year.
2/ Long-term = more than 1 year.
3/ + or - = nature of impact, negative or positive.
H = substantial or "significant" impact; M = moderate or almost "significant" impact; L - low or minor impact.

Forest land adjacent to the maintained corridor should not be significantly damaged by vegetation maintenance operations primarily because the applicant (NTPC) will not use aerial spraying of herbicides (Northern Tier Pipeline Company 1978).

The quantity of timber production which would be lost during the life of the project can not be estimated at this time because of insufficient information.

Associated with this loss of dominant overstory vegetation would be an expected increase in shrubs, grasses, and sedges, within the first year following construction. The species diversity of the pipeline right-of-way would increase, in that less shade-tolerant plants would have more suitable habitat.

These less shade-tolerant plants, predominately forbs and shrubs, are characteristic of early successional stages of plant community development. These plants, which could include juneberry, blackberry, and legumes, would not occur or would be less abundant in tHe more advanced successional plant community dominated by trees.

Other potential impacts on vegetation could occur at the crossings of the Hamma Hamma and Skokomish River Valleys where tidal and freshwater wetlands exist in the lowlands near Hood Canal.

The specific types of impacts on terrestrial vegetation resulting from oil contamination have been discussed in several publications (Baker 1971b, 1971c; Hutchinson and Freedman 1975; Schwille 1967; and others). The extent of impact resulting from a spill would primarily depend on the time of year and spill size.

### Threatened and Endangered Species

Although several threatened and endangered species probably inhabit the project right-of-way, no unique habitats are known to be within the corridor.

### Terrestrial Wildlife

Northern bald eagles are classified as threatened in the state of Washington. Active northern bald eagle nests, as well as inactive nests and wintering populations are identified in table 9.4-23.

Areas of special concern along the around Puget Sound segment of the pipeline are listed on table 9.4-24.

Impacts on wildlife from pipeline construction could include the following:

Abandonment of current breeding sites influenced by sensitivity to disturbance activities;

Removal of breeding adults from the general population through disturbance and alteration of normal feeding and reproductive behavior;

U.S. Forest Service

TABLE 9.4-23 LOCATION OF BALD EAGLES

| | | | | Habitat Descriptions and Observations | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | | | | Nest Sites | | Wintering Sites | | | | |
| Species | Total Numbers | Location | Pipeline Mile | Active[1/] | Inactive[2/] | Resident[3/] | Occasional[4/] | Season of Occurrence | Sightings and Activities | Sources |
| Bald Eagles | 4 | Washington Green Point | 0 | | x | x | | Winter | No nests identified. Two mature eagles sighted at proposed tank farm site. One mature and one immature eagle sighted along bluff near proposed tank farm site. Possible winter roosting habitat on Green Point. | ERT 1978 |
| Bald Eagles | Unknown | Dabob Bay | 34 | x | | x | | Winter and resident year-round | One nest 2 miles east of proposed pipeline was active in 1975. Eagles observed along southwest side of Bay and in general area during winter. | Washington Department of Game 1978 |
| Bald Eagles | Unknown | Quilcene Bay | 35 | | x | | x | Winter | Inactive nest in 1975. Observation of eagles along southwest side of Bay and in general area during winter. | U.S. Forest Service 1978 |
| Bald Eagles | 12 | Hamma Hamma River | 56 | | x | x | | Winter | Inactive nest in 1975. 10 eagles near river mouth sighted in one observation. Eagles frequently observed along this migration route from early fall through early winter. | Washington Department of Game 1978 |
| Bald Eagles | Unknown | Lilliwaup Bay | 64 | | x [5/] | | x | Not identified | Nest identified 2 miles south of Bay. Actual use not determined. | Washington Department of Game 1978 |
| Bald Eagles | 2-3 | Nisqually Delta | 127 | x | | x | | Winter and resident year-round | One eaglet produced in 1975 in nest 8 miles north of proposed route. Nest was inactive in 1976 and 1977. Total of 153 eagle observations from 1973-1977 in general area during late winter. | Washington Department of Game 1978 |
| Bald Eagles | 1 | White River | 158 | | x | | x | Unknown | No nests located. Good potential nesting and wintering area. | U.S. Forest Service 1978 |

Increased observation and predation of nest sites and adults and feeding areas;

Potential reduction of prey species and other food sources by alteration of habitats; and

Potential decrease of productivity caused by timing and duration of construction.

TABLE 9.4-24 AREAS OF SPECIAL CONCERN

| AREAS/STATE | WILDLIFE | PIPELINE MILES |
|---|---|---|
| WASHINGTON | | |
| Isabella Lake | Waterfowl concentrations downstream from Gosnell Creek crossing | 85 |
| Nisqually River | Winter waterfowl concentrations, important pheasant habitat and great blue heron | 128 |
| Puyallup River | Winter waterfowl concentrations | 144 |

Disturbance along the pipeline segment would affect both wintering and nesting northern bald eagles. Impacts to bald eagles would be the same as those discussed for wildlife on the pipeline in chapter 3.

Two active eagle nest sites could be impacted along the pipeline segment. The Nisqually River Delta nest site is approximately 8 miles north of the pipeline route. Eagles here could be impacted indirectly by an oil spill along the Nisqually River causing oil contamination of food items. Direct impacts from construction disturbances would be unlikely, but feeding habits could be disrupted. The nest near Dabob Bay is approximately 2 miles from the proposed route. Eagles here may abandon the nest site during construction activities. Bald eagle nesting along the pipeline segment have previously been indicated. Impacts on these eagles are described in table 9.4-25.

No pergrine falcon nests have been located in the corridor of the pipeline segment.

Impacts on other species of wildlife in areas of special concern are shown in table 9.4-26.

## Cultural Resources

The cultural resources sites listed below would potentially be affected if this route segment alternative is used. There is high potential for discovery of additional archaeological and historic sites along the proposed corridor, especially at crossings of stream valleys.

The currently known sites are shown in tables 9.4-27, 9.4-28, and 9.4-29.

Potential impacts to these sites and to any presently unrecorded sites would be the same as those discussed in chapter 3.

## Visual Resources

As this alternate route traverses around Puget Sound, the terrain is low, rolling foothills. The vegetation is coniferous cover. The northern foothills and shoreland are open farm and pastureland. Along Hood Canal, dense conifer forests have some deciduous trees in the drainages.

Many farms, homes, and rural developments are in the foregroung-middleground visual zone of the proposed corridor. They include the towns of Carlsborg, Sequim, Quilcene, Shelton, and developments around Lake Isabella, Summit Lake, and Black Lake plus several smaller communities. Much of this segment is also in the foreground-middleground visual zone of the U.S. Highway 101, a designated scenic highway, and of Sequim Bay and Dosewallips State Barks, the Skokomish Indian Reservation, and the Naval Auxillary Air Station in Shelton. It is in the middleground-background visual zone and visible from view-points enroute to Olympic National Park.

Overall, the portion of the route from Green Point to Black Lake has both high scenic quality (A/B) and visual sensitivity. It is in the visual managment quality class II (USFS Retention).

The portion of the route extending from Black Lake to North Bend, has a C scenic quality rating; visual management quality class III (USFS Partial Retention). Landform in the Puget Lowlands is level to rolling timberland. Vegetation is dense to scattered coniferous cover with some deciduous trees and understory in the open areas and drainages.

There are some scattered rural residential areas and open farmlands throughout the segment. Water features crossed by the proposed route include the Deschutes, Nisqually, Puyallup, Carbon, and White Rivers, along with several small streams and drainages. Man-made intrusions include high-voltage transmission lines cut through forest lands and many cleared blocks of timberland interspersed along the route. Because of these intrusions and the large open tracts of farmland and sparse population, this segment has a moderate to low sensitivity rating.

Analysis of the visual impacts of construction of the pipeline system assumed that:

Pump stations would be located on sites with a grade of 5 percent or less.

The proposed right-of-way would stay within the existing BPA corridor wherever possible.

The clearcut width of the BPA right-of-way corridor is over 600 feet in some areas and expansion is anticipated for upgrading and/or adding of new powerlines.

TABLE 9.4-25 SUMMARY OF IMPACTS ON BALD EAGLES

| Area | State | Pipeline Mile | Nesting Sites |  | Wintering Sites |  | Impacts |
|---|---|---|---|---|---|---|---|
|  |  |  | Active[1/] | Inactive[2/] | Resident[3/] | Occasional[4/] |  |
| Green Point | WA | 0 | X |  | X |  | Removal of winter and nesting habitat by destruction of roosts and disturbance of feeding areas. |
| Dabob Bay | WA | 34 | X |  | X |  | Eagles may abandon an active nest due to disturbance. |
| Quilcene Bay | WA | 35 |  | X |  | X | Intermittent use of an existing nest may be abandoned. Increased disturbance may displace wintering eagles and alter feeding and roosting habits. |
| Hamma Hamma River | WA | 56 |  | X | X |  | Intermittent use of an existing nest may be abandoned. Increased disturbance may displace wintering eagles and alter feeding and roosting habits. |
| Lilliwaup Bay | WA | 64 |  | X[5/] |  | X | Intermittent use of an existing nest may be abandoned. Increased disturbance may displace wintering eagles and alter feeding and roosting habits. |
| Nisqually Delta | WA | 127 | X |  | X |  | Eagles may abandon an active nest due to disturbance. Increased disturbance may displace wintering eagles and alter feeding and roosting habits. |
| White River | WA | 158 |  | X |  | X | Potential nesting habitat may be abandoned and breeding eagles displaced to areas of less disturbance. |

Sources: U.S. Fish and Wildlife Service; Washington Department of Game

[1/] Nest occupied and young may be produced.

[2/] No known nests near corridor; potential nest sites available; observations of eagles in general area.

[3/] Frequent observations of eagle populations from September through February.

[4/] Occasional observations during winter; occurrence of resident populations unknown.

[5/] Existing nest; production and occupancy unknown.

TABLE 9.4-26 POTENTIAL IMPACTS ON WILDLIFE IN AREAS OF SPECIAL CONCERN

| | | | IMPACTS | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | Construction | | Operation | | | | Abandonment | | |
| | | | | | Normal | | Worst-Case | | | | |
| Area | State | Pipeline Mile | Long-Term | Short-Term | Long-Term | Short-Term | Long-Term | Short-Term | Long-Term | Short-Term | Wildlife Impacts |
| Isabella Lake | WA | 85 | 0 | -L | 0 | -L | 0 | -M | 0 | -L | Waterfowl concentrations include approximately 49 birds per mile which disturbance or an oil spill could impact. |
| Nisqually River | WA | 128 | 0 | -L | 0 | -L | 0 | -M | 0 | -L | Summer months over 538 waterfowl while winter months reach 4,842 birds which could be impacted by disturbance and/or an oil spill on the Nisqually River. |
| | | | -M | -M | -L | -L | 0 | -L | 0 | -M | Construction could destroy all or part of a great blue heron rookery used by 12 to 15 pairs and disturbance could reduce production. |
| Puyallup River | WA | 144 | 0 | -L | 0 | -L | 0 | -L | 0 | -L | Winter concentrations of waterfowl could be impacted by an oil spill. |

Note: Construction, Operation, and Abandonment--assumes activities would occur during most sensitive period for the species impacted within the time frames.
Normal Operation: assumes right-of-way maintenance would occur every 5 years. Worst-Case Operation: assumes a maximum oil spill event would occur. Abandonment: assumes pipe would be removed. Long-Term: lasting more than 1 year or affecting more than one generation. Short-term: lasting less than 1 year or affecting only one generation. Significant Impacts: rated in magnitude as 0 (none), L (low), M (moderate), or H (high), and as + (beneficial) or - (adverse).

Waterfowl concentration U.S. Fish and Wildlife Service

When no unmanageable conflicts between construction and operation of BPA's existing and future facilities exist, BPA will consider joint right-of-way occupancy.

Clearing of a pipeline right-of-way requires removal of existing vegetation and exposure of the soil resulting in a significant visual impact. A swath through dense forest on steep slopes would contrast sharply with a previously undisturbed environment. Even with revegetation there would be moderate color and texture contrast with surrounding forest. Construction of an access road on steep slopes would produce high cut and fill embankments. Revegetation would be difficult, so the contrast of the exposed soil to the adjacent undisturbed vegetation would persist at least for the life of the project. In less scenic or more developed areas the contrast would be less noticeable.

TABLE 9.4-29 PALEONTOLOGICAL RESOURCES ALONG THE NTPC AROUND PUGET SOUND ALTERNATIVE

| County and State | Formation | Age | Type of Locality or Type of Sediment With Potential for Containing Fossils | Location by Pipeline Mile | Within or Crossed by 2-Mile Wide Study Corridor |
|---|---|---|---|---|---|
| Clallam, WA | Twin River | Oligocene-iocene | Marine sedimentary rocks | 0-15 | x |
| Clallam, WA | Twin River | Oligocene-Miocene | Fossil locality | 5 | Probably |
| Clallam, WA | Peat Bog | Younger-Quaternary | Mastodon and bison bones with human cultural material | 11 | x |
| Clallam and Jefferson, WA | Twin River | Eocene-Oligocene | Marine sedimentary rocks | 25-35 | x |
| Mason, Thurston, Pierce, and King, WA | Various | Younger-Quaternary | Glacial drift and till, and alluvium | 67-197 with a few minor breaks | x |
| Thurston and Pierce, WA | Skookumchuck | Eocene | Fossil locality | 127 | x |

Pump Stations

Four pump stations would be located along this route segment alternative of the pipeline. A forested site was chosen for a worst-case discussion of visual impacts.

Landform Modification. A 6 to 7 acre rectangular tract of land would be cleared and leveled. The color and texture of the exposed soil would contrast sharply with the dense coniferous forest setting.

Access Roads. The cuts and fills needed to form the road surface would also expose soil that would contrast in color and texture with the surrounding forest.

The pump stations would be devoid of vegetation and thus have high color and texture contrast with the dense forest cover of the surrounding environment.

The three-dimensional rectangular block cut out of the forest would become more obvious as the observer's angle of incidence increased. It would also create an unnaturally straight-line shadow form, and expose the contrasting color and texture of tree trunks on the uphill side.

The swath cut for the access road would leave a scar that would be observed as a straight linear form, contrasting in color and texture with the adjacent foliage.

Structures. The appearance of a pump station would contrast strongly with the forest setting. The linear form and color of the flattop tanks, square buildings, barbedwire topped chain link fence, and the angular metallic ancillary gear, piping, and fittings would accentuate the contrast.

Support Facilities. Each pump station would require a source of electric power and an electronic receiver for remote control. In mountainous terrain, signal reflector dishes would be needed for microwave transmission; most sites would be on high, prominent points and most would require a road for construction and maintenance. Construction of access roads, powerline rights-of-way, and reflector dish sites through forestland would accentuate the visual intrusion. The high color contrast of the exposed cut and fill embankments for the road and its surface would in most cases exceed the maximum allowable contrast for visual management Class II and would cause severe adverse visual impacts.

In relatively flat, open field, seldom-seen areas, such as farmland, prairie, and grasslands, the contrast of a pump station and its component parts would be high. However, the site would usually be rated Class III in the visual resource management system, because few people would see it.

Major oil spills, breaks, or leaks in the pipeline during the operation phase could cause adverse impacts to visual resources by contaminating widespread areas, especially shorelines, rivers, and tributary streams.

Contaminated water surfaces would adversely impact water color and quality. The resulting kill of fish and vegetation lining the banks and shorelines would be another significant adverse visual impact.

Cleanup operations to entrap, burn, or physically remove contaminated soil, cobble or vegetation would leave the shoreline or streambanks barren. Repair of the leak would require exposure of the subsoil and the pipe, with impacts similar to construction.

Modifications in the natural form, line, color, and texture would persist for at least 2 years, and diminish over the life of the project.

This alternate to the proposed route is in two sections, the first from Green Point to Black Lake, the second from Black Lake to North Bend. The first, in the visual resource management system is judged to be class II - with a scenic quality rating of B, the second is class III - C.

It is assumed the proposed pipeline route would stay within the EPA existing right-of-way wherever possible, however, there are portions of this segment in which the proposed pipeline would occupy its own right-of-way.

As described in the general remarks on construction, the clearing and alteration of the land for maintenance roads and for installation of the pipeline would create contrasts that would be adverse visual impacts in this highly scenic and visually sensitive segment. Construction would impact the view of motorists at the crossing of the pipeline route and U.S. Highway 101, south of the tank farm at Port Discovery and Jackson Cove, and at hillside cuts as seen from Sequim Bay and Hood Canal. At all of these critical observer positions, maximum allowable contrast for visual management quality objective Class II would be exceeded, and visual resources adversely impacted. As the route crossed the highway a clearcut corridor through the timber would be observed by travelers. This would have high visual impact during construction and could remain as a moderate impact beyond the life of the project.

The contrast created by the crossing of the Dungeness, Dosewallips, Duckabush, Hamma Hamma, and Skokomish rivers would exceed the visual management quality objectives during construction, but would not persist. Revegetation of the riparian landscape would soften the construction impacts, hence, the visual management quality objectives would be met. Pump station 2 is assumed to be located in an open cleared area and so should not have any adverse visual impact.

Almost half of the proposed route would parallel other rights-of-way. The pipeline could expand those existing corridors, but would have far less impact than cutting a new swath through dense forestland.

A good portion of the remaining half would traverse forest lands, some agricultural lands, small communities, and subdivisions. The project would cause moderate visual contrast which would persist for the life of the project. For the rest of this segment, contrast would be low, hence the pipeline construction would meet the visual quality objectives and would not constitute an adverse visual impact. However, the swath through dense timber for the new right-of-way would persist for the long term. The crossing of Interstate 5 would be in the foreground visibility zone of users of this scenic highway--an adverse visual impact.

The crossings of the Nisqually, Puyallup, Green, and Cedar rivers would cause moderate to high visual impact during construction. With the revegetation of disturbed banks, the persisting contrast should be moderate to low.

## Land Use

The primary impact of the around Puget Sound pipeline segment and its ancillary facilities on land use would be the conversion of existing uses to the proposed project use for 20 years. Certain land uses including most cultivated crops and forage production can co-exist with the pipeline and associated uses. Other uses such as timber production or intensive uses involving improvements cannot co-exist.

Certain project features preclude other uses. For the pipeline system, those would include pump stations, remote block valves, electric substations and communication sites. Additional land areas would be needed for such purposes as storage yards, borrow pits and, spoil disposal. An unknown amount of land would likely be needed for borrow and spoils disposal during construction. The storage yards averaging about 12 acres each would be located along railroad sidings or other similar open areas. Utility lines, like the pipeline itself, would impact all types of land uses.

### Urban

From Green Point to the intersection with the proposed route the pipeline corridor passes near numerous urban fringe areas. Dominant land uses are agriculture and forest-woodland, however, residential land use commonly occurs in these areas at relatively high densities.

Since the pipeline would be constructed near numerous urban fringe areas, construction would cause nuisance impacts of noise, dust, travel delays, and visual disharmony for brief periods that should not exceed 2 weeks in any one locale (assuming a 1/2 mile per day construction rate).

Pipeline system operation should result in no significant impact to urban lands, in view of the secondary uses that can be made of the right-of-way such as open space, greenbelt areas, recreation buffers or utility corridors.

### Agricultural

Agriculture is a significant land use within the corridor consisting primarily of improved pasture and truck farming, most often located near river floodplains. Individual land holdings are often small, frequently in the range of 5 to 80 acres.

Approximately 400 acres of prime farmland are within the 2,400-acre right-of-way segment. This represents approximately 17 percent of the around Puget Sound right-of-way segment.

Although federal criteria have been established for identification and designation of prime and unique farmlands, mapping has not yet been accomplished. Therefore these data are based only on the soils criteria.

Construction would generally result in the loss of one year's crop on agricultural lands crossed by the around Puget Sound segment of the pipeline. One year's crop loss would generally occur because most of the crops grown within the corridor require a full year's growing season. Construction would take place from April through November progressing at a rate of about one-half mile per day. After construction, the soil disturbance and compaction might lessen productivity for a few years depending upon soil conditions, trenching method, and restoration measures. The losses in agricultural production would not be significant in terms of local (county) agricultural production. Productivity might also be decreased by disturbances of drainage systems. Subsurface drainage systems are particularly sensitive since they are difficult to replace properly once disturbed. There are subsurface drainage systems along the route in Thurston, Pierce, and King Counties.

Normal operation of the pipeline system should have few significant adverse impacts on existing agricultural land uses, except for those areas occupied by block valves from which agricultural use would be displaced. This would not represent a significant amount of agricultural land within any one locale.

An oil spill occurring on agricultural land might ruin a portion of one year's crop and decrease productivity for 1 to 5 years following the spill, if reclamation is effective. The impacts of an oil spill on agricultural land are discussed in the land use section 3.

### Rangeland/Open Space

Rangeland and open space lands are not significant in terms of their extent within the around Puget Sound corridor. Generally such lands consist of flood plains, unimproved and unirrigated pasture, and cleared forest and brush lands.

Pipeline system operation across rangeland and open space should have few impacts except for those areas occupied by block valves. The areas occupied by block valves would be excluded of forage production for the life of the project.

Livestock operations could be adversely impacted as discussed in the land use section of chapter 3. The impacts of an oil spill on rangeland or open space are discussed in the land use section of chapter 3.

### Forest/Woodland

Significant amounts of forest and woodland are within the corridor of this segment of the pipeline. These lands consist of small privately owned woodlots and large corporate-owned and publicly owned forestland. Almost all of the forest land crossed by the corridor in the Puget Sound region is considered commercially productive.

Within the permanent pipeline right-of-way, and at pump stations 1, 2, 3, and 4, timber production would cease for the 20-year life of the project.

In addition, electric transmission lines to serve the pump stations would remove additional forest and woodlands from production. In terms of productive forest land within the affected areas, the impact does not appear to be significant. Forest lands might benefit from cleared rights-of-way serving as fire breaks or fire protection access. Realization of this possible benefit would be highly dependent on the right-of-way location. Conversely, the pipeline location would limit where forest management roads could be layed out

### Native American Areas

The around Puget Sound segment of the pipeline would be located immediately adjacent to and would parallel the west boundry of the Skokomish Reservation for a distance of 3 miles. The adjacent reservation lands are, for the most part, forested. In addition, the pipeline corridor is located within approximately 8 miles of the Nisqually Reservation in Thurston County, and the Muckleshoot Reservation in King County. Native Americans of the Pacific Northwest Region also have fishing rights in areas outside of reservations.

Pipeline construction around Puget Sound might adversely affect areas used by Native Americans for fishing.

Normal operation and maintenance impacts across Native American areas would be similar to those incurred by the land uses described above.

### Natural and Scientific Areas

These are areas in which natural features are preserved for scientific or educational purposes. The Washington State Marine Atlas references numerous sites on Hood Canal and southern Puget Sound that are used for scientific research.

Pipeline construction would not be apt to cause any direct impact to established natural or scientific areas, however construction activity on relatively undisturbed areas would destroy their value for future natural or scientific use.

In Thurston County, Black River Swamp, Millersylvania State Park, and Weir Prairie are being considered for inclusion in the National Registry of National Landmarks. These areas might be impacted by pipeline construction.

Normal operation and maintenance should not cause significant impacts to existing natural and scientific areas although it might preclude the establishment of new areas.

It does not appear likely that an oil spill would impact any natural or scientific areas.

### Wilderness

The around Puget Sound pipeline corridor does not cross any U.S. Forest Service RARE-II Study areas that have been recommended for wilderness designation or allocated for further planning.

Neither pipeline construction nor operation will impact any U.S. Forest Service RARE-II wilderness study areas.

### Land-Use Plans and Zoning

Local land use plans most often describe policies and goals. Seldom do they specifically address utility corridors. Zoning resolutions generally allow utilities in most zoning categories either by right or through a permitting process. It is therefore often a matter of interpretation whether a particular action would be consistent with existing plans and regulations.

Prior to the cross-sound route change, the Energy Facility Site Evaluation Council (EFSEC) determined that the proposed pipeline would be consistent with applicable plans and zoning within the state of Washington. Their findings, however, did not encompass regulations contained in County Shoreline Master Programs, which would be determined later in the permitting process. The NTPC application to EFSEC prepared by Environmental Research and Technology (ERT 1978) found that the pipeline would be inconsistent with Shoreline Master Program regulations in Pierce County at crossings of the South, Voight, Wilkeson and South Prairie Creeks unless automatic shut-off valves are provided on both sides of these crossings.

Where the pipeline corridor crosses Federal lands in Washington, it is subject to U.S. Forest Service management plans. These plans generally require that linear rights-of-way follow existing corridors whenever feasible. Additionally, they contain provisions designed for resource protection.

In general pipeline system facilities would not tend to seriously constrain land-use plans and zoning since virtually all other types of land uses could occur within reasonable proximity to the facilities.

## Transportation and Utility Networks

### Inland Water Transportation

This segment of the pipeline runs parallel to Hood Canal for many miles in western Washington (roughly pipeline miles 34 to 75). The canal is a major natural inland waterway for pleasure boating, commercial and sport fishing, and shellfish gathering. River transportation near the proposed river crossings is limited to recreation-related traffic.

Navigable waters are crossed at locations where there is no significant commercial traffic. Construction impacts are unlikely, although recreation related boating activity might be impacted.

Normal operation of the pipeline system should cause no adverse impacts to inland water transportation.

An oil spill into rivers and streams tributary to Hood Canal and southern Puget Sound would not be likely to transport sufficient quantities of oil into these waterways to have significant impact on transportation activities.

### Railroads

Fifteen major railroads would be crossed by the proposed pipeline. Three major railroads would be paralleled for 10 miles. There may be a limited number of additional crossings of spur lines and unidentified private rail lines.

The possibility of adverse impacts to railroads would occur at the crossings and parallel rights-of-way stated above. Since all railroad crossings would be tunneled, the impact to rail traffic should be limited to possible speed restrictions lasting for 1 week or less through the construction areas. Rail traffic slow downs might be of longer duration where construction is parallel to the railroad through areas confined by topography or other improvements.

Railroads would haul some of the construction materials. Storage yards would generally be located along railroad sidings where the pipe and other materials could be stored. Railroads generally have excess capacity so transporting construction materials would not be likely to cause any adverse impact to rail service.

Normal operation would cause no significant adverse impacts to railroads.

An oil spill within a railroad right-of-way might cause impacts similar to those discussed in the transportation and utility section of chapter 3.

### Roads and Highways

Two Interstates and 14 primary federal and state highways would be crossed along the proposed pipeline corridor.

The secondary road network from Green Point to near Olympia (approximately the first 100 miles of pipeline) is limited by topography and low population. Roads are few and tend to follow the rivers flowing into Hood Canal. In the Puget Sound lowlands (to about pipeline mile 190), the more abundant roads follow a somewhat modified grid pattern. Much of the pipeline route is roughly parallel to and relatively close to major highways and connected to outlying areas by county roads which would be crossed by the pipeline. The more numerous roads in the non-mountainous and more populated areas generally provide reasonable alternative connections between places. The county roads near towns and the numerous other municipal streets and roads which would be crossed when the pipeline would skirt the larger towns carry a substantial amount of local traffic.

The existing road network of federal and state highways, paved and unpaved county roads, unimproved roads, and BPA and other utility access roads would provide access to the pipeline construction corridor along the entire route. Along most of the route, away from towns and cities, these access roads carry quite low volumes of traffic.

In early 1979 the Hood Canal Bridge collapsed during a storm. The bridge, with a 1976 average daily traffic count of 4,977 (Washington State Highway Commission 1976) was a connecting link between Kitsap and Jefferson Counties. The bridge closure is expected to result in higher traffic volumes on U.S. Highway 101. Such a traffic increase might affect the amount of congestion and traffic delays due to pipeline construction-related activities near the highway.

Heavy truck traffic would probably cause some road damage at locations where such traffic would be concentrated near storage yards and pump stations. Weight estimates indicate that approximately 1,200 tons of equipment and materials would be required to construct each pump station.

Construction of permanent access roads to pump stations would require 1 mile or less each. The new permanent access roads are not likely to be significant in any area.

Temporary access roads would be needed at intersections of deeply incised drainages, where pipe stringing trucks (and perhaps other equipment) would not be able to follow the right-of-way. These roads would generally be less than 1 mile in length, and would not appear to significantly impact road and highway networks.

Impacts might occur where the pipeline would cross or be located adjacent to existing roads and highways. Impacts due to construction, operation, and in the event of an oil spill would be similar to those discussed in the transportation and utility section of chapter 3.

Airports

Eight commercial airports, military air bases, and other airfields are located along the pipeline route. There may be additional small landing strips along the route.

Although pipeline construction could occur adjacent to several airports it is not likely any significant impacts would occur. Planned facility expansion at Shelton airport and runway expansion at the Olympia airport would not appear to be affected by the around Puget Sound pipeline corridor. Possible construction impacts to air navigation facilities would be similar to those discussed in the transportation and utility section of chapter 3.

Under normal pipeline operation, inspection flights of the pipeline would be made every 2 weeks. These flights might penetrate the airport traffic areas of one airport with commercial service and smaller general aviation airports. At Olympia, Washington, the inspection flights would pass in the immediate vicinity of the airport with commercial service and substantial (25,000+ operations yearly) traffic.

Electric Transmission

The proposed pipeline corridor would cross 12 major transmission lines and parallel 9 other transmission lines for 147 miles. Where the pipeline route parallels a powerline any crossings that might occur would not be determined until final survey and design were completed. In urbanized areas, there would be many local distribution lines which could be crossed by the pipeline. The location of such crossings would not be known until obtained from local utility offices at the time of detailed land surveys. In rural areas there would be many crossings of distribution lines that frequently parallel roads along township and section lines. The location of these crossings would also be determined when land surveys were carried out.

The pipeline system would require construction of additional transmission lines as shown in table 9.4-30.

In addition to the transmission lines shown in the table distribution lines would be constructed to some block valves and possibly to some communications sites. Construction of new transmission and distribution lines would impact land uses. There is no indication that utilities would be adversely impacted by this level of construction.

The increased electric loads required for and induced by construction would be negligible. The potential for physical damage to transmission lines and utility access roads exists at each of the crossings and along the adjacent or shared right-of-way.

Impacts due to the construction and operation of the pipeline are similar to those discussed in the transportation and utility section of chapter 3.

An oil spill upon the shared or adjoining 147 miles of right-of-way would be of concern because of the resultant vegetation loss, fire hazard, and risk of damage to electrical transmission facilities during pipeline repair. The frequency of oil spill is estimated to be one spill in 2 years.

TABLE 9.4-30 NEW ELECTRICAL SYSTEM FACILITIES REQUIRED IF THE PROPOSAL IS IMPLEMENTED

| Pump Station1/ | Serving Utility | New Transmission Facilities | Estimate of New Right-of-way Area Required |
|---|---|---|---|
| 2 | Mason County PUD | 1/4 mile 230 KV line | 6 acres |
| 3 | Puget Sound Power & Light | 2 miles 115 KV lines | 24 acres |
| 4 | Puget Sound Power & Light | 4 miles 55 KV rebuilt to 115 KV | ---- |

Sources: BPA 1978 Western Area Power Administration 1978; ERT 1978

1/ Pump station 1 is included with the onshore storage facility.

Shared, and to a lesser extent, adjacent rights-of-way would have positive impacts since less right-of-way clearing would be required, existing access roads could be used, visual impact would be reduced, and other impacts would be confined within a similar geographic area.

Communications

In urbanized areas there would be many crossings and much construction parallel with underground and overhead communication lines including telephone and cable TV. The exact numbers and locations of these facililities would not be known until final survey and design were completed.

Outside the urban areas the pipeline parallels an American Telephone and Telegraph (AT&T) cable operated by Pacific Northwest Bell.

Impacts due to construction, operation, and in the event of an oil spill are similar to those discussed in the transportation and utility section of chapter 3.

Unaffiliated Pipelines

Six various types of pipelines would be crossed along this segment. In addition, the route would parallel two existing pipelines for 25 miles. When a shared route is narrow and constricted by topography there might have to be multiple line crossings which cannot be precisely located at this time. In local urbanized areas, many natural gas, water, sewer, and storm sewer pipelines would be crossed. The locations of these smaller local pipelines would be obtained from the local private and municipal utility offices at the time of detailed land surveys.

The possibility of construction damage to other major pipelines would occur at the six crossings and along 25 miles of adjacent or shared right-of-way. The significance of this unlikely, although possible, impact would depend on the type of pipeline damaged and the location and extent of the damage.

### Recreation

The section from Green Point to Olympia, Washington, experiences heavy recreational use of its shoreline, adjacent Olympic National Forest, and Olympic National Park.

The type, magnitude and degree of impacts to recreationists and recreational use areas are, in general, similar to those associated with the proposed cross-sound preferred route segment.

Construction and abandonment activities would primarily affect tourists, pleasure drivers, and those requiring access to destination points on the Olympic Peninsula. Use of U.S. Highway 101, the only direct road to Port Angeles, would be congested during construction activities. This would affect a significant, however unknown, number of individuals who require access to the Olympic National Forest or Olympic National Park; who participate in day use activities along the Hood Canal, or who are tourists bound for Port Angeles, Washington, or Victoria, British Columbia. Highway congestion is compounded by the 1979 loss of the Hood Canal bridge.

In the vicinity of the proposed corridor there are numerous campgrounds, trails, picnic, and wayside park areas. Two state parks, Millersylvannia and Nolte, are crossed by the corridor. U.S. Highway 101, which provides easy access to a variety of recreational areas in the Olympic National forest and Olympic National Park is heavily used by recreationists. Recreational use of shoreline state parks along Hood Canal and the southern portion of Puget Sound accounted for about 25 percent of all state shoreline park usage in 1978. The use of state shoreline parks is considered to represent a small portion of all recreational use of marine areas. Intensity of use in these areas is approximately the same as for Central Puget Sound, the area crossed in the Northern Tier proposal. According to 1977 Salmon Punch Card Data, 10 percent of the total marine sport salmon catch in Washington was taken from the southern portion of the Puget Sound area including Hood Canal during an estimated 187,500 marine salmon angler trips (Washington Department of Fisheries 1977). Important river recreational salmon fisheries are found in the Dosewallips, Duckabush, Hamma Hamma, and Skokomish Rivers. Patterson, Crocker, Tarboo, and Leland Lakes are freshwater lake recreational fishing areas. Bottom fishing in the Tacoma Narrows is considered to sustain an excellent catch. Overall, recreational bottomfishing in Hood Canal and the southern portion of Puget Sound captures about 50 percent of the total Strait, Sound, and coast catch. Shellfish harvest is an important recreational as well as commercial activity in the Canal.

Eighty percent of the recreational shellfish catch in Puget Sound is from Hood Canal (SRI 1978). Based on a 2-year average of recreational use data, approximately 220,000 recreational user trips occur each year in Hood Canal. Scuba diving often complements sport shellfish collection. Other diving activity occurs in established underwater parks. These are designated areas known for underwater interest and may feature historic shipwrecks or unique rock or coral formations.

Both the Skokomish and Green Rivers are considered to have high scenic and recreational values by the State of Washington. A pipeline crossing would conflict with Washington State management guidelines as defined in the 1971 Washington State Shorelines Act. In addition, the corridor along the Green River from Kummer Bridge site to Kanasket was designated in 1969 by state legislation as the Green River Gorge Conservation Area. The proposed pipeline would cross this area just downstream from Kanasket and along the border of the Jellum State Park site. The noise from construction activities and visually changed character would detract from use of the adjacent Jellum State Park site for the duration of the project.

Both Millersylvannia State Park and Nolte State Park are within the two mile corridor; however no facilities are located in the areas crossed. Impacts would consist of visual intrusion of the corridor for the life of the project and noise harassment for the short term (less than 1 month). Nolte State Park is considered part of the Green River Gorge Conservation area.

Normal operation would not affect most recreational use. Off road vehicle use of the right-of-way and access road would probably occur.

An oil pipeline leak could affect the shellfisheries and shoreline park use along Hood Canal. An average of 220,000 recreationists participate in shellfish collection along Hood Canal each year. Contamination of all beds for the estimated in four year shellfish bed recovery period could affect a minimum of 880,000 recreationists. Shoreline parks along Hood Canal had over 3 million visits in 1978. Oil contamination beach areas would be unuseable for one to two months and could affect a minimum of 400,000 to 800,000 recreationists (assuming 1 month loss of use) if a pipeline break occurred between June and August.

A worse case pipeline rupture and leak along Hood Canal would not affect as many recreationists as a worse case submarine pipeline break between Port Williams and Point Partridge. The lack of flushing mechanisms would create a longer term and more severe local situation along Hood Canal from the same size of pipeline leak.

Other uses which would be affected for the short term include marine fishing, boating, and river fishing of the Dungeness, Dosewallips, Duckabush, Hamma Hamma, and Skokomish Rivers.

## Social and Economic Conditions

### Population

The population of Clallam, Jefferson, Mason, Thurston, Pierce, King, and Kittitas Counties, and the number of peak construction period work force are provided in table 9.4-31. Due to the relatively brief period during which peak construction demands would occur, no significant impacts would be created by the estimated work force and associated persons on the existing population. Work force estimates for the operation phase would not significantly affect population projections.

### Infrastructure

According to a study prepared by SRI International, there will be ample housing for the estimated peak construction period work force population except in Mason County where housing availabilities would be strained (1978).

Due to the relatively short period of peak construction in the various counties no significant impacts would be expected to occur on public utilities, school systems, medical services or police and fire protection services.

## TABLE 9.4-31 SOCIAL DATA FOR COUNTIES ADJACENT TO AROUND PUGET SOUND ROUTE SEGMENT

| County | Type* | Land Area (sq. miles) | 1977 population | Density (Persons /sq. mile) | Annual Growth rate 1970-1975 | Projected Population 200 | Projected Annual Growth Rate 1977-2000 | Medical Facilities | | | | Estimated Peak Workforce Construction |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | | | | Hospitals city/beds | | Intensive care unit | No. of Personnel | |
| Clallam | R | 1,753 | 41,100 | 24 | 3.54 | 55,900 | 1.35 | Forks | 2 | x | 62 | 539 |

### Social Well-Being and Quality of Life

Negative effects on indicators of the quality of life would occur from implementation of the proposed alternative. During construction rural landowners would have to adjust to construction activities. Their life styles would be altered temporarily. Construction activities with associated noise, dust, and traffic pattern changes would affect residential perceptions of the aesthetic setting, quality of air, and the region "as a place to live" during the construction phase. However, these would not be significant adverse impacts.

The proposed pipeline route would involve counties in which seven Indian reservations are located. In Clallam County these are the Makah, Lower Elwha Tribal Community, and the Quileute. Mason County includes the Skokomish and Squaxin reservations. The Nisqually reservation is in Thurston County, and the Puyallup reservation is in Pierce County.

These tribes oppose implementation of the alternative maintaining that potential oil spills would adversely affect their fishing enterprises.

## CUMULATIVE IMPACTS: POTENTIAL TO SUPPLY PUGET SOUND REFINERIES

Construction of the crude oil transportation system using the around Puget Sound segment would make possible an alternate method of supplying 350,000 bpd of crude oil to four existing refineries located on the east side of Puget Sound. These refineries are presently being supplied by tankers. Development of this supply would require actions by both NTPC and others.

### Tanker Unloading Facilities

NTPC would be required to expand the Port Angeles port and onshore storage fcility to accommodate the additional 350,000 barrels per day throughput. Increased tanker calls per year would also be required such as 395 port calls per year for the 933,000 barrels per day increased to 511 port calls per year for 1,283,000 barrels per day throughput. The description of the action required by NTPC has been presented in the section on Cumulative Impacts: Potential to Supply Puget Sount Refineries in chapter 6, Environmental Analysis of the Action at Port Angeles. Oil spill risk and fire and explosion data are also presented.

### Pipeline System

In order to provide 350,000 bpd of crude oil to the four Puget Sound refineries, the intial 198 miles of the proposed pipeline, from Green Point to North Bend, Washington, would be used. The proposed 42-inch pipeline would have the capacity for the increased throughput of 1,283,000 bpd, but pump station arrangements would need to be modified. Three new pump stations would be required in addition to the three which are proposed along the 198-mile segment.

If the need to provide the 350,000 bpd throughput for the Puget Sound refineries was determined prior to intial operation and in time to redesign the initial 198 miles of the pipeline system prior to the beginning of construction, only five pump stations would be required instead of the six listed above.

The expanded pipeline system would also require delivery facilities with approximately 2.1 million barrels of storage capacity near North Bend. From that delivery facility some company other than the Northern Tier Pipeline Company would be responsible for construction of a pipeline segment to connect North Bend to the existing Trans Mountain Pipeline System near Burlington, of approximately 1 million barrels of operating tankage near North Bend and approximately 500,000 barrels of tankage at Burlington.

Table 9.4-32 shows the results of the oil spill risk analysis for pipeline spills with the increased throughput.

The risk of fire damage at pump stations is another potential adverse effect which is greater with the increased throughput. Table 9.4-33 presents the results of the fire risk analysis for the 198-mile segment from Green Point to North Bend.

TABLE 9.4-32 ESTIMATED FREQUENCY OF PIPELINE SPILLS
(For throughputs of 1,059,000 bpd and 1,283,000 bpd,
Green Point to North Bend, plus North Bend to Burlington)

| Spill Magnitude (in barrels) | Spill Frequency and Uncertainty 1/ One Spill Every: |
|---|---|
| 2.4 - 10 | 4.8 years (2.2 - ) |
| 10.1 - 100 | 3.6 years (1.7 - ) |
| 101.0 - 1,000 | 14.3 years (6.7 - ) |
| 1,001.0 - 10,000 | 50.0 years (33 - ) |
| 10,001.0 - 100,000 | 500.0 years (250 - ) |
| Any spill ≥ 2.4 | 1.7 years (0.8 - ) |

Source: OIW 1978

1/ The ranges shown in parentheses are estimates of the 95 percent confidence limits based on derived historical pipeline spill rates, and were calculated by assuming that the variance for each spill category was equal to the variance of the data for all pipeline spills. Upper limits are unpredictable and indicated by a dash.

TABLE 9.4-33 ESTIMATED FREQUENCY OF FIRE DAMAGE AT PROPOSED NTPC PUMP STATIONS 1/
(For throughputs of 1,059,000 bpd and 1,283,000 bpd - Green Point to North Bend)

| Fire Damage Magnitude | Fire Frequency and Uncertainty 2/ One Fire Every: |
|---|---|
| $ 1,000 - $ 10,000 | 65 years (45-95) |
| $ 10,000 - $100,000 | 105 years (80-155) |
| $100,000 - $500,000 | 255 years (190-380) |
| over $500,000 | 1,660 years (1,250-2,470) |
| Any fire ≥ $1,000 | 33 years (25-49) |

Source: OIW 1978

1/ For fires causing damages greater than $1,000.

2/ The ranges shown in parentheses for each fire damage magnitude category are estimates of the 95 percent confidence limits, and were calculated by assuming that the variance of each fire damage magnitude category was equal to the variance of the data for all fires.

## COEUR D'ALENE

This alternate route segment was originally the proposed pipeline route across a part of the state of Idaho. The route passed north of the city of Coeur d'Alene and crossed for a significant distance (25 miles) over the Spokane-Rathdrum Aquifer. The ground water from this aquifer serves a large public demand for the major cities of Coeur d'Alene, Idaho, and Spokane, Washington, as well as the surrounding rural agricultural area. Following the Northern Tier Pipeline Company announcement of the pipeline route across the Spokane-Rathdrum Aquifer, public and government opposition developed to potential oil contamination. The U.S. Environmental Protection Agency officially designated the aquifer as a "Sole Source Aquifer" (February 1978). That designation prohibits action on projects that would create a potential hazard to public health. Consequently, NTPC developed a new pipeline route to avoid the aquifer. The description and environmental analysis of the Coeur d'Alene route segment is presented in the following discussion.

### Description

The Coeur d'Alene alternate departs from the proposed route near Spangle, Washington, travels northeast and then passes south of the city of Spokane, crossing the Spokane River and then east across the Washington-Idaho State boundary (fig. 9.4-9). The route then proceeds north of the city of Coeur d'Alene, paralleling a powerline right-of-way through the Idaho Panhandle National Forest and joining the prime route near Kingston, Idaho, adjacent to Interstate 90, for a total distance of 85 miles.

### Climate and Air Quality

No impacts on climate are anticipated for this alternative pipeline route.

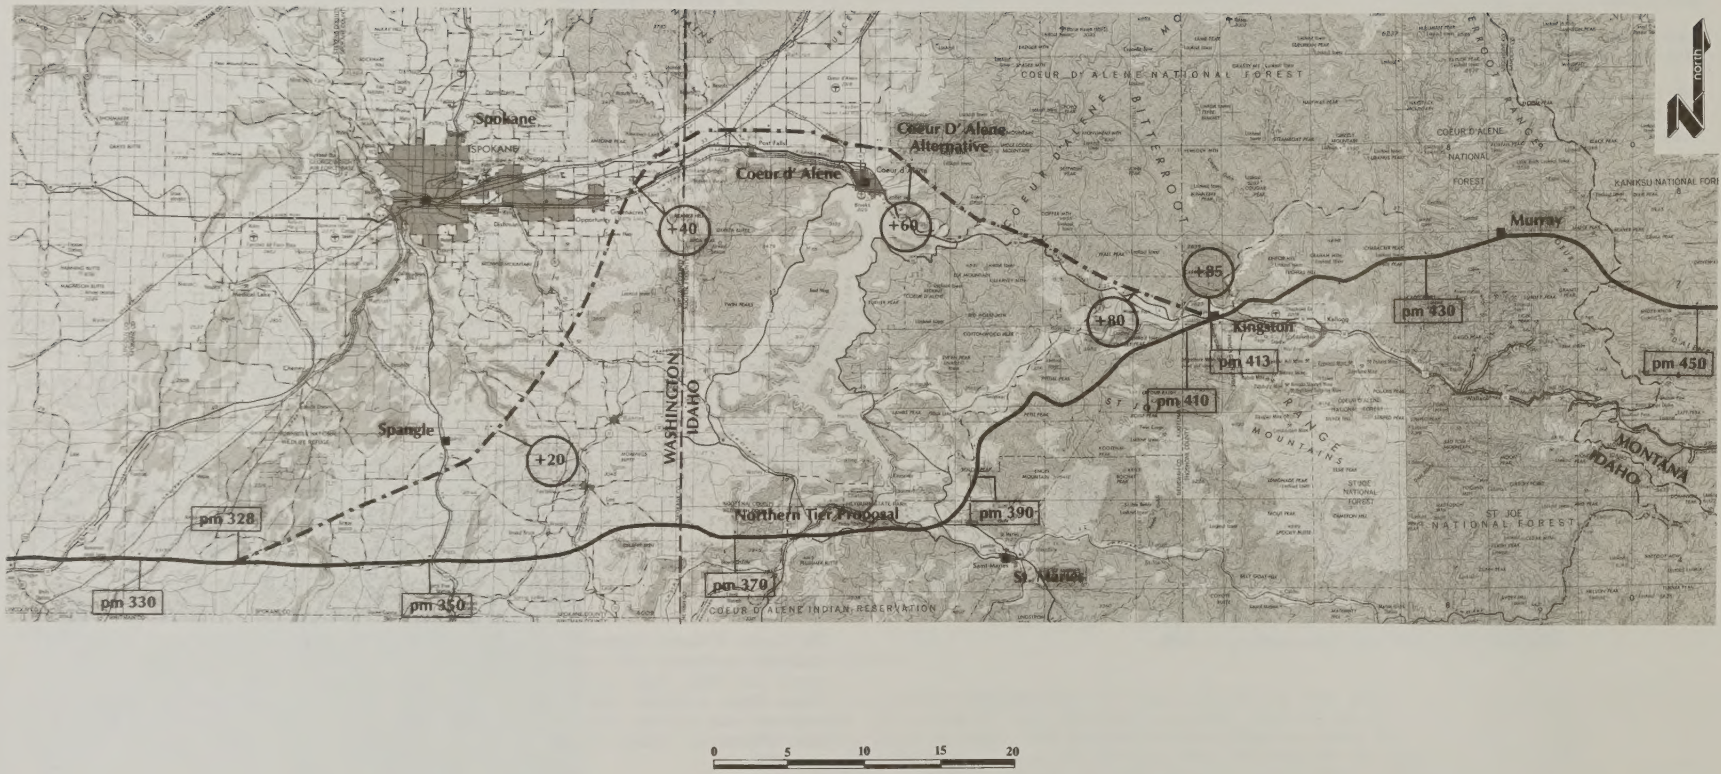

Figure 9.4-9

Northern Tier Pipeline Company

Coeur d'Alene
Route Segment Alternative

Air quality impacts would be similar to those for the other alternative route segments.

## Noise

Noise impacts associated with pipeline construction and operation would be similar to those for the other alternative route segments. Some residential areas east of Spokane, Washington, and in Coeur d'Alene, Idaho, would be affected by construction noise.

## Topography and Geology

This route segment alternative is characterized by rolling hills and lakes, the broad, nearly flat Spokane Valley and the moderatley steep Coeur d'Alene Mountains. While similar to the proposed route between pipeline mile 335 and Cataldo Mission (pipeline mile 410) the terrain is less steep and topographic impacts, consiting of minor landform changes and short-term drainage alterations, would be less severe than along the proposed route.

Geologic material, consisting of Quaternary glacial debris, windblown silt (loess), alluvium, lower Tertiary volcanic rock, and Precambrian sedimentary/metasedimentary rocks, is similar along both routes. Consequently geologic impacts, which would consist of the removal of large volumes of geologic material and some excavation-induced (including blasting) alterations of the physical characteristics (e.g., permeability, porosity, and inherent rock strength), would be essentially the same.

Like the proposed route, this route segment alternative is in an area of moderate seismic activity corresponding to a Seismic risk Zone 2 (moderate earthquake damage expected). As neither route would encounter active or potentially active faults and both routes have experienced similar levels of seismic activity, the anticipated impacts from surface fault rupture and ground shaking would be the same.

Potential slope instability problems (landslides and/or liquefaction) are more numerous along this route segment alternative—Coeur d'Alene alternate pipeline miles 0 to 28, 30 to 32, 34 to 39, 58, 60, and 68 to Cataldo Mission (proposed route pipeline mile 410). Consequently, anticipated impacts are expected to be greater.

## Mineral Resources

Based on available information, there is no significant difference in impacts to mineral resources.

## Soils

Deep silt loam soils are evident from Spangle, Washington, to the Spokane River and constitute about 30 percent of the route segment. The section is part of what is known locally as the "Palouse Hills Country." The soils are highly susceptible to wind and water erosion.

From the Spokane River and across the Spokane Valley to Coeur d'Alene the principal soils are Garrison loam and gravelly loam. These soils, which constitute about 35 percent of the route, occur on nearly level to gently rolling slopes. They are characterized by gravelly, stony surfaces and rapidly permeable subsurfaces. The remaining part of the route traverses mountain ridges and valley side slopes of the Coeur d'Alene mountain range. The soils are moderately deep, medium textured and rocky on steep and very steep slopes.

The major impacts on soils would be erosion from water and wind when the right-of-way lacked protective vegetation. Much of the route between Spangle and Spokane River lies across farmland with normally high erosion rates. Soil losses from water erosion are often as much as 70 tons per acre on steep slopes in a single season. Average losses on cropland in this area are 10 to 12 tons per acre per year (Idaho-Washington RCD Project 1964). After construction, similar rates would be expected. Wind erosion on unprotected soils in this area would be about 15 tons per acre per year, assuming unprotected distances of 1,000 feet. Since half of the cropland is normally fallow each year, impacts attributed to pipeline construction would be 50 percent less than for noncropland.

Erosion losses would be less severe in the Spokane Valley where slopes are more gentle and the soils are gravelly. Unprotected soils would lose an estimated 2 tons per acre per year as compared to 0.05 tons per acre per year that would be expected with grass cover.

Severe impacts from erosion would occur in the mountainous area after removal of the forest vegetation and the surface litter. Normal losses of 0.40 tons per acre per year would increase to 30 tons per acre per year during construction. Revegetation with native grasses and shrubs would reduce those losses to about 2.0 tons per acre per year.

Impacts from soil compaction and profile mixing would be similar to those expected on the proposed route. A loss of about 5 percent of productive capacity would be expected. The impact from compaction would not be apparent after 2 years. Loss of fertility from profile mixing would be permanent.

Impacts from potential oil spills would also be similar to those on the proposed route.

## Aquatic Resources

### Physical Components

One major and approximately 24 minor streams would be crossed by the Coeur d'Alene alternative route segment. The only major river crossing would be the Spokane River. This river generally has seasonal variation of discharge with low flow periods usually occurring in August or September and maximum flow anticipated between March and May. Stream flow is controlled somewhat by storage in Coeur d'Alene Lake. Water quality classification for the Spokane River by the state of Washington (WAC 173-201) is class A indicating excellent quality water.

The Spokane-Rathdrum aquifer consists of unconsolidated glacial deposits which have a high capacity to store and transmit large quantities of water (Drost and Seitz 1978). The U.S. Environmental Protection Agency designated the Spokane-Rathdrum Prairie aquifer a "sole source" aquifer in February, 1978. Consequently, Federal assistance for any project that "may contaminate the aquifer through a recharge zone so as to create a significant hazard to public health" is prohibited by law. The aquifer is the principal public source of drinking water for individual wells, and public water supplies in Kootenai County, Idaho, and Spokane County, Washington.

Construction and operation of the pipeline would impact surface and ground water resources. Short-term increases in suspended solids would occur at and downstream of the river crossings. Construction during the August-September low flow period would minimize the impact. Trenching activities over the Spokane-Rathdrum Prairie aquifer would probably allow sediment laden waters to percolate to the water table, especially near the Spokane River crossing, causing short-term water quality degradation. Hydrostatic test water could be withdrawn from the Spokane River. Withdrawal during low flow periods could reduce river flow by as much as 10 percent. Normal operation of the pipeline would have no major adverse impact on water sources. However, in the event of a pipe rupture, oil would impact both surface and ground water causing water quality degradation. At the Spokane River crossing, the pipe would be laid within the aquifer. A leak would cause crude oil to seep into the aquifer at a point about 2 miles up gradient of three public supply wells. Relatively low concentrations of oil would render the water unsuitable for municipal consumption. Refer to chapter 3, Physical Components, for a more detailed discussion of impacts.

## Biological Components

Rock Creek, Spokane River, Blue Creek, and Wolf Lodge Creek are the major streams supporting fishery resources along this route segment alternative. Rock Creek supports a rainbow trout fishery and the Spokane River supports rainbow, brook and cutthroat trout, whitefish, perch and small-mouth bass. Significant trout spawning habitat occurs at the Spokane River crossing. Blue and Wolf Lodge Creeks provide spawning and rearing habitat for kokanee and lakerun cutthroat. Trout and kokanee populations would be reduced by spawning gravel sedimentation from instream trenching activities during construction and streambank erosion during project operation. Most of the sediment from instream trenching would be washed out of the spawning gravel during the first period of high flow, but sediment arising from streambank erosion would continue for several years until complete revegetation occurs. The greatest reduction to trout and kokanee populations would occur during construction and for the first few years of project operation. Several spawning cycles would be required for these reduced populations to recover to preproject levels; most populations should recover in a few years. The initial population reductions could fall below the normal range of population fluctuations and consequently would be evident. In subsequent years as revegetation occurred and erosion decreased, fish numbers would begin to return to the normal range of population fluctuations.

Fish populations would be reduced by an oil spill during project operation. An oil spill on Blue or Wolf Lodge Creek would probably reach Coeur d'Alene Lake where it would cause substantial fish losses. Several spawning cycles would be required for the reduced fish populations to recover to prespill levels.

Since fewer streams supporting fish populations would be crossed and fewer streams tributary to Coeur d'Alene lake would be crossed in this alternative route segment, the overall potential impacts to fisheries resources would be less than those associated with the proposed route.

Refer to chapter 3, for a more detailed analysis of fisheries impacts.

### Terrestrial Vegetation

Most of the vegetation impacted by construction of the proposed pipeline is associated with conifer forest. Trees, including hemlock, grand fir, and Douglas-fir, averaging 60 years old with a density of about 2,000 per acre, could be lost (U.S. Forest Service 1978). Younger and older trees and other species would also be impacted. This alternative would impact 5.2 miles and 57 acres of National Forest and would result in an annual loss of approximately 4,845 cubic feet of potential timber productivity (U.S. Forest Service August 1978). The shrub-forb vegetation that would become established after construction could improve habitat through increased diversity, browse production, and increased lower vegetative cover.

The long-term impact would be positive in forested areas, at least for some vegetation and wildlife, especially deer and elk, because more browse would be available from the shrubs-forbs and small trees permitted to remain established on the right-of-way. The short-term impacts on agricultural vegetation could depend substantially on time of construction Long-term impacts should be minimial.

The impacts on vegetation and wildlife from abnormal operation--specifically an oil spill--would be substantial.

At this time there are no known state or federally designated threatened or endangered plant species that would be significantely impacted by construction of this route segment.

### Terrestrial Wildlife

Bald eagles winter at the Wolf Lodge Bay area within 0.4 miles of the alternate route (table 9.4-34). The population varies between 40 and 70 from late November to mid-March (Lint 1977). The area is influenced by human disturbance, bordered by Interstate 90 on the north and Idaho Route 95A to the east and south. Known white-tailed deer wintering areas, used from December to March, are located along the north shore of the Coeur d'Alene Lake in the vicinity of Wolf Lodge Bay and along Wolf Lodge Creek, Blue Creek, Alder Creek and east along the corridor to the Fourth of July Summit.

White-tailed deer Bureau of Land Management

TABLE 9.4-34 WILDLIFE IMPACTS FOR THE COEUR D'ALENE ALTERNATIVE

| State | Endangered Species | Other Species | Season | Location | Impacts |
|---|---|---|---|---|---|
| Spangle, Washington<br>Coeur d'Alene, Idaho | Bald eagles 40-70 | | Late-November to Mid-March | Wolf Lodge Bay area 0.4 miles from alternative | Disturbance of roosting and nesting bald eagle areas<br>Line-of-sight visibility of construction activities<br>Possible synergistic effect from disturbance of Interstate 90 and Highway 95A and increased human influence from pipeline construction activities<br>Potential elimination of a stable bald eagle population |
| Spangle, Washington<br>Coeur d'Alene, Idaho | | White-tailed deer | Winter range December to March | North Shore of Coeur d'Alene Lake in vicinity of Wolf Lodge Bay and along Wolf Lodge Creek, Blue Creek | Increased browse production<br>Removal of thermal cover<br>Increased vehicular access<br>Increased harvest pressure |
| Spangle, Washington<br>Coeur d'Alene, Idaho | | Elk | Winter Range | North and East sides of Coeur d'Alene River from Enaville 8-10 miles up river | Removal of thermal cover disrupting movement, distribution and level of possible use; alteration of successional stages of vegetation used for browse |
| | | Waterfowl | Nesting and staging areas winter and summer | Mission Flats area | Destruction of riparian habitat<br>Marsh drainage<br>Disturbance of staging and nesting waterfowl areas |

## Cultural Resources

The cultural resource sites listed below would potentially be affected by this route segment alternative. Of the known sites the Mullan Road has been designated as a National Historic Civil Engineering Landmark, the Wagner-Dydball Grist Mill and the Cataldo Mission are included in the National Register of Historic Places and a segment of the Mullan Road in the Fourth of July Summit area on national forest lands has been nominated to the National Register. There is high potential for discovery of additional archaeological and historic sites all along this route segment alternative. The currently known sites are shown on table 9.4-35.

Potential impacts to these sites and to any presently unrecorded sites would be the same as those discussed in chapter 3.

## Visual Resources

The first two-thirds of this segment traversed by the pipeline is generally open farmlands and passes through small community developments and rural areas. Pipeline construction should have a moderate to high visual impact initially and decrease to the low range during the operation phase. Pipeline construction through the forested remaining portion of this section will require the clearing of a 90-foot right-of-way visible from several points along Interstate 90, which the alignment would parallel. This would cause an adverse visual impact persisting for many years.

## Land Use

This alternative route segment would have slightly greater land use impact because it crosses developing urban fringe areas, numerous small landholdings and irrigated lands between Spokane, Post Falls, and Coeur d'Alene. Nuisance impacts during construction, and the impacts which might result from an oil spill, as described in chapter 3, would be slightly more severe on this route than through the less intensively developed areas along the proposed route. Construction activity would require the use of approximately 120 acres more land than the proposed route with about 70 acres additional land area required for permanent right-of-way outside of existing rights-of-way (assuming that only 50 feet of additional right-of-way would be needed along existing corridors). This route avoids crossing the Coeur d'Alene Indian Reservation.

## Transportation and Utility Networks

The potential for adverse impacts to transportation and utility systems would be higher than for the proposed route because there are more crossings and an additional 55 miles where pipeline construction would be parallel and adjacent to existing roads, railroads, and unaffilitated pipelines.

Existing roads and highways provide good access for construction and fewer miles of access road would be needed during pipeline construction.

The electrical power demands and potential impacts to regional power supplies are comparable to the proposed route.

TABLE 9.4-35 CULTURAL RESOURCES FOR THE COEUR D'ALENE ALTERNATIVE

| County, State | Site Number | Site Name | National Register | Site Type | Location By Pipeline Mile |
|---|---|---|---|---|---|
| Washington | | | | | |
| Spokane | | Mullan Road | National Historic Civil Engineering Landmark | 19th century military, commercial 2nd settlement history | 1-10 |
| Spokane | | Wagner-Dydball Grist Mill | Yes | 19th and early 20th century architecture and industry | 8 |
| Spokane | 45SP30 | Bradford-Kennedy Mill | No | Early 20th century lumber industry | 46 |
| Idaho | | | | | |
| Kootenai | 10KA6 | | No | Prehistoric campsite | 65 |
| Kootenai | | Mullan Road | Portions nominated | See above | 69-85 |
| Kootenai | 10KA49 | Mullan Tree | Nominated | Historic monument | 75 |
| Kootenai | 10KA39 | | No | Prehistoric occupation site | 83 |
| Kootenai | 10KA3 | | No | Prehistoric campsite | 84 |
| Kootenai | 10KA1 | | No | Prehistoric campsite | 84 |
| Kootenai | 10KA45 | Cataldo Mission | Yes | 19th century mission | 84 |
| Kootenai | K0KA57 | | No | Historic homestead | 84 |
| Kootenai | 10KA43 | | No | Prehistoric campsite | 84 |

## Recreation

Kootenai County is considered the recreational center for the region (SRI 1978). Weekend tourist and local use draws from the Spokane and Silver valley areas.

Lake Coeur d'Alene is locally and regionally important for sport kokanee salmon and trout fishing as well as other water-related recreation. A pipeline leak or rupture affecting ground water and streams flowing into the lake would affect a significant, although unknown, number of recreationists. Hunters and wildlife viewers could experience a decrease in satisfaction if game left the area during the construction and abandonment phases. Congestion and activities along Interstate 90, which the Forest Service considers to be a scenic travelway, would affect those recreationist seeking day use destination points along the highway or along the Coeur d'Alene River. Construction or abandonment activities cross over four miles of national forest in the Fourth of July Summit area (U.S. Forest Service 1978) and may affect the Mullan Tree site (pipeline mile 75) and Mullan Road (pipeline miles 69-85). During 1977, 1,500 visitor days use occurred at the Mullan Tree, a site which accommodates only 20 people at one time.

As compared to the proposed route, this alternate would impact a greater number of recreationists.

## Social and Economic Conditions

Counties affected by this alternative would include Spokane in Washington and Kootenai and Shoshone in Idaho. The impacts would be similar to those resulting from the proposed route. A discussion of those impacts is found in chapter 3 of this report.

Impacts on population, housing, and community infrastructures would be low and short-term, ending when the construction was complete. Fire departments are largely volunteer and would be strained by a major fire. Benefical impacts would result from increased assessed valuation and property taxes. This alternative would completely avoid the Coeur d'Alene Indian Reservation and Benewah County, so the tribe and the county would not receive the economic benefits that they would accrue from the proposed route.

# COEUR D'ALENE RIVER

This Coeur d'Alene River alternative was examined by the Northern Tier Pipeline Company as an alternative to the proposed route. From Kingston, Idaho, (pipeline mile 413) to Delta (pipeline mile 430), the proposed pipeline route along Jackass Ridge would have one underwater crossing. This alternative route segment would have 12 Coeur d'Alene River crossings. The following description and environmental analysis compares this alternate route segment to the proposed route along the Jackass Ridge.

## Description

The Coeur d'Alene River alternative originates near Kingston, Idaho (pipeline mile 413), then follows the Coeur d'Alene River, southeast along Beaver Creek to Delta joining the proposed route west of Delta, Idaho, at pipeline mile 430 (fig. 9.4-10). This alternative would be a total distance of 23 miles compared to 17 miles for the proposed route.

## Climate and Air Quality

No impacts on climate are anticipated for this alternative pipeline route.

Air quality impacts would be similar to those for the other alternative route segments.

## Noise

Noise impacts associated with pipeline construction and operation would be similar to those for the other alternative pipeline route segment. Only scattered residences would be located in the vicinity of the pipeline route.

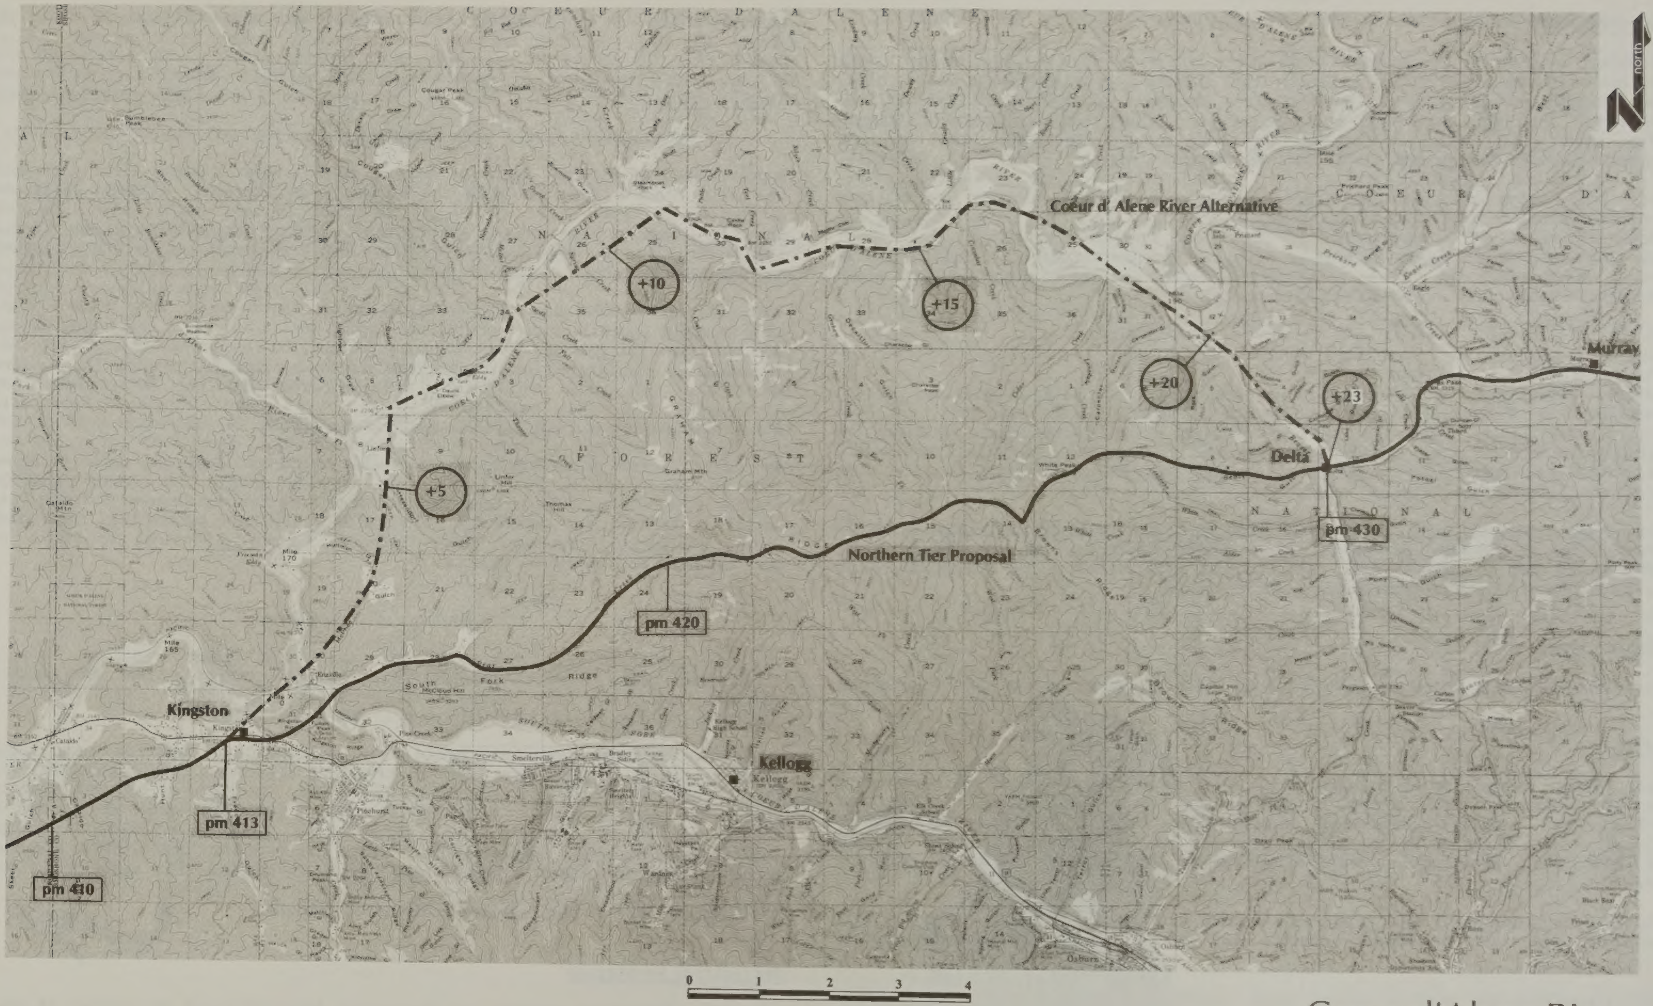

Figure 9.4-10

Northern Tier Pipeline Company

Coeur d'Alene River
Route Segment Alternative

## Topography and Geology

In marked contrast to the proposed route which follows a ridge for most of its length and has only one major stream crossing, this route segment alternative would follow the steep-walled valley of the Coeur d'Alene River and would involve 12 major river crossings. Much more excavation would be necessary along this route segment alternative which would result in substantially more acreage disturbed. The resultant impacts would be much greater than along the proposed route.

While both routes would encounter Precambrian sedimentary/metasedimentary rocks, this route segment alternative would encounter, in addition, Quaternary alluvium along the Coeur d'Alene River. The presence of this loose material, as well as the steeper terrain, would result in the excavation of a much greater volume of geologic material than along the proposed route. Consequently, impacts to the geologic material would be greater along this route segment alternative.

### Geologic Hazards

Although both routes would be within an area of moderate seismic activity, corresponding to a Seismic Risk Zone 2 (moderate earthquake damage expected), and have experienced similar levels of seismic activity, this route segment alternative would cross both steeper terrain and more easily liquefiable material (Quaternary alluvium). Consequently, the potential impacts from seismic activity would be much greater than along the proposed route.

Although no locations have been identified along either route showing slope instability problems, the steeper slopes and looser geologic material along the Coeur d'Alene River would seem to indicate that the potential impacts from slope instability would be much greater there than along the proposed route.

### Mineral Resources

No significant difference in impacts to the mineral resources has been identified.

## Soils

This 23-mile segment would traverse stony silt loam, and stony loam soils occurring on steep mountainous side slopes, ridges, and undifferentiated alluvium of the Coeur d'Alene River. Major impacts would occur in the form of soil erosion on the steep slopes. Soil losses up to 70 tons per acre per year would occur on slopes stripped of vegetation. Revegetation would reduce losses to less than 2 tons per acre per year.

Pipeline construction on the steep side slopes would require extensive cut and fill earthwork and would permanently disturb many acres of undisturbed forest soils.

Soil compaction and profile mixing would result in impacts consistent with those expected to occur on the proposed route. An estimated 5 percent of soil productivity would be lost. Soil compaction would not be apparent after 2 years. A permanent loss of natural fertility would result from profile mixing.

Impacts from potential oil spills would also be consistent with those of the proposed route.

## Aquatic Resources

### Physical Components

Approximately 22 streams would be crossed by the Coeur d'Alene River alternative. The Coeur d'Alene River would be the largest river crossed. Seasonal variation of streamflow is typical. Low flow periods occur in late summer; high flow can be expected in spring with snowmelt and rainfall. Some heavy metals, copper, iron, and lead, have been found in the Coeur d'Alene River. Water can be characterized as calcium-magnesium sulfate type.

Several impacts would occur from construction and operation of the pipeline. Cumulative sediment and siltation impacts would occur during and for a short time following construction. Various heavy metals would probably be resuspended and/or dissolved as a result of disturbance of the contaminated bed sediments causing toxic effects. Hydrostatic test water would probably be withdrawn from the Coeur d'Alene River. Withdrawal could reduce baseflow by 15 percent if taken during mean flow periods. Normal operation would not have a major adverse impact.

An oil spill from pipe rupture could degrade water quality. Oil would be released into the Coeur d'Alene River and if not contained within 1 day would reach Coeur d'Alene Lake. Coeur d'Alene Lake is a recharge area for the Spokane-Rathdrum Prairie Aquifer. This aquifer received a sole source designation by the U.S. Environmental Protection Agency in February, 1978. Refer to chapter 3, Physical Components, for a more detailed discussion of impacts.

### Biological Components

The Coeur d'Alene River, the major river supporting fishery resources along this alternative route segment, provides spawning and rearing habitat for cutthroat, rainbow, brook, and Dolly Varden trout, whitefish and kokanee. Fish also use the river as a migration corridor and spawn in the tributaries.

Reductions to these populations would occur as a result of spawning gravel sedimentation which would come from instream trenching activities during construction and from streambank erosion during project operation. Recovery of reduced populations would take several years. Reductions to fish populations would also occur downstream from an oil spill site if one should occur. Recovery of these reduced populations would also take several years. An oil spill in the Coeur d'Alene River would probably flow into Coeur d'Alene Lake where substantial fish kills could occur.

See chapter 3 for a more detailed analysis of impacts.

## Terrestrial Vegetation

For this alternative segment the vegetation impacted would be similar in species composition. The proposed route would impact about 121 acres of forestland with high productivity potential compared with 41 acres impacted by this alternative segment.

The impact on riparian vegetation resulting from construction of this alternative should be substantially greater than that resulting from construction of the proposed route on Jackass Ridge. This greater impact would be due to the 12 Coeur d'Alene river crossings. However, riparian habitat, dominated by cottonwood and willow, are common vegetation components in the area.

No endangered or threatened species are known to occur within this corridor.

## Terrestrial Wildlife

Deer and elk winter range occurs on the south and west-facing slopes and in the bottoms along the Coeur d'Alene River (see table 9.4-36 for impacts to wildlife). About 0.9 mile of winter habitat on national forest would be crossed on this alternative (U.S. Forest Service 1978).

## Cultural Resources

The known cultural resource sites which would potentially be affected by this route segment alternative are listed in table 9.4-37.

There is high potential for discovery of additional archaeological and historical sites all along this route segment alternative. Potential impacts to the known sites and to any presently unrecorded sites would be the same as those discussed in chapter 3.

TABLE 9.4-36 WILDLIFE IMPACTS ALONG THE COEUR D'ALENE RIVER ALTERNATIVE

| | Endangered Species | Other Species | Season | Location | Impacts |
|---|---|---|---|---|---|
| Kingston Coeur d'Alene River | None | White-tailed deer & elk | Winter | South and west facing slopes and in the bottoms along the Coeur d'Alene River | Increased browse production<br>Removal of thermal cover<br>Increased vehicular access and harrassment<br>Increased harvest pressure |
| | | Black bear and mountain lion | year-round | Potential habitat throughout the area | Potential displacement<br>Increased harvest pressure<br>Increased vehicular access<br>Decreased area for spatial mobility (home range for males is about 12 square miles) |
| | | Waterfowl | | Along tributaries of Coeur d'Alene River | No key waterfowl areas are expected to be impacted |

TABLE 9.4-37 CULTURAL RESOURCES SITES

| State County | Site Number | Site Name | National Register | Site Type | Location by Pipeline Mile |
|---|---|---|---|---|---|
| Idaho | | | | | |
| Shoshone | 10SE206 | Linfor Townsite | No | Early 20th Century town | 5 |

| | 10SE1 | Chinese ovens | No | | 14 |
| | — | Big Jam Administrative Site | No | Forest service history | 14 |
| | — | — | No | Historic structure | 21 |

### Visual Resources

This route entails 12 crossings of the Coeur d'Alene River. This is accomplished by following the Coeur d'Alene River route, but placing the alignment in gullies and on the hillsides of this forested, scenic, and visually sensitive area. The 90-foot wide right-of-way required for construction would require cuts and fills, construction roads, plus block valve sites. Even using the minimal width of 50 feet for the right-of-way, cut and fill slopes and the 30x60 foot cleared areas for the block valve sites, the resulting impacts created by the exposed areas as seen from the state secondary highway that traverses the bottom, somewhat paralleling the proposed pipeline route, would exceed the Visual Resource Management Objectives for Class II and III, and hence, constitute a severe adverse visual impact. This would persist many years beyond the life of the project.

Abandonment involves removal of the pipeline, block valves, and ancillary equipment; cosmetically recontouring the cuts and fills to blend with existing landform, seeding, and planting to endemic vegetation. A minimum of 20 years would be required for regrowth to return this section to Class II.

### Land Use

The impacts to land use would not be significantly different from those described in chapter 3. Although less productive forest lands would be lost (U.S. Forest Service 1978), more intensive agricultural, recreational and residential uses along the river would be disturbed.

### Transportation and Utility Networks

Although there would be several additional road crossings, traffic disruptions during construction would probably be similar to those described for the proposed route in chapter 3, or only slightly more since about 14 miles (55 percent) of the construction activity would be away from public roads.

Likewise, there would be more likelihood of construction caused damage to the Yellowstone petroleum products pipeline which is paralleled for about 7 miles. Impacts to electric power supplies and systems should be essentially the same.

### Recreation

Degradation of portions of the Coeur d'Alene River resulting from pipeline crossings and possible pipeline ruptures would affect all water related recreational activities for the short term. Fishing success and desirability in the Coeur d'Alene River and tributaries would be impacted during the construction and abandonment phases.

In addition picnicking, considered one of the most popular recreational activities in Idaho (Bureau of Outdoor Recreation 1973), together with pleasure driving, and berry picking would be directly impacted by the loss of favorite roadside stops and the general disturbed, noisy, and congested conditions along the construction route. These impacts in some areas would continue until vegetation was reestablished; in other scenic areas, the visual and vegetative loss or change would be permanent, and these activities would no longer occur. Construction trucks and activities would diminish the quality and use of the Coeur d'Alene River road which is considered a scenic travelway by the U.S. Forest Service.

The attractiveness of the pipeline corridor to off road recreational vehicles would encourage additional use and possibly affect other recreational users. Due to the high recreational use of the river corridor, this alternate route segment would affect significantly greater numbers of recreationists than the proposed route. See Map Addendum for locations of area recreational resources.

### Social and Economic Conditions

Counties affected by this alternative would include Kootenai and Shoshone in Idaho. The impacts would be similar to those resulting from the Coeur d'Alene River Alternative. A discussion of those impacts is found in chapter 3.

Impacts on population, housing, and community infrastructures would be low and short-term, ending when the construction was complete. Fire departments are largely volunteer and would be strained if a major fire were to occur. Beneficial impacts would result from increased assessed valuation and property taxes.

## DRIVEWAY RIDGE, MT.

The Driveway Ridge route segment represents an alternative to the Prospect Creek proposed route between Thompson Pass and Thompson Falls, Montana (figure 9.4-11).

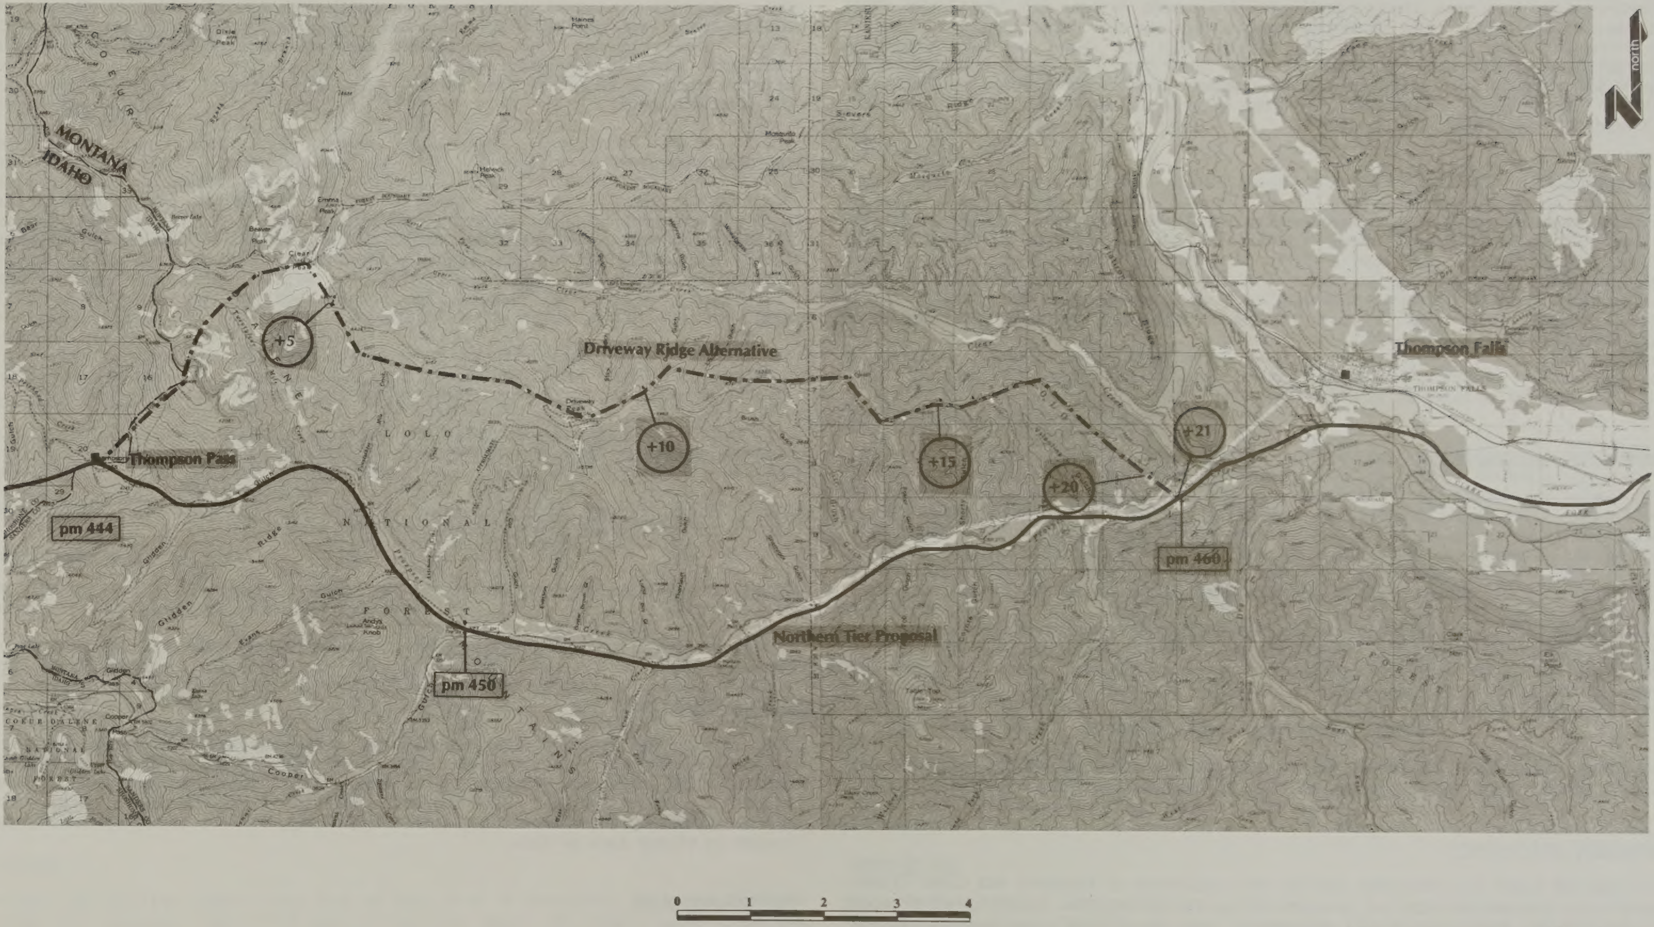

Figure 9.4-11

Northern Tier Pipeline Company

Driveway Ridge
Route Segment Alternative

This alternative departs from the proposed route (pipeline mile 444.2) near Thompson Pass, follows up a ridge northward, and then east along Driveway Ridge along Forest Service Road No. 7649. The firebreak (that extends east from the road) along Driveway Ridge has been cleared and widened from 90 feet to 200 feet for a total distance of 6.0 miles. The route then continues along the ridge top and descends to the Prospect Creek proposed route at pipeline mile 460 above the Clear Creek and Prospect Creek confluence. The Driveway Ridge route lies entirely on National Forest System land and is 20.6 miles long. The Prospect Creek route crossed 13.0 miles of National Forest System land and 3.4 miles on private and state land for a total distance of 16.4 miles.

## Description

This alternative starts at Thompson Pass on the Idaho-Montana border. From there it follows the state line north about 3.5 miles to the head of Twenty Four Mile Creek climbing 1,600 feet in the first 2 miles. Then the route turns east crossing Beaver Peak and then following the gradually descending Driveway Ridge to a point about 1 mile above the confluence of Prospect Creek and Clear Creek. Then the route turns south, dropping 1,400 feet in about 1 mile and rejoins the Prospect Creek route at pipeline mile 460.

The approximate length of this alternative is 20 miles, while the Prospect Creek segment which it replaces is 16 miles long.

## Climate and Air Quality

No impacts on climate are anticipated. Air quality impacts for this alternative would not differ significantly from those of the original proposal described in Chapter 3.

## Noise

This alternative would probably require an additional pumping station which would have an operating noise level of 69 dBA at 100 feet (approximately equivalent to the noise level experienced by a pedestrian on a city sidewalk when a car passes by). However, the pumping station would be in a remote location where very few people would normally hear it.

The impact of construction noise would be reduced because this segment would be built along a remote ridge top mostly two to three miles from the nearest house.

## Topography and Geology

The proposed route from Thompson Pass to the confluence of Prospect and Clear Creeks, would cross the valley floor of Prospect Creek (including five crossings of Prospect Creek and seven crossings of side drainages) compared to this route segment alternative which would be entirely on high ground with no drainage crossings. Since no river or stream crossings would be involved, topographic impacts along this route segment alternative would consist of widening of existing roads and trails and construction of about 2.5 miles of new road. Overall, topographic impacts would be less on this alternative route than on the proposed route.

The proposed route would cross easily excavated Quaternary alluvium whereas this route segment alternative would cross hard Precambrian sedimentary/metasedimentary rocks. While blasting would be required along portions of the route, most of the excavation would be generally limited to a 8 x 5-1/2-foot trench. As excavation in alluvial material requires wider trench walls, more material would be removed along the proposed route.

### Geologic Hazards

Both routes are located in an area of moderate seismic activity, corresponding to a Seismic Risk Zone 2 (moderate earthquake damage expected). However, neither route would encounter active or potentially active faults, nor have any large magnitude earthquakes (6+ on the Richter scale) occured within 100 miles of either route. Consequently, anticipated impacts from seismic activity are expected to be the same.

As potential slope instability has been identified along the proposed route and no problems have been identified along this route segment alternative, anticipated impacts are expected to be much greater along the proposed route.

### Mineral Resources

There is insufficient data concerning mineral resources along this route segment alternative to compare impacts to the proposed route.

## Soils

Throughout its length the proposed route between Thompson Pass and the confluence of Prospect and Clear Creeks, lies in deep, well-drained soils described as gravelly, sandy and loamy. Erosion hazard is low because of the gentle slopes and nature of the soil material.

The Driveway Ridge Route passes through well-drained, permeable soils with low to moderate erosion potential, except occasional areas having a highly erodable ash mantle. Slump hazard ranges from low to moderate, with the greatest potential on the slope above Thompson Pass. Here the route parallels a snow avalanche chute. There may be a tendency for a backfill of moderately slumpy soil to move downward along the trench on slopes such as this.

## Aquatic Resources

The five crossings of Prospect Creek on the proposed route would produce silt which would temporarily lower water quality and adversely impact fish spawning beds. The alluvial deposits in the valley bottom are major aquifers. Trenching may change subsurface water flow.

The Driveway Ridge alternative has no creek crossings and crosses no aquifers. Some silt might reach the streams from this route but it would be much less than that resulting from construction along Prospect Creek.

### Terrestrial Vegetation

The proposed route parallels a road and three power lines which require timber-free rights-of-way. If the pipeline can share at least a portion of the cleared right-of-way, the impact on timber production would be considerably less than a route crossing land devoted primarily to timber production. Additionally, the proposed route crosses more than 3 miles of private land used for agriculture or subdivided for homesites. The combination of these factors could result in the long-term removal of more than twice as much land from timber production on the Driveway Ridge alternative.

Vegetation, other than trees, could generally be restored within one year after construction.

### Terrestrial Wildlife

Because the right-of-way would be kept free of tall trees, there is a potential for a long-term increase in forage production as vegetation becomes reestablished after construction. The Driveway Ridge route could have a greater beneficial effect because of its more remote location.

### Cultural Resources

The area crossed by this route segment alternative has not been investigated for the purpose of identifying cultural resource sites.

### Visual Resources

The proposed route follows the highway along Prospect Creek, while the Driveway Ridge alternative is generally out of sight from the road. Conversely, a buried pipeline in the alluvium along the valley floor would not be obvious once vegetation has been reestablished because there are several rights-of-way in the valley bottom and the entire corridor would be kept free of trees. On the other hand, the Driveway Ridge alternative would remain visible as a treeless corridor specifically where it enters the valley.

### Land Use

Because the pipeline right-of-way must be kept free of structures such as houses and barns, the proposed route would have a definite impact on future subdivision and construction along the valley floor. The Driveway Ridge has no forseeable potential for such development, and thus its primary land-use impact would result from the requirement that the corridor be kept free of trees.

### Transportation and Utility Networks

Much of the proposed route is already occupied by a highway, several electric power and telephone lines and a petroleum products pipeline. Relocation of existing facilities might be required and obstruction of traffic during construction could be expected.

No utilities are located on the Driveway Ridge alternative.

### Recreation

The short-term impact of the proposed route is potentially great. The presence of an 8-foot-deep trench, a line of 42-inch pipe being assembled by up to 100 workers operating a variety of large machines would temporarily interrupt most recreational activities in the valley.

Construction clearing, noise, and activity would reduce big game hunting success until suitable browse vegetation and cover had returned (1 to 3 years). The corridor and access roads would attract offroad vehicle use.

This alternate would impact fewer recreationists as compared to the proposed segment.

### Social and Economic Conditions

As mentioned under land Use, the proposed route along Prospect Creek could have a negative impact on land subdivision for residential use because no buildings would be allowed on the right-of-way.

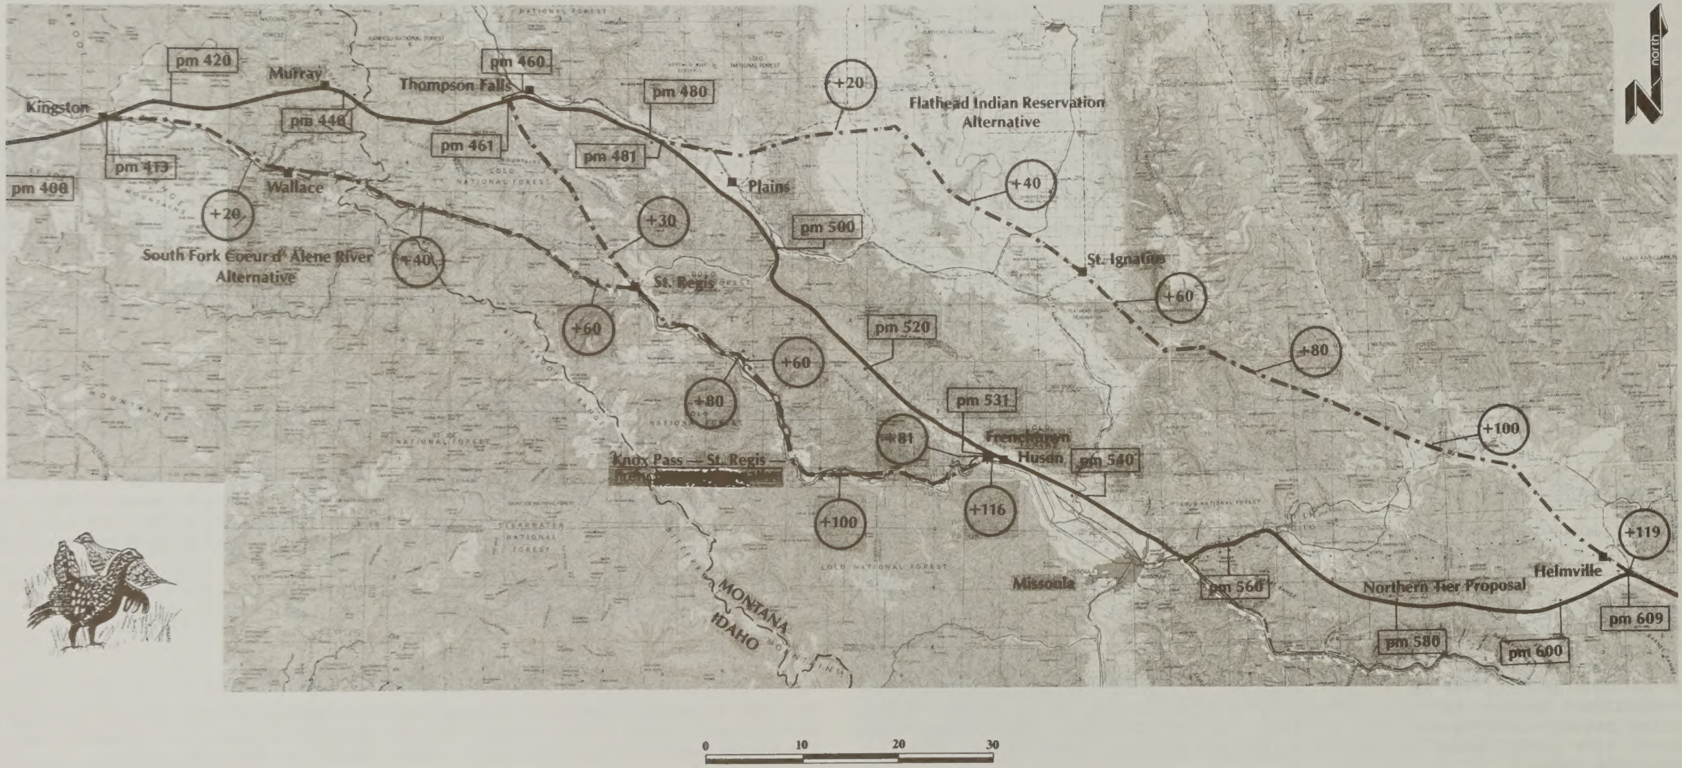
The Driveway Ridge route would have a small economic impact by virtue of the removal of about 6 acres from timber production per mile where the route passes through land currently devoted to timber production. Where the route follows existing trails and roads the loss of timber production attributable to the pipeline would be negligible.

## FLATHEAD INDIAN RESERVATION, MONTANA

The NTPC originally proposed to cross the Flathead Indian Reservation. Refusal by the Flathead Indian Tribal council required the NTPC to change the proposed route to the Siegel Creek-Ninemile Creek area between Plains and Missoula, Montana.

### Description

The Flathead Indian Reservation route begins west of Plains, Montana, in Sanders County at pipeline mile 481 and goes east across the Flathead Indian Reservation to Helmville, Montana (figure 9.4-12). The route crosses state highway 28 and then crosses the western boundary of the Flathead Indian Reservation below Rainbow Lake. Continuing east and then southeast the route crosses state highway 382; parallels



Flathead Indian Reservation • Knox Pass – St. Regis – Missoula •
SouthFork Coeur d'Alene River

Route Segment Alternatives

Figure 9.4-12

Northern Tier Pipeline Company

a powerline, then crosses the Flathead River, the Burlington Northern Railroad and state highway 93 near Saint Ignatius, Montana, the route crosses the east boundary of the Flathead Indian Reservation in Missoula County, continues southeast to a point west of Nevada Lake joining the proposed route at pipeline mile 609. Total distance of this route segment is 119 miles compared to 128 miles for the proposed route.

## Climate

No significant impacts on climte would be anticipated.

## Air Quality

Air quality impacts during construction would be about the same as those for the proposed route. Existing air qualiy levels along this alternate route may be somewhat better than along the proposed route. Fewer residential areas exist along the alternate route so that a smaller population would be potentially affected. Air quality impacts during operation would be negligible.

## Noise

Noise levels during construction would be about the same as those for the proposed route. Fewer residences would be affected than would be the case for the proposed route. No significant noise levels would be associated with the operation phase.

## Topography and Geology

This route segment alternate would cross terrain characterized by moderately rugged mountain foothills and rolling hills flanked by broad alluvial and/or glacial valleys. While somewhat similar to the proposed route in the area (Plains to Helmville--pipeline mile 481 to 609), the average slope is somewhat gentler (12 percent) than the proposed route (18 percent). Consequently, the topographic impacts, consisting primarily of minor landform changes would be less severe (about 8 percent less alteration per mile) than the proposed route.

This route segment alternate would, like the proposed route, cross Precambrian sedimentary/metasedimentary rocks as well as Quaternary glacial and alluvial deposits. Consequently, the impacts to the geologic material would be similar, consisting primarily of the removal and replacement of large volumes of geologic material and some blast and/or excavation-induced changes in the physical characteristics of the geologic material (e.g., cementation, inherent rock strength, porosity, permeability). However, as the average slope along the route segment alternative is about 6 percent less than the proposed route there would be about 40 percent less rock removed during excavation, resulting in a lower impact.

### Geologic Hazards

Geologic hazards that could be encountered along this route segment alternative would be much the same as those that could be encountered by the proposed route in this region and would consist of seismicity and slope instability.

Like the proposed route, this route segment alternative would be located in an area of moderate seismic activity that has been classified by the 1976 Uniform Building Code as a Seismic Risk Zone 2 (moderate earthquake damage expected). Since both routes have experienced similar levels of earthquake activity, the impacts resulting from ground shaking should be approximately the same. Slopes along this route segment alternative are somewhat gentler than along the proposed route so that impacts resulting from liquefaction of bearing sediments, which could occur along the Clarks Fork and Flathead Rivers, should be lower. Four potentially active surface fault ruptures (i.e., faults showing apparent movement within the past 2 to 3 million years) have been identified along this portion of the proposed route, two of which would be crossed (one along Siegel Creek and one east of Missoula). No known potentially active faults have been identified along this route segment alternative. Consequently the anticipated impacts resulting from surface fault movement would be much lower along this route segment alternative.

Although slope instability has been identified along this route segment alternative (route segment pipeline mile +5, +89, +91, +99), the overall slopes are gentler than along the proposed route in this area and should result in lower impacts.

### Mineral Resources

Unlike the proposed route in this area which would interfere with mineral recovery operations along St. Louis Creek (pipeline mile 507) and possibly interfere with gold placer operations along Ninemile Creek (pipeline mile 508 to 515), the route segment alternative would interfere with no known mineral recovery operations. Consequently, the overall impacts on mineral resources would be substantially lower.

## Soils

From Plains the route would extend approximately 35 miles eastward through both alluvial and mountainous soils. From the Flathead River the route would traverse southeastward about 17 miles through soils of Jocko, Moiese, Gird, Tally, Round Butte, Lambeth, Irvine, Post, and Ronsan series. These are well drained, moderately permeable soils occurring on nearly level to sloping topography. The route would continue about 35 miles through soils of Molman, Felan, Winkler, Sharrott, and Holloway series. These are sloping to steep, shallow to deep, loamy forested soils. On crossing the Clearwater River and Blanchard Flat the route would traverse soils of Totelake, Martinsdale, and Holloway series. These are sloping to steep, moderately deep loamy soils. The remaining part of the route to Helmville would parallel Blackfoot River Valley through soils of unknown series. Topography is nearly level for the most part and soils are poorly drained and loamy textured.

Construction activities along the 119-mile route segment alternative would disturb soils on about 1,450 acres as compared to 1,550 acres for the proposed route segment. Potentially significant water erosion impacts would occur along a total of 30 miles in six separate areas. Present soil losses of less than two tons per acre per year with protective vegetation would increase to as much as 15 to 20 tons per acre after vegetation has been removed. This loss rate would continue at a decreasing rate in relation to the increase in vegetation and would return to near normal in 2 or 3 years. Erosion loss comparisons cannot be made between this route segment and the proposed segment due to insufficient base data.

Other soil impacts would be similar to those on the primary route.

Aquatic Resources

### Physical Components

The largest streams crossed along this route segment would be: Clark Fork River, Little Bitterroot River (2 crossings), Flathead River, Jocko River, Placid Creek, and Blackfoot River. All are tributary to the Clark Fork River. Numerous smaller streams would also be crossed. Water quality and discharge data has not been identified for streams along the route. Groundwater resource information has not been identified along this route.

Construction of the pipeline under the streambed would disturb sediments which would temporarly degrade water quality downstream from the crossing in all streams. Erosion from streambanks could contribute sediment to streams during construction and into the operation phase until revegetation occurs. An oil spill would degrade water quality for several miles downstream from the spill site. Impacts on surface water resources along this route segment would likely be less significant since fewer streams would be crossed than along the proposed route.

### Biological Components

Fisheries resources have not been identified in detail along this route segment, however, most streams likely support one or more trout species. In addition, the Clark Fork, and Flathead Rivers support Northern Pike. Nearly all streams probably support forage fish such as minnows and sculpins.

Construction in the streambed and erosion from the streambank would contribute sediments which could damage trout spawning areas and reduce trout populations. Streambank erosion could continue during the operation phase until vegetation becomes reestablished. Since spawning areas have not been identified, it is not known to what extent trout populations would be reduced An oil spill could reduce fish and aquatic insect populations for many miles down stream from the spill site. Recovery of reduced fish population resulting from sedimentation or an oil spill could take several years. Impacts on fisheries resources along this route segment would likely be less significant than those along the proposed route, since fewer streams supporting fisheries resources would be crossed.

Terrestrial Vegetation

The route parallels an existing utility corridor from north of Plains to Rainbow Lake through mostly western ponderosa pine forest. This vegetative community is dependent upon moisture concentrated at outcropings of sandstone or shale layers. Disturbance of these substrates could inhibit or prevent reestablishment of the ponderosa pine community.

At the higher elevations between Plains and Rainbow Lake along the flat dry ridges the following vegetative types are common: subalpine fir/beargrass; subalpine fir/grouse whortleberry; and mountain hemlock/beargrass. Summer forage is low and wildlife winter forage are very low. Timber production and regeneration is low. Reduction of timber stands would probably be permanent.

Plant communities between Rainbow Lake and the Flathead River are principally intermountain valley grasslands and meadows and rangeland characterized by bluebunch wheatgrass and fescue. A major portion of this segment also parallels an existing utility corridor. The proposed route would require additional acreage resulting in an expanded corridor and increased assessibility into the area. Removal of the ground cover and shade plants especially at stream crossings or along the riparian zone of Wilkes Gulch, Little Bitterroot, and Flathead Rivers would cause increased evapotranspiration, erosion, and soil compaction preventing seedling establishment. Grazing or high utilization of the corridor by recreationists and/or wildlife would increase these impacts.

Riparian habitat along the Clearwater, Blackfoot, and Flathead Rivers consists mostly of cottonwood-willow-dogwood types. Douglas-fir is not uncommon in these areas and sometimes dominates the river's edge. Removal of this old growth habitat would impact nesting habitat for raptors and shorebirds and permanently alter the vegetative composition.

The dominant communities between the Flathead River and St. Ignatius are cottonwood-willow-dogwood; bluebunch wheatgrass-fescue; and Douglas-fir. Impacts in this area would disturb riparian habitat and grazing areas associated with Sabine, Mission, and Deep Creek. Reduction of berry bushes and abundant shrub growth would reduce spring forage for bear and deer.

The corridor follows the foothills of Garnet Range and lower elevations of tributaries draining into Nevada Creek. From the Blackfoot River to Helena the dominant vegetation is Douglas-fir-lodgepole pine and Douglas-fir-western ponderosa pine. Reduction of old growth habitat would occur.

Terrestrial Wildlife

The greatest impacts from this route include: 1) increased accessibility to large undisturbed areas, and 2) loss of riparian and winter areas. Habitat for species requiring large spatial distances, i.e. the grizzly bear, would be reduced by increased human disturbance, recreation, and hunting. Wintering ranges used by elk, and deer would be reduced especially along narrow riparian zones, of intermittent and permanent streams. Where the riparian habitat has a disproportionately high use by wildlife, or provides a migration route, long term impacts would result from relatively small alterations and disturbance. The greatest diversity and abundance of wildlife would be impacted along the Flathead River and associated tributaries. Travel corridors and foraging areas used by grizzly bear would be disturbed near Post and Placid Creeks. Disturbance and reduction of old growth habitat could affect bald eagles and other raptors. In comparison most of the impacts resulting from the proposed Ninemile Creek route occur along riparian zones intensively used by wildlife. The diversity and abundance of wildlife in these narrow streamside corridors would be more severely impacted because of habitat reduction. Table 9.4-38 describes short and long term impacts to wildlife. Table 9.4-39 describes anticipated impacts to threatened and endangered species.

TABLE 9.4-38 TERRESTRIAL WILDLIFE ALONG FLATHEAD ALTERNATIVE

| Area/State | Species | Long-Term Impacts | Short-Term Impacts |
|---|---|---|---|
| Rainbow Lake | White-tailed deer, elk and moose<br>Winter habitat north of Rainbow Lake | Increased assessibility to hunting, poaching, recreation and develment pressures | Reduction of limited wintering areas, thermal cover and browse along riparian zone |
| Little Bitterroot River | Important winter habitat for mule deer extends from Wilkes Gulch to Camas Prairie along tributary streams of Little Bitterroot River | Increased assessibility to hunting, poaching, recreation and development pressures | |
| | Pheasant and hungarian partridge habitat along streambottom | Increased assessibility to hunting, poaching, recreation and development pressures | Reduction of lower shrub understory and 1 year's production of young |
| Flathead River | Abundant wildlife habitat along riparian zone for raptors, shorebirds, elk and black bear<br>Islands provide fawning areas for white-tailed deer and nesting grounds for waterfowl and Canadian geese | Removal of fawning and nesting areas and reduction of habitat within the limited riparian zone<br>Removal of old growth habitat for raptors | Disturbance of at least one year's production of waterfowl and big game |
| Montana National Bison Range | Route passes north of the NWR administered by USFWS for bison and other big-game animals | Increased availabliity to human disturbance, harrassment and noise | Disturbance and alteration of forage and browse could result from an oil spill |

TABLE 9.4-38 (Continued)

| Area/State | Species | Long-Term Impacts | Short-Term Impacts |
|---|---|---|---|
| St. Ignatius to South Fork of Jocko River | Migration route bridging important elk winter and summer ranges | Reduction of limited winter range and increased accessibility to hunting, poaching, recreation and development | Vegetation removal would temporarily decrease available browse and thermal cover |
| Placid Lake | Elk calving and winter range | Reduction of limited winter range and increased accessibility to hunting, poaching, recreation and development | Vegetation removal would temporarily decrease available browse and thermal cover |
| Clearwater Lake | Elk and deer winter range | Reduction of limited winter range and increased accessibillity to hunting, poaching, recreation and development | Vegetation removal would temporarily decrease available browse and thermal cover |
| Blackfoot River to Nevada Creek | Elk and deer winter range and calving areas for elk | Reduction of limited winter range and increased accessibility to hunting, poaching, recreation, and development | Vegetation removal would temporarily decrease available browse and thermal cover |

## Cultural Resources

The cultural resource sites listed below would potentially be affected if this route segment alternative is followed. There is high potential for the discovery of additional archaeological and historical sites along this alternative route alignment. The pipeline miles listed in the table have been measured from the place north of Plains, Montana, where this alternative leaves NTPC's proposed route (pipeline mile 481 of the proposed route).

TABLE 9.4-40 CULTURAL RESOURCE SITES, FLATHEAD ALTERNATIVE

There are no currently known paleontological localities along this route segment alternative. The only deposits along the route which have been identified as having potential for containing fossils are fairly extensive Quaternary deposits of glacial drift and lake deposits and alluvium. Fossil materials in these deposits would also have the potential of being associated with prehistoric archaeological material.

Potential impacts to these sites and to any presently unrecorded sites would be the same as those discussed in Chapter 3.

## Visual Resources

The Plains to Helmville alternative route traverses low foothills and rolling hills, and pipeline construction would be relatively simple. This is in sharp contrast to the proposed route that traverses the steep slopes of the scenic Siegel, Ninemile area where installation of the pipeline would cause extensive visual impact.

## Land Use

In Montana the pipeline corridor would cross the Flathead Indian Reservation for a distance of about 60 miles. Land within the reservation includes non-Native American-owned, tribal lands as well as those owned by individual Native Americans. Significant land uses include irrigated and nonirrigated croplands, forest land, and rangeland. The small towns of Moiese and St. Ignatius are within the corridor.

Construction would affect approximately 735 acres within the Flathead Reservation in Montana. Across the Flathead Reservation, construction of pipeline right-of-way and pump stations would impact approximately 235 acres of agricultural, 245 acres of forest, and 255 acres of rangeland.

The pipeline route could impact the Blackfoot River Corridor, a scenic/recreation corridor in western Montana.

## Transportation and Utility Networks

Impacts due to construction, operation, and in the event of an oil spill would be similar to those discussed in the transportation and utility section of chapter 3.

## Recreation

Recreational use and attractiveness of use occurring along this alternate route segment is much greater and more intensive than use occurring along the preferred NTPC route. The major emphasis is for water related activities and hunting. In general, hunting opportunities and potential impacts are similar. However, fishing pressure is greater along this route segment with principal sport fisheries found along the Little Bitterroot, Flathead, Jocko, and Blackfoot Rivers. Placid Lake sustains high fishery and dispersed day recreational use; the proposed pipeline would traverse the southern shoreline.

The area between the Clearwater River and Helmville is heavily utilized as a recreation resource. Numerous campgrounds, and small lakes are found in the vicinity. In addition, the Blackfoot River Corridor between Johnsrud Park and Cottonwood Creek is in the process of being acquired by the Nature Conservancy to be managed for recreation and scenic values. A recently concluded agreement gives the Montana Department of Fish and Game recreational management control for 5 years. Area hunting, river fishing, float boating, and other day and camp uses attracted about 26,000 visits in 1978. An estimated 10 percent increase in use is occurring each year with most of the use between May and September. The proposed corridor would cross The Blackfoot River near Cottonwood Creek, which is 30 miles upstream from Johnsrud Park.

The recently designated Lewis and Clark National Historic Trail also follows the Blackfoot River and is crossed twice by this route segment. The intent of the National Trail System is to preserve the historic or scenic character of the designated trail.

Crossing the Blackfoot River would temporarily disrupt recreational uses and reduce the areas' high scenic value for the life of tne project. A pipeline leak or rupture at the Blackfoot River crossing could contaminate river banks and citically impact conservation easement areas downstream.

## Social Conditions

### Population

The Flathead Reservation occupies portions of four counties: Flathead, Lake, Missoula, and Sanders. Increases in the population during construction and operation phases are not significant. Population increases on Reservation lands would be minimal.

### Infrastructure

No impacts would be expected to occur on the infrastructure components of the Flathead Reservation during the construction and operation phases of this alternative.

### Social Well-Being and Quality of Life

Implementation of this alternative would have significant adverse impacts on the social well-being and quality of life indicators for residents of the Flathead Reservation. The proposed route would cross lands regarded as sacred by members of the tribal groups of the Flathead Nation. To the extent that Native American religious areas are protected by the Indian Religious Freedom bill enacted by Congress in 1978, there is a strong probability that litigation to prevent construction would be initiated by the Tribal Council. The Council already has taken a strong position opposing construction.

# KNOX PASS--ST. REGIS--FRENCHTOWN, MONTANA

The Montana Deptartment of Natural Resources proposed this route segment which leaves the proposed route near Thompson Falls and rejoins it west of Missoula. The purpose was to avoid environmental impacts and public opposition on the proposed route through the Ninemile Valley.

## Description

This route segment begins west of Thompson Falls, crosses Knox Pass on the Lolo National Forest, continues to St. Regis, then follows the Clark Fork to the proposed route west of Frenchtown (figure 9.4-12). Total distance for this route segment is 81 miles compared to 70 miles for the proposed route.

Leaving the proposed pipeline route at pipeline mile 460.5 this route travels south along Dry Creek and Knox Creek to Knox Pass. Continuing, the route follows Twelvemile Creek, the East Fork of Twelvemile Creek and Mullan Gulch to St. Regis. At this point, the route would cross Interstate Highway 90 and the St. Regis River in order to bypass southwest of the town of St. Regis. From here the route would follow the south side of the Clark Fork River, attempting to utilize County road and railroad right-of-way to Huson, Montana. Use of the entire Milwaukee Railroad right-of-way would depend upon abandonment which is presently proposed by the Chicago-Milwaukee-St. Paul-Pacific Railroad Company.

At Huson the route would continue on across the Clark Fork River, joining the proposed route at pipeline mile 531 west of Frenchtown.

Before joining the proposed route and prior to crossing the Clark Fork, this route segment crosses the Milwaukee Railroad which is the beginning of another route segment through Missoula. If the route through the city of Missoula was selected, the Knox Pass--St. Regis route segment to Huson would be about 80 miles, or 1 mile shorter than if it joined the proposed route on the north side of the river.

## Environmental Analysis

### Climate

No significant impacts on climate would be anticipated.

### Air Quality

Emissions of pollutants during construction would be about the same as those for the proposed route (see chapter 3). Air quality impacts would be about the same. No significant impacts would be expected during the operation phase.

### Noise

Noise levels during construction would be about the same as those for the proposed route (see chapter 3). A small number of residences would experience a temporary increase in noise levels. No significant noise levels would occur during the operation phase.

### Topography and Geology

This route segment alternative would cross terrain characterized by moderate to steep mountains (20 to 100 percent side slopes) and a relatively gentle (5 percent gradient), moderately broad (.25 to 2 miles wide) alluvial valley (Clark Fork River). Impacts would be similar to those that would be encountered by the proposed route (Prospect Creek to Frenchtown segment) and would consist primarily of landscape alterations resulting from construction activities. However, as the slopes along this route segment alternative are steeper than the proposed route, the resultant impacts would be somewhat greater (about 14 percent more acreage per mile would be disturbed), particularly along the mountainous northern portion (Prospect Creek to Cabin Creek) of the segment.

Geologic material that would be encountered along this route segment alternative would be essentially the same as that encountered by the proposed route, consisting primarily of Precambrian metasediments (quartzites, argillites, carbonates), Quaternary alluvium and some glacial deposits. Geologic impacts would be similar to those encountered by the proposed route and would consist of minor changes in the physical characteristics of the material resulting from construction activities, and the excavation of large volumes of geologic material. As the average slopes along this route segment alternative are greater, the volume of geologic material that would be removed would also be greater (about 60 percent) than along the proposed route.

#### Geologic Hazards

Seismicity and slope instability are the only geologic hazards that have been identified along this route segment alternative. Like the proposed route in this region, this route segment alternative is located within an area of moderate seismic activity that has been classified by the 1976 Uniform Building Code as a Seismic Risk Zone 2 (moderate earthquake damage expected). It appears that seismic levels along both routes are about the same, consequently impacts from ground shaking are expected to be the same. There is little data regarding the location of potentially active and/or active faults and liquefaction zones along this route segment. Assessment of these potential impacts is not presently possible. In like measure, there is little information pertaining to areas where slope failure could occur; consequently a comparison cannot be made of slope instability impacts to the proposed route.

#### Mineral Resources

While this route segment alternative would cross numerous mining areas, it would not directly interfere with any known mining operations. Consequently, impacts to mineral resources should be less than along the proposed route, which would interfere with a mining operation along St. Louis Creek (pipeline mile 507).

### Soils

The first 7 miles of the route segment alternative traverses stream bottoms, terraces, and low benches. Slopes are nearly level to gentle and soils are deep, gravelly, sandy, and well drained. The route over Knox Pass traverses high, gently rounded divides with slopes up to 35 percent and uniform mountain slopes with gradients of 35 to 65 percent. These mountainous soils are moderately deep to deep cobbly loams developed over argellite and quartzite. Soils of the remaining part of the route are mostly alluvial valley soils that are shallow to moderately deep and are gravelly and cobbly. About 4 miles of this route traverses glacial lakebed deposits with deep, slowly permeable, silty and clayey soils subject to seasonally high water tables.

Approximately 970 acres would be disturbed along this alternate route leaving them vulnerable to accelerated soil erosion. This compares with about 848 acres that would be disturbed along the proposed route. About 19 miles of the alternate route traverses soils on moderately steep to very steep mountainous slopes. Only about 12 miles of the proposed route segment would have similar slopes. Water erosion on these slopes could cause soil losses at rates as much as 70 tons per acre per year until vegetation is reestablished. Other soil impacts would be comparable to those of the proposed route.

### Aquatic Resources

#### Water Quality

Surface water impacts will be higher along this alternate route segment because of the amount of encroachment on streams and the number of creek crossings. Approximately 18 miles of perennial stream would be closely paralleled (immediately adjacent) and sedimentation in the streams would be greatly increased. Potential impacts on the stream channels are high. The greater amount of steep slopes located along this alternate route segment would require more earth moving for leveling a work surface and increase the potential for erosion and sedimention of streams. Ground water impacts along this route segment alternative were not assessed.

Fisheries

Impacts to the fisheries resource would be greater along this route segment alternative than along the proposed corridor. This is due to the greater number of spawning streams crossed and paralleled. Pipeline construction paralleling Dry Creek, Knox Creek and Twelvemile Creek would encroach on these streams, resulting in permanent stream course alteration, channelization, and the introduction of high sediment loads. These creeks are located in narrow, steep-sided mountain valleys with very little flat bottom land. From St. Regis to Frenchtown the route crosses many streams that provide spawning areas for the Clark Fork salmonids.

Terrestrial Wildlife

The Knox Pass -Frenchtown alternate would have slightly less impact on the wildlife resource than the proposed corridor. There would be less thermal cover loss along this alternate as much of the route would parallel existing roads. In the narrow mountain valleys cutbanks required for pipeline construction would create barriers to big game movement. Similar impacts would occur on elk summer range. Impacts to threatened and endangered species might be greater along this alternate because more essential peregrine falcon and bald eagle habitat along the Clark Fork river would be impacted. This impact could be reduced by utilizing as much of the existing road and railroad right-of-way as possible.

Cultural Resources

Given the inadequate inventory data for both the alternate and proposed corridors, it is difficult to assess the potential impacts on cultural resource sites and impossible to compare the potential impacts of the two routings. On the basis of known sites and the indicated site density along the corridors, it appears that appropriate mitigative measures (involving avoidance of sites by minor relocation of the pipeline) would be necessary for some sites in both corridors. Portions of the Mullan Road, located northwest of St. Regis, could be heavily impacted by the alternate location. National Forest management objectives along this old road are to preserve the road and to gradually convert the high density timber stands to the more open stands that existed when the road was built and used in 1860.

Visual Resources

Long-term visual impacts will be greater along this alternate because it traverses more forested land that cannot be revegetated with trees. Approximately 52 miles of the alternate is in close proximity to Interstate 90 but utilization of existing road and railroad rights-of-way would reduce impacts. Approximately 32 miles of the proposed corridor lies in close proximity to State Highway 200, which receives considerably less traffic than I-90.

Land Use

Table 9.4-41 lists the approximate miles of Federal, state and private lands crossed by this alternate, compared to the proposed route.

TABLE 9.4-41 LAND OWNERSHIP, KNOX PASS-FRENCHTOWN ALTERNATIVE

| | Knox Pass-Frenchtown Alternate | Proposed Route |
|---|---|---|
| | Miles Crossed | |
| Federal<br>(National Forest) | 28 | 17 |
| State | 4 | 5 |
| Private | 49 | 48 |
| Total | 81 | 70 |

Impacts to land use would be similar to the proposed route.

Transportation and Utility Networks

Impacts to transportation and utility facilities would be similar to those described in chapter 3. Impacts to the Chicago-Milwaukee-St. Paul Railroad would be lessened if the right-of-way is abandoned as proposed by the railroad company.

Recreation

Both the alternate route segment and proposed route have similar recreational characteristics. Impacted activities would be hunting, fishing, and driving for pleasure. This alternate would have less overall impact on recreationists due to the smaller amount of backcountry area traversed and generally wider Clark Fork River valley along this segment. If the Milwaukee Railroad right-of-way is utilized, significantly less impact to recreational uses would occur.

## SOUTH FORK COEUR D'ALENE RIVER, IDAHO--MISSOULA, MONTANA

The NTPC evaluated a possible route along the South Fork Coeur d'Alene River as an alternate to the originally proposed route along the Coeur d'Alene River. The company concluded that a route along the South Fork was not feasible (primarily due to limited available right-of-way and the high cost of construction). More specifically, the company determined that numerous mining claims, limited space in Wallace and Mullan, Idaho, and highway interruption would cause both difficult and expensive pipeline construction, therefore the company developed a proposed route from Kingston, across Jackson Ridge to Thompson Falls.

Idaho, envrionmental groups, and private citizens have requested BLM to consider an alternate route along the South Fork Coeur d'Alene River. BLM has proposed a route segment from Kingston, Idaho, paralleling the South Fork Coeur d'Alene River to Montana, along the St. Regis River to St. Regis, and then along the Clark Fork River rejoining the proposed route west of Missoula.

A more complete route segment description along with an environmental analysis comparing this alternate route segment with the proposed route follows. The analysis for this alternate is based on limited information.

### Description

This alternate would begin at pipeline mile 413 near Kingston, Idaho, follow the south side of the South Fork Coeur d'Alene River through Wallace and Mullan, Idaho (figure 9.4-12). Starting at Mullan, the potential exists for using the Burlington Northern Railroad right-of-way due to future plans for abandonment. If railroad right-of-way was available for pipeline construction, it could be used to Haugan, a distance of approximately 30 miles. From Haugan to St. Regis, the route would continue on available railroad right-of-way or be routed north from near De Boria along a county road to St. Regis. East of St. Regis, the route could follow along the south side of the Clark Fork River, crossing the river near Huson and rejoining the proposed route at pipeline mile 531, west of Frenchtown. Total distance for the route segment would be approximately 116 miles compared to 118 miles for the proposed route from Kingston to Thompson Falls, along the Clark Fork River, through the Ninemile Valley to Frenchtown, west of Missoula.

The environmental anlysis of this route segment will be summarized due to limited information available for comparison to the proposed route. Major environmental advantages would be the avoidance of impacts across National Forest lands, aquatic impacts along Prospect Creek, public opposition through Ninemile Valley and impacts to the Clark Fork River. Major disadvantages would be engineering feasibility, limited right-of-way in Wallace and Mullan, unknown public opposition and the potentially higher cost of pipeline construction. If the NTPC project were approved for construction, the final selection of the preferred pipeline route between Kingston, Idaho and Missoula, Montana warrants a complete engineering feasibility and economic study. This study should include use of the Milwaukee Railroad and a portion of the Burlington Northern Railroad rights-of-way which may be abandoned and available for the pipeline route. Therefore the feasibility of the South Fork Coeur d'Alene route segment is presented for consideration but it can only be adequately evaluated in the future, prior to NTPC construction and resolution of the railroad abandonment proposals.

## NINEMILE VALLEY, MONTANA

This alternative was proposed to reduce the mileage of the proposed route across private lands in the Ninemile Valley area between Siegel Pass and Missoula (U.S. Forest Service, Comment Letter March 1979). The following description and environmental analysis were adapted from the Environmental Assessment on the Ninemile-Frenchtown alternative prepared by the U.S. Forest Service (May 1979).

The alternate route segment for Ninemile Valley begins at Siegel Pass leaving the proposed route at pipeline mile 506, traverses Lolo National Forest land above Ninemile Creek, then rejoins the proposed route at pipeline mile 539 east of Frenchtown (figure 9.4-13). This route crosses 24.8 miles of federal and state land, and 7.4 miles of private land compared to 11.1 miles and 21.6 miles, respectively, for the proposed route. Total distance would be similar, about 32 miles for the alternate and 33 miles for the proposed route.

### Environmental Analysis

#### Climate

No significant impacts on climate would be anticipated.

#### Air Quality

Air quality impacts during construction would be about the same as those associated with the proposed route (see chapter 3). No significant impacts would be expected during the operation phase.

#### Noise

Noise levels during construction would be about the same as those for the proposed route (see chapter 3). A small number of residences would experience a temporary increase in noise levels. No significant impacts would occur during the operation phase.

#### Topography and Geology

Like the proposed route, this route segment alternative would result in relatively minor topographic impacts, primarily landscape changes and some drainage alteration. The most pronounced impacts would be along the western portion of the route, near Seigel Pass, where the route would traverse moderately steep terrain and would disturb about 18 to 20 acres per mile.

While this route segment alternative is somewhat steeper than the proposed route, the amount of land disturbed per mile is nearly identical; consequently, the topographic impacts would be essentially the same.

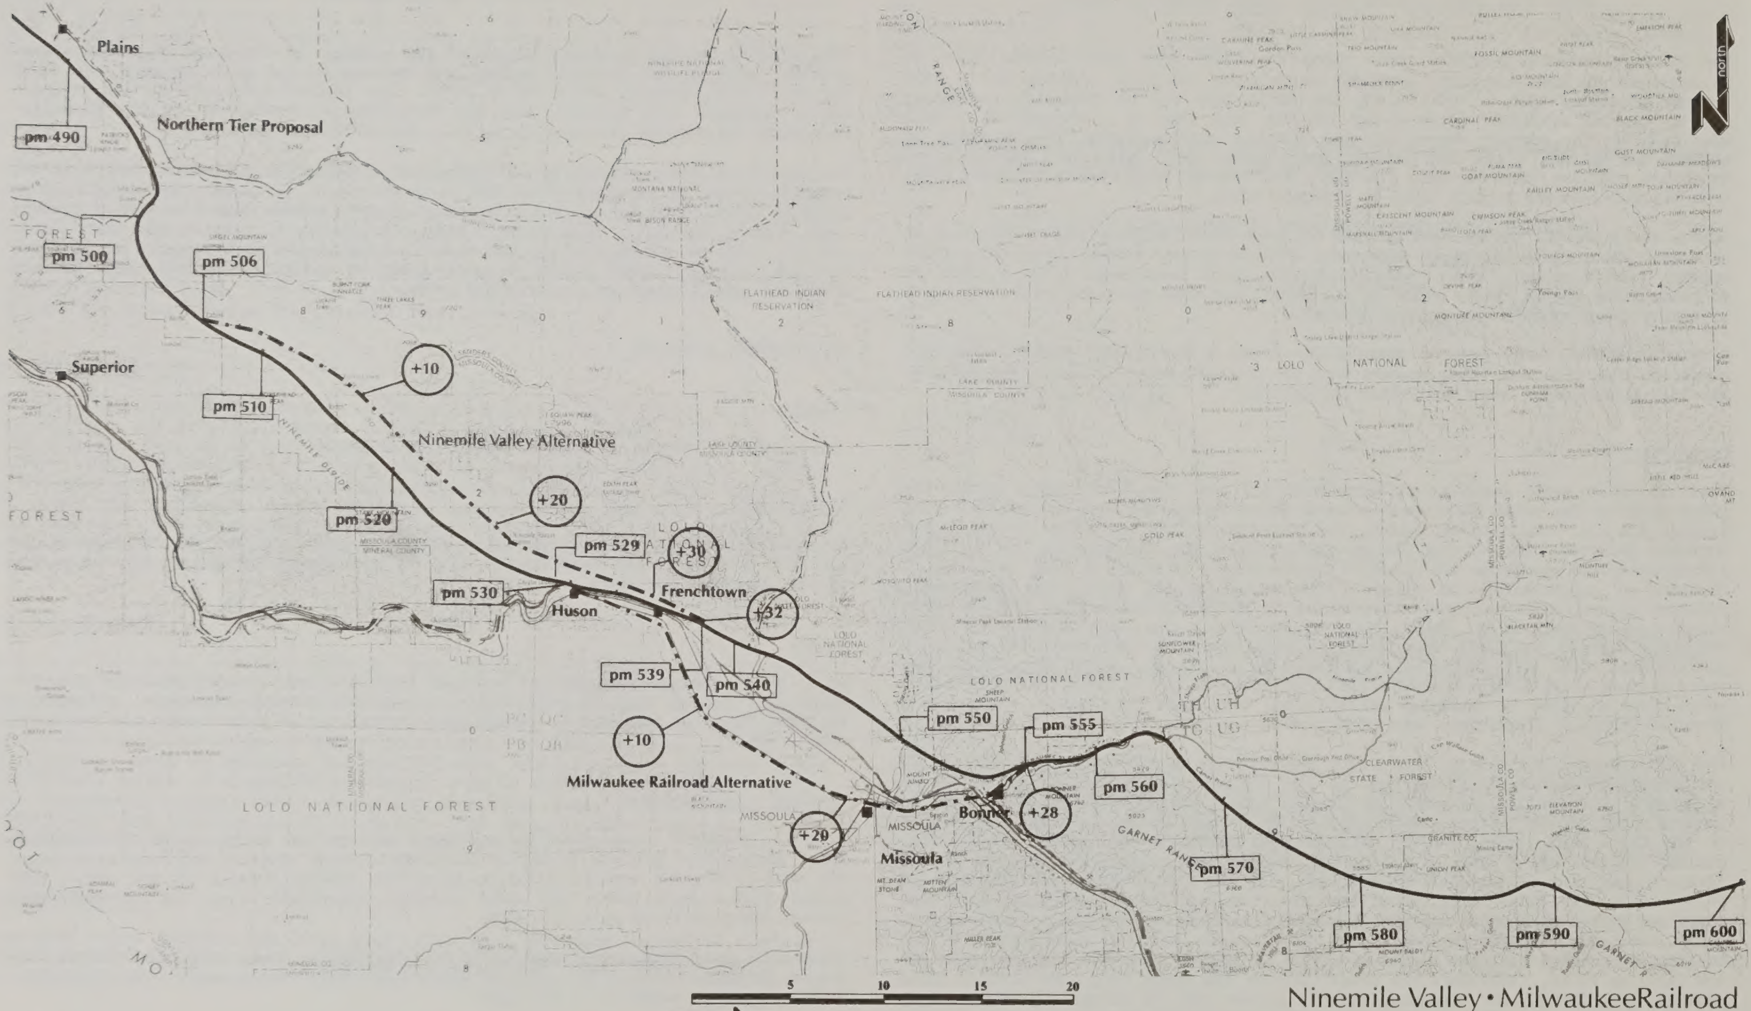

Figure 9.4-13

Northern Tier Pipeline Company

Ninemile Valley • MilwaukeeRailroad
Route Segment Alternatives

Geologic material encountered by this route segment alternative would be much the same as that encountered by the proposed route, consisting primarily of loosely consolidated Tertiary sediments and Quaternary glacial deposits. Resulting geologic impacts would be similar. They would include production of waste material unsuitable for fill and changes to rock characteristics. Since this alternative route crosses steeper terrain than the proposed route, about 26 percent more rock material would be excavated (U.S. Forest Service 1979).

### Geologic Hazards

This route alternative, like the proposed route in this area, would be within a region of moderate seismic activity classified by the 1976 Uniform Building Code as a Seismic Risk Zone 2 (moderate earthquake damage expected); it would also parallel the potentially active Ninemile fault from Siegel Pass (pipeline mile 506) to just west of O'Keefe Creek (segment pipeline mile 31.5). Consequently, seismic-related geologic hazards that could impact the proposed route would be the same. While surface movement along Ninemile fault is considered unlikely during the lifetime of the project, ground shaking could result in significant or critical impacts to the pipeline through slope failure or liquefaction of the loose sediments. Since the route alternative is situated much closer to the unstable brecciated zone along the Ninemile fault and crosses steeper terrain, seismic impacts would be significantly greater than the proposed route.

In addition to seismic related geologic hazards, slope instability problems have been identified along the entire route alternative. While both the proposed route and the alternate route would cross loose or loosely consolidated material, the route alternate would cross steeper terrain. Consequently, the impacts would be greater.

### Mineral Resources

Both the proposed route and alternate route would cross copper-silver mining claims along St. Louis Creek and several placer claims along Ninemile Creek. Consequently, impacts on mineral development would be the same.

## Soils

For the proposed route total soils impact would be about 356 acres. The alternate route would cause about 351 acres of disturbed soils.

Although the acreage of soil disturbance is similar, the impact upon soils would be greater on the alternate route where moderately sloping ground and erosive soils exist. Also, these soils are not conducive to rapid revegetation following pipeline construction.

## Aquatic Resources

### Water Quality

Water quality impacts would be greater on the alternate route than on the proposed route through Ninemile Valley. During the construction phase, greater stream sedimentation would occur, primarily due to the steeper slopes. The alternate route would have 57 crossings of intermittent and perennial streams compared to 47 for the proposed route. Combining the effects of sedimentation and the number of stream crossings, the water quality impacts would be about 1.4 to 2.0 times greater on the alternate route than on the proposed route (U.S. Forest Service May 1979).

During pipeline operation water quality impacts from potential leaks or pipe failure would be similar for both the alternative and the proposed route through Ninemile Valley. Crude oil effects upon water quality could occur for Ninemile Creek, Sixmile Creek, and possibly the Clark Fork River since both routes traverse the entire watershed.

Ground water resources are common to both the alternative and proposed routes; potential crude oil impacts are estimated to be similar.

### Fisheries

Pipeline construction and operation impacts would be greater on the proposed route rather than on the alternative. Although there would be 10 more stream crossings on the alternative route, the fishery potential is greater on the proposed route. Ninemile Creek is an important spawning and rearing stream for salmonids which provide recruitment to the Clark Fork River fishery. This higher fishery value for Ninemile Creek results in greater potential oil spill or sedimentation impacts.

Water quality impacts from sedimentation would have a proportionally greater impact on the fisheries along Ninemile Creek. This would mainly result from the lower stream gradients where sedimentation would have a greater effect. Sediments from stream crossing construction would be deposited in Ninemile Creek at a higher rate than those in streams on the alternative route along the steeper gradient. The lower stream gradients along Ninemile Creek would also have greater sedimentation impacts from lack of potential flushing.

## Terrestrial Vegetation

The proposed and alternative corridors located in the Ninemile Creek drainage traverse similar habitat groups. These groups are composed of habitat types segregated according to the physical environments they represent as determined by soil, slope, aspect, elevation, physiographic site, and climate. These factors interact to affect growing season temperatures, available moisture, and length of growing season. Group 0 (Noncommercial) is not included in the timber production base and therefore would have low impact on timber production from pipeline activities.

Group 1 (warm and dry) is characterized by open-crown ponderosa pine or Douglas-fir. Productivity is low, averaging about 3 cubic feet per acre per year with intensive management. Impacts from pipeline activities would also be low in this group.

Group 2 (moderately warm and dry) and Group 3 (moderately cool and dry) are generally dominated by Douglas-fir, with varying amounts of ponderosa pine, lodgepole pine and grand fir. Timber productivity is moderate to moderately high, averaging 70 cubic feet per acre per year under intensive management. Group 5 (cool and moderately dry) is characterized by essentially pure stands of lodgepole pine. Timber production is variable, averaging 55 cubic feet per acre per year under intensive timber management. Pipeline activities would have a medium impact on the timber productivity potential in these three groups.

Group 4 (moist) represents areas where temperature and moisture approach optimum conditions for vegetative growth within the forest community. Stand composition varies from pure spruce to mixtures of Douglas-fir, larch, grand fir, subalpine fir, hemlock and cedar. Lodgepole is found throughout the group. Potential yields average 110 to 115 cubic feet per acre per year. Removal of acreage from timber production in this group would have a high impact on the productivity potential.

Table 9.4-42 summarizes the miles of each habitat group crossed, the acres impacted, and the volume of timber that would be removed for the proposed corridor and its alternative in the Ninemile Creek drainage.

TABLE 9.4-42 HABITAT GROUPS CROSSED, NINEMILE VALLEY ALTERNATIVE

| | | Habitat Group | | | | | |
|---|---|---|---|---|---|---|---|
| | | 0 | 1 | 2, 3, 5 | 4 | Total | Total Timber Removal Volume-MBF |
| Impact Rating | | Low | Low | Mod | High | | |
| | Miles Crossed | 13.6 | 2.8 | 12.0 | 4.3 | 32.7 | |
| Proposed | | | | | | | 1593 |
| | Acres | 150 | 31 | 132 | 47 | 360 | |
| | Miles Crossed | 1.9 | 3.2 | 21.8 | 5.3 | 32.2 | |
| Alternative | | | | | | | 2641 |
| | Acres | 21 | 35 | 240 | 58 | 354 | |

The proposed corridor has a lower impact on forested land because fewer miles are located on the better timber-growing sites.

Terrestrial Wildlife

The wildlife resource assessment is based on the expected impacts resulting from changes in the winter and summer habitats and the critical winter thermal cover of big game animals. The effects on several bird species intolerant of habitat disturbance and for some birds more tolerant of disturbance is also included. Impacts to threatened and endangered species are considered separately from the above analysis.

Impact potentials are rated high on thermal cover and essential threatened and endangered wildlife habitat because of the probability that pipeline activities would prevent use of these areas by wildlife over a long period of time. The summer and winter habitats are rated as having a low impact potential because of the relatively short duration of impact during construction, the availability of other suitable habitat in close proximity, and the probability that the construction zone would provide browse within one or two year years after construction. Summer and winter habitats that may suffer longer-term impacts are noted. Impacts to birds are dependent on the amount of habitat modification that the species can tolerate.

Along the proposed route summer range for low numbers of deer and elk is provided in the upper area near Siegel Pass. Escape cover is currently limited. Pipeline clearing would further reduce this cover, but this would be short-term as the existing clearcuts would provide additional cover in 3 to 5 years. As a result of linking existing clearcuts to the pipeline clearing, edge-associated wild life species such as the western flycatcher, ruffed grouse, yellow-rumped warbler, junco, western tanager, chipping sparrow, saw-whet owl, and sparrow hawk would be adversely affected. Old-growth habitat would also be reduced along this segment. This would slightly impact old-growth dependent species such as the goshawk, Coopers hawk, Swainson's thrush, hermit thrush, Clark's nutcracker, Hammond's flycatcher, Townsend's warbler, pygmy owl, and great gray owl.

As the route segment descends to the valley bottom, winter range is encountered. This area also provides habitat for open country birds such as the kingbird, golden eagle and rough-legged hawk. This lower portion of the route passes through subdivisions, rangeland and small irrigated pastures. In general, impacts to the wildlife resource have already been made, and a pipeline would create little additional impact.

The proposed corridor segment would have a low to moderate impact on the existing summer range from Siegel Creek to Little Blue Creek. Impacts on winter range and the chance of increased harassment to big game would be minor because the existing influence of subdivisions and residences, road use, and noise are more overriding.

Impacts along the alternate corridor in the Siegel Pass area would be similar to those for the proposed route. The summer range presently has good forage values and a corridor opening would not improve browse conditions for big game. The remainder of this alternate route would cross transitional spring and fall range or winter range.

Big game use is moderately high from Blue Creek through Spring Creek (western mid-portion of segment). The Josephine Creek drainage is heavily timbered with second growth. Clearing impacts in this drainage should not be severe because of the high proportion of cover. Deer and elk use is high in McCormick Creek. Slopes between the forks in the drainage are 50 to 60 percent. Cutbanks resulting from pipeline construction would create a barrier for deer and elk, which would significantly inhibit them from using the area.

Butler Creek is bordered by private land which has been cleared or thinned. Big game use is slight to moderate and corridor clearing would have minimal impact.

The Spring Creek drainage contains critical winter range. Pellet data taken in April 1979 indicates 30-50 elk and 50-80 deer were concentrated in this area during the winter. The timber has recently been thinned and the present cover/forage ratio is 30/70. This is below an optimum of 50/50. Any further reduction of cover would significantly lower the present carrying capacity. The thermal cover zone is now less than 200 acres in total. Minumum thermal cover limits for elk have been established at 70 acres. Right-of-way clearing would sever this zone and leave two isolated islands that would not provide adequate winter thermal cover for elk. Deer do not require as large a thermal cover zone and would not be as negatively affected. Winter forage is not a limiting factor in this drainage so increased forage production in the right-of-way would be of little benefit to big game.

Towards the eastern end of this segment valuable deer and elk winter range occurs, particularly in the Roman and Edith Creek areas. During the winter of 1978-79, approximately 25-30 elk and 100 deer used this area. The population appears to be very close to the present winter range carrying capacity. The cover/forage ratio is near optimum at 50/50.

The effects of right-of-way clearing would be extremely adverse. The winter thermal cover provides an essential habitat requirement due to heavy snowfall and prolonged cold periods in the area; clearing would remove a portion of this critical cover. The clearing would also accumulate deeper snowpacks due to the loss of interception by trees and this would result in a barrier to animal movement. These conditions would put extreme stress on the animals and result in decreased survival rates.

This eastern end of the segment is currently subject to an increasing amount of off-road-vehicle use, particularly with snowmobiles. This is causing increased stress upon wintering deer and elk. Clearing of a right-of-way would aggravate the problem by creating a tree-free track.

The edge-associated wildlife species found along this segment would have similar impacts as those associated with the proposed corridor segment, and would be minor.

The western half of this alternative segment contains some excellent old-growth habitat for birds. An active Cooper's hawk nest near Big Blue Creek could be lost during right-of-way clearing. Other old-growth dependent species would be impacted to a degree similar to that along the proposed corridor. Snag-using wildlife would be severely impacted. Pileated woodpeckers which now nest along this alternate corridor might suffer a 10 percent reduction in habitat availability. The eastern one-third of this corridor contains only marginal habitat for several oldgrowth dependent species, and the impacts would be minimal.

In summary, this alternative would cause higher impacts on the wildlife resource than the proposed route. This alternative would cross more high-quality winter range, and increased snow accumulation in the cleared right-of-way would create barriers. Critical winter thermal cover would be eliminated, resulting in reduced big game populations.

Three threatened and endangered species are found in the vicinity of Ninemile Valley: the bald eagle (endangered), the peregrine falcon (endangered), and the grizzly bear (threatened).

Ranch and forest land, Ninemile Valley

Essential bald eagle winter habitat parallels the lower (east) end of the proposed route and the alternative. Neither route would cause any impact on bald eagles.

There is some essential peregrine falcon habitat near the mouth of Ninemile Creek, but this would not be impacted by pipeline construction or operation.

No portions of the proposed or alternate pipeline corridor is within identified grizzly habitat. Neither corridor would create additional impact upon the grizzly bear.

### Cultural Resources

The area which would be crossed by this route segment alternative has not been investigated for the purpose of identifying cultural resource sites.

### Visual Resources

Generally, the upper half of the proposed route has higher visual impacts than the upper half of the alternate route, and the converse is true of the lower portions of the two routes. As a result, neither route is clearly superior to the other from the standpoint of visual resources. It appears that by connecting the upper portion of the alternative route with the lower portion of the proposed route an overall route of minimum visual impact might be achieved.

### Land Use

Nearly 22 miles of the proposed route are located on private land, while only 7 miles of the alternate route crosses private land. The remainder in each case is on National Forest land. The pipeline could have a significant impact on private land in an area such as this where subdivision for homesites is occurring, because no buildings would be permitted on the right-of-way. The proposed route would cause a correspondingly greater interference with agriculture during the construction year than would the alternate.

Impacts to transportation and utility networks for the alternate route would be similar to the proposed route as described in chapter 3.

### Recreation

The Ninemile Creek drainage offers a wide variety of opportunities for year-round recreation, but because there are no outstanding attractions the present use is primarily by local people and is well below the capacity of the area. However, recreation use is increasing rapidly and is expected to continue to do so as long as subdivision of private land in Ninemile Valley and population growth in the surrounding areas continues.

The foothills and lower slopes are used for horseback riding, hiking, wildlife viewing, hunting, fishing, snowmobiling, snowshoeing, nordic skiing, and snow play.

The proposed route runs within one- to three-quarters of a mile upslope of three concentrated-use areas: Burnt Fork Creek, Soldier Creek, and Camp Creek, and passes almost directly over the Little Blue Lookout site which, although no longer in service as a fire lookout, serves as a recreational viewing point. In the short term, use of these sites would be curtailed or discontinued because of the disturbances associated with construction.

The alternative is a mile or more from these sites and would have considerably less impact during construction; however, it does pass within one-half mile of the old CCC camp site and a quarter-mile of the old Frenchtown Ranger Station site. After construction has been completed the impacts on these concentrated-use sites would diminish rapidly and the pipeline right-of-way could begin to serve as a recreation corridor. This could occur during the first year for sports such as snowmobiling, nordic skiing and motorcycling. As the soil becomes stabilized and vegetation reestablished (3-5 years) hiking and horseback riding along the right-of-way may become attractive to some local residents.

Both the proposed route and the alternate would have short term adverse impacts on fishing because of the disturbance associated with construction. Reduced hunter success would also occur as a result of construction activities and continue for 1 to 3 years, or until suitable browse and cover vegetation is stabilized. The alternate route could have less impact than the proposed route which crosses the lower reaches of streams triburary to Ninemile Creek.

The overall effects on recreation are similar for both the proposed route and the alternate. Neither stands out as being significantly better than the other. Barring a major oil spill, recreation activity would not be seriously impacted by either route in the long term.

### Social and Economic Conditions

#### Population

During the peak period of the construction phase 493 nonlocal workers would be added to the Missoula County population. The total population increase, of approximately 1,100 persons, is not considered to be significant. Population increases occurring as the result of the operation phase would be minor in proportion to the existing population projections and are not considered significant.

#### Infrastructure

Strains on infrastructure components would occur. Due to the relatively short duration of the peak construction period these would not be significant. No significant negative effects would occur on infrastructure components during the operation phase.

#### Social Well-Being and Quality of Life

Approximately 2,000 people live in the vicinity of the Siegel Pass-Ninemile pipeline segment in the towns of Huson and Frenchtown, and in settlements and on ranches in the Mill Creek, Sixmile, and Ninemile Valleys.

In February, 1979, the Northern Tier Pipeline Company announced that the proposed primary pipeline route would be located in the Siegel Pass and Ninemile Valley area instead of the Flathead Indian Reservation.

A portion of the property owners in Frenchtown and the Valley settlements formed the Valley Preservation Council as a means of developing and focusing residential interest on proposed pipeline construction and operation concerns. Strong opposition to the proposed project has been expressed by many of the local residents at public meetings and in letters.

The project would have no significant impacts on such social well-being indicators as employment opportunities, personal income, or governmental services. However, quality of life indicators would be negatively affected by the construction and operation phases. For example, recreational opportunities would be diminished during the construction phase. Residents perceptions of the aesthetic setting of the region would be changed by alterations in the existing scenic status of forested lands due to construction and operation of the pipeline. Concerns over the quality of water would be increased by fears of potential oil spills and/or accidents. The valley area, as a "place to live" would be changed from its present, relatively natural, atmosphere.

### MILWAUKEE RAILROAD, MISSOULA, MONTANA

On February 6, 1979 the Missoula Planning Board requested that NTPC examine the feasibility of using the existing Milwaukee Railroad right-of-way rather than using the proposed route on the north side of Missoulá. This was recommended because the Milwaukee Railroad has announced plans to abandon all facilities in western Montana. The Missoula Planning Board's purpose was to avoid the proposed route crossing Rattlesnake Creek, an area of public significance, and to use the completed pipeline right-of-way through Missoula as a parkway that could have significant recreational and aesthetic value.

On March 26, 1979, NTPC requested BLM to evaluate an alternate route through the city of Missoula utilizing the Milwaukee Railroad right-of-way. NTPC provided a description and feasibility study which has been used for BLM's evauation (April 1979). The alternate route would use the Milwaukee Railroad right-of-way from Huson through Missoula to Bonner where it rejoins the proposed route.

This alternate route would depart from the proposed route at pipeline mile 529, west of Frenchtown, and join the railroad right-of-way near Huson (figure 9.4-13). The route continues on right-of-way through the city of Missoula, across the Clark Fork River, and rejoins the proposed route near Bonner at pipeline mile 555.

It would use 25 miles of the railroad right-of-way. Total distance for the alternate would be about 28 miles compared to 26 miles for the proposed route. Additional crossings would be two on the Clark Fork River, two on Interstate Highway 90, eleven on asphalt roads, and five on railroads. NTPC would be required to use special construction conditions for about 24 miles, due primarily to traffic congestion.

The alternate route using the railroad right-of-way has fewer construction impacts upon private land use but there is more potential for contamination of aquatic resources during operation. The publicly significant Rattlesnake Creek area on the proposed route is avoided but the additional crossings and closer proximity to the Clark Fork River and the Missoula city water supply causes potential impacts on the alternate route.

The alternate route avoids soils and geologic impacts attributed to the proposed route along the north side of Missoula. Soil erosion and slope instability problems exist for the proposed route but would be avoided for 25 miles of the 28-mile alternate.

Seismic hazard potential along the Missoula Valley would be similar for both routes. As the alternate route would be further from the trace of the Ninemile Creek fault zone than the proposed route, anticipated impacts (ground shaking, surface fault rupture, liquefaction) resulting from movement along this fault would be less. However, the alternate route would cross a fault east of Missoula that the proposed route would avoid. Consequently, the anticipated impacts resulting from movement along this fault would be greater along the alternate route. As both faults have shown apparent movement within the past 2 to 3 million years, they are both considered potentially active. A small magnitude earthquake may have occurred along one of them within the past few years, suggesting that the potential for movement along both faults needs further study prior to the estabishment of final design criteria.

Potential contamination from pipeline leaks or rupture exists for the Missoula city water supply. The alternate route bypasses six wells that make up the majority of the city water supply. These groundwater wells vary between 100 to 150 feet deep and are recharged by the Clark Fork River. Due to their close proximity to the railroad right-of-way, a pipeline leak into either the Clark Fork River above the wells, or into the groundwater supplies would contaminate the Missoula city water supply. This potential impact would be greater on the alternate rather than the proposed route, which crosses below the intake for water supply from Rattlesnake Creek.

Land use impacts upon private lands would be reduced on the alternate route. For the total distance of 28 miles only 3 miles would be across private land, the remaining 25 miles located on railroad land.

Impacts on transportation during construction could be greater on the alternate route. This route would cross Interstate 90 twice and 11 other asphalt roads. Missoula bypass traffic on Interstate 90, and local traffic would probably have more interruptions on the alternate route. During the operation phase, there would be negligible impacts upon transportation and utilities for either the proposed or the alternate route.

Social impacts of the alternate route would consist mainly of short-term traffic congestion and public interference during the construction period. This would probably continue for a slightly longer period of time due to special construction techniques required through the city of Missoula. Social impacts upon population, housing or public facilities would be similar for the alternate and proposed route since employment for this construction spread would probably occur in Missoula.

Economic benefits would result from increased construction costs for the alternate route. NTPC estimates a \$15.4 million cost for the proposed segment compared to \$25 million for the alternate segment. The \$9 million increased cost would benefit employment and stimulate the local economy of Missoula during the construction period. Social and economic impacts during the operational phase would be similar for both route segments.

## MISSOULA-GARRISON-HELENA

NTPC originally proposed the Missoula-Garrison-Helena alternative to eliminate crossing the Flathead Indian Reservation and as an alternative to the proposed route.

This route would start from Missoula, Montana, follow Interstate 90 to Garrison, and State Highway 12 to Helena for a total distance of 115 miles (figure 9.4-14).

Beginning east of Missoula at pipeline mile 555, in Missoula County, the route would travel south along the south side of the Clark Fork River. East of Missoula the route would follow the Burlington Northern Railroad and Interstate 90 to Garrison, then State Highway 12 to Helena, joining the proposed route at pipeline mile 656. Total distance would be 115 miles as compared to 101 miles for the proposed route.

### Climate and Air Quality

No impacts on climate are anticipated for this alternative pipeline route.

Air quality impacts would be similar to those for the other alternative route segments.

### Noise

Noise impacts associated with pipeline construction and operation would be similar to those associated with the other alternative route segments. Some scattered residences would be affected by construction noise.

### Topography and Geology

This route segment alternative would cross moderately steep mountains and small intermontane Tertiary basins, intersect numerous small drainages, the Clark Fork and Little Black Rivers. Topography is similar to that of the proposed route. Topographic impacts consisting of landscape changes and some temporary drainages alterations, would be essentially the same. Both routes would encounter similar geologic material consisting of Precambrian sedimentary/metasedimentary rocks, Mesozoic/Paleozoic marine sediments, Tertiary/Cretaceous granitic rocks, Tertiary nonmarine sediments and volcanic rocks, and Quaternary alluvium. Impacts to geologic material including excavation of large volumes of material and some change in the physical characteristics of the geologic material (e.g., porosity, permeability, inherent rock strength, moisture content), would be nearly identical to the proposed route.

### Geologic Hazards

As with the proposed route, this route segment alternative would cross a region exhibiting two levels of seismicity--an area of moderate activity corresponding to a Seismic Risk Zone 2 (moderate earthquake damage expected) between Missoula (Garrison alternate route pipeline mile 0) and McDonald Pass (pipeline mile 85), and an area of high seismic activity corresponding to a Seismic Risk Zone 3 (maximum earthquake damage expected). Both the proposed and alternative routes would cross the active Prickly Pear Fault (pipeline mile 655) and come within 2 miles of the active Scratchgravel Hills Fault (2 miles north of the Prickly Pear Fault). However, the proposed route would cross an additional fault (potentially active) near Snowshoe Creek

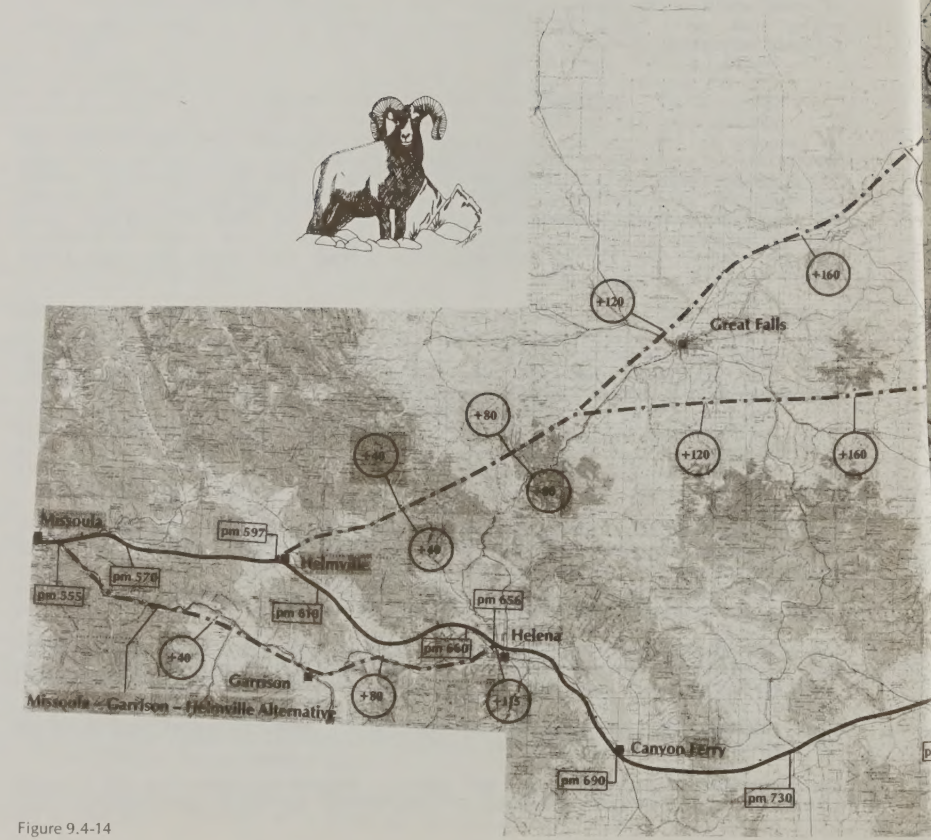

Figure 9.4-14

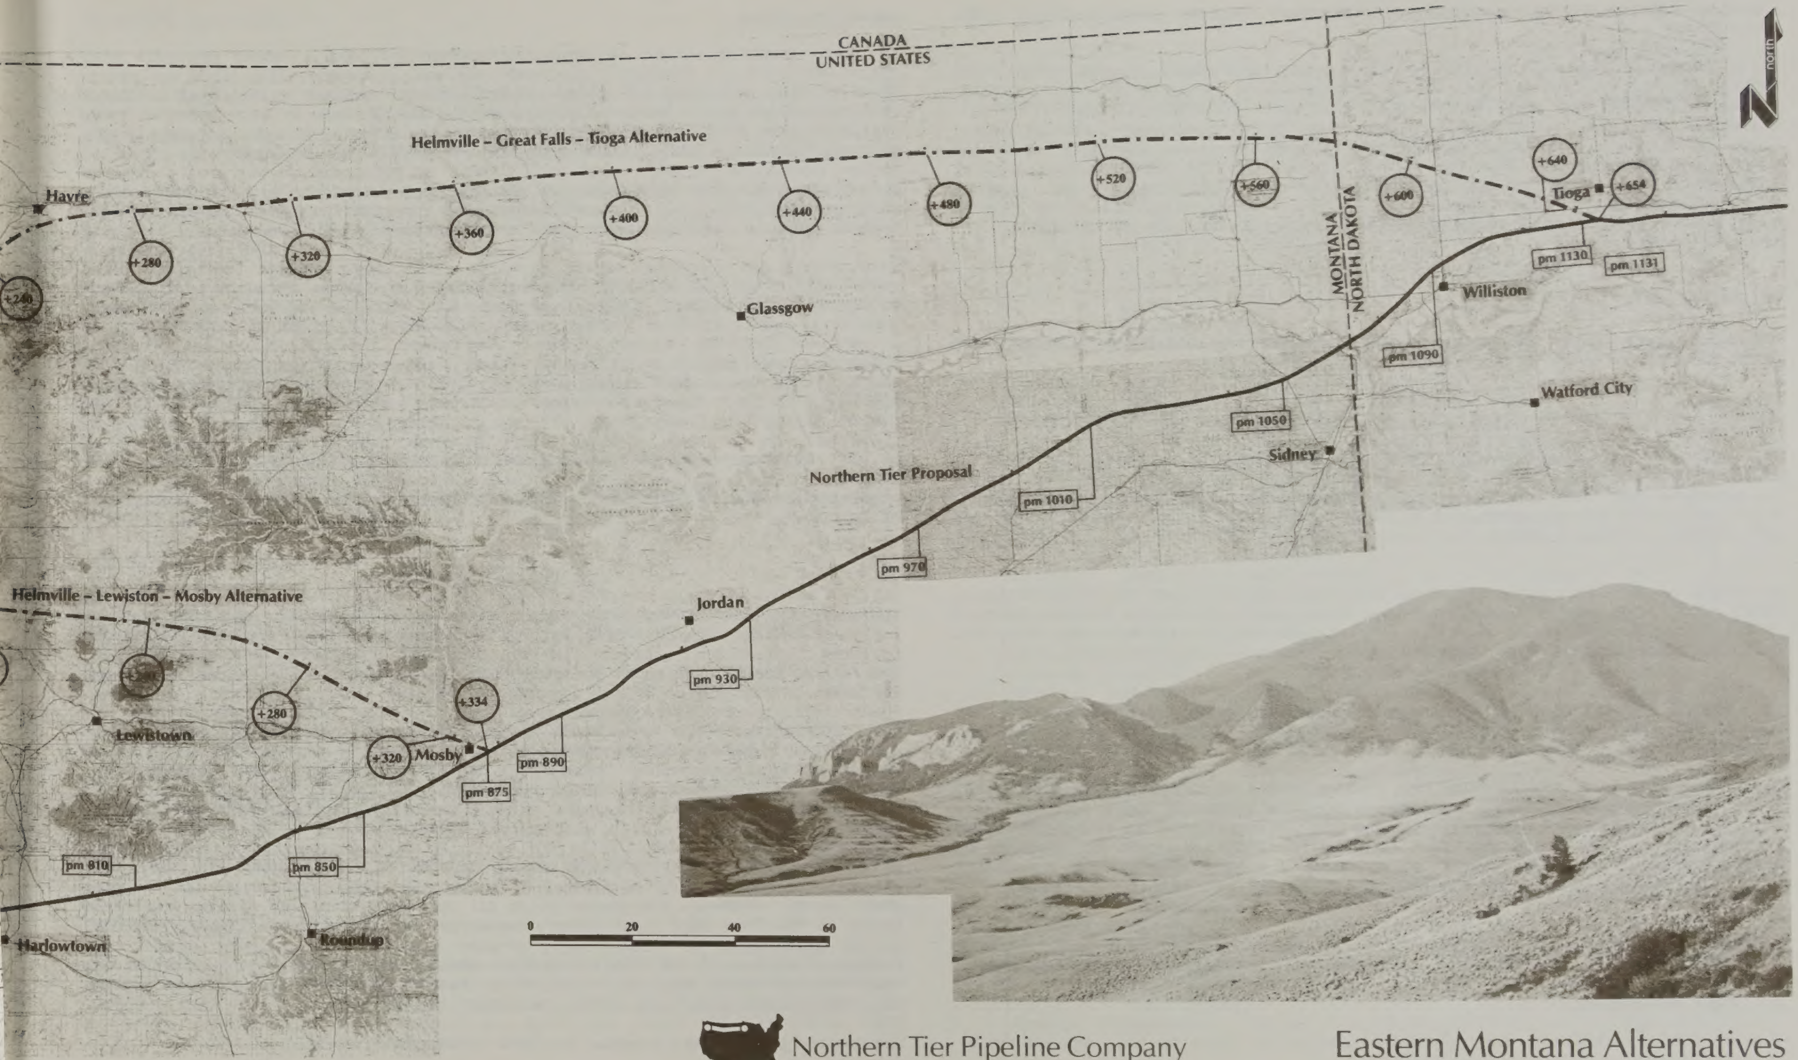

Northern Tier Pipeline Company

Eastern Montana Alternatives

(pipeline mile 633). Consequently, potential seismic impacts would be greater along the proposed route.

While potential slope instability problems occur along both routes, this route segment alternative contains more sites, both landslide and liquefaction. Potential landslide problems have been identified at Flint Creek (Garrison alternate route 42), Elliston Creek (pipeline mile 80), McDonald Pass (pipeline mile 85), and Broadwater (pipeline mile 95). Potential liquefaction problems have been identified along the Clark Fork River between pipeline mile 0 and 20, 30, the Little Blackfoot river (pipeline mile 65), Spotted Dog Creek (pipeline mile 70), Elliston Creek (pipeline mile 80), and Nelson Gulch (pipeline mile 110). Consequently, this route segment alternative, would have greater potential slope instability problems than the proposed route.

## Mineral Resources

The anticipated impacts to mineral resources would be the same for both the proposed route and this alternate route segment.

## Soils

From Missoula the route parallels the Clark Fork River for a distance of about 35 miles through undifferentiated alluvial soils. Depths to gravel, cobble, or bedrock is sometimes less than 2 inches. The route leaves the Clark Fork River for about 6 miles and passes through steep, hilly grasslands where soils are moderately deep and are gravelly, stony, or cobble.

Returning to Clark Fork River the route traverses both bottomland and foothill soils. After about 18 miles the route leaves the river and traverses the southern part of Powell County through soils on nearly level slopes and alluvial benches. Principal soils are deep loams and clay loams with slowly permeable clay loam subsoils.

The remaining 16 to 20 miles of the route to Helena passes through steep mountain slopes and hilly uplands with shallow to moderately deep loamy soils overlying limestone or granite bedrock.

Major impacts on soil would result from erosion losses on steep, unprotected slopes. Annual losses without protective vegetation would be approximatly 16 tons per acre. This would be reduced to less than 1 ton per acre per year when vegetation was reestablished. Soil compaction from construction equipment would be moderate on the predominantly loamy and gravelly soils. Loss of productivity would be no greater than an estimated 5 percent and should return to normal in 2 years.

Blasting and excavating the pipeline trench through the shallow soils would increase the potential for profile mixing and dilution. Without careful topsoil segregation and replacement natural soil fertility would be reduced by at least 10 percent and would be permanent.

Impacts from potential oil spills would be similar to those on the proposed route.

## Aquatic Resources

### Physical Components

The Clark Fork and Little Blackfoot Rivers exhibit seasonal variation of discharge with peak flows anticipated in spring and low-flow periods in late summer. Water quality of both rivers is classified as B-B, by the State of Montana, indicating very good water quality. Water can be characterized as calcium-bicarbonate type.

Ground water is generally limited to alluvial and glacial deposits in intermontane valleys within the area. Ground water generally isn't used in the mountainous regions; however, surface waters are directly supplied by ground water sources.

Construction and operation of the pipeline would impact surface and ground water resources. Increased sediment loads would occur in streams during and for a short time after construction. Cumulative effects from multiple crossings could intensify impacts if construction at crossings occured concurrently. The alignment parallels streams for over 90 percent of the route between Missoula and Helena, Montana. Sediment impact potential to streams exists from construction along most of this route. Hydrostatic test waters would be withdrawn from surface waters along the pipeline. Up to a 2 percent decrease in stream baseflow would occur if water were removed during mean flow periods.

No adverse impact would be anticipated from normal operation of the pipeline. However, in the event of a pipe rupture oil would be carried to surface waters, causing water quality degradation. Refer to chapter 3 for a more detailed discussion of impacts.

### Biological Components

The most important streams along this alternative route segment supporting fishery resources include the Clark Fork and Little Blackfoot Rivers. Numerous tributaries of these streams are crossed. The most important sport fish species found along this route include cutthroat, brook, brown, rainbow, and Dolly Varden trout, and whitefish.

These populations would be reduced through sedimentation of spawning gravel caused by instream trenching during construction and streambank erosion during the first years of project operation. Recovery of reduced populations should occur within a few years as vegetation became reestablished. If an oil spill occurred during project operation, fish populations would be reduced downstream for several miles. These reduced populations would also require several years to fully recover.

It is not known whether sediment related impacts to fishery resources along this alternative segment would be greater or lesser than those associated with the proposed route. However, the chance of an oil spill occurring and causing downstream losses to the Clark Fork River fishery resources--the most valuable fishery resources in the area--would be substantially greater than with the proposed route. The fisheries resource of the Little Blackfoot River (tributary to the Clark Fork River) would also be quite vulnerable to fishery losses since the river would be crossed twice and closely paralleled for approximately 10 miles.

See chapter 3 for a more detailed analysis of impacts.

### Terrestial Vegetation

This alternate segment, like the corresponding portion of the proposed route, is within the Douglas-fir ecoregion (see Map Addendum). Dominant overstory vegetation includes Douglas-fir, western larch, subalpine fir, and ponderosa pine. Range grassland vegetation, including blue bunch wheatgrass, needle and thread, and prairie pine grass, occupies the corridor primarily in river valleys. Riparian habitat, dominated by cottonwood and willow, is relatively common within this alternative segment. Where forest vegetation is absent or uncommon, riparian vegetation becomes a substantially more important component of the vegetative community. Riparian habitat becomes a major addition to vegetative diversity in areas where cropland or grassland is dominant. This alternate route would require removal of twice as much riparian vegetation.

The impact on riparian vegetation would be relatively substantial within this alternative corridor. About twice the riparian cover would be removed from this alternative than from the proposed route.

The impact on dominant forest vegetation is probably the most substantial impact of this alternative, because trees would not be permitted to mature on the right-of-way and because a substantial portion of the route is forested. Assuming that all forestland has about the same productive capability as the National Forest's crossed by the corridor, about 31 more acres of timber would be lost on the alternative route. Most of this loss would continue for the entire life of the project.

At this time no endangered or threatened species are known to occur within this proposed alternative route segment.

### Terrestrial Wildlife

Suitable peregrine falcon nesting habitat exists along the Clark Fork River, but no known eyries have been identified. Construction activities near nesting and/or roosting areas would be very disruptive during nesting and fledgling stages.

Impacts to wildlife habitat would include removal of forested wildlife habitat and removal of riparian wildlife habitat in national forests (USFS 1978). Most of the riverine habitat along the Clark Fork River drainage provides important white-tailed deer and elk winter range. Much of the private land contiguous to the national forests is rapidly being subdivided and becoming unsuitable for big game use. Impacts from additional removal of winter range by construction of the pipeline would increase dependence on the already heavily used winter range in national forests. Construction during late summer would reduce impacts.

Wintering waterfowl concentrations also use the valley lowlands of the Clark Fork River drainage. Summer construction would reduce disturbance to waterfowl.

### Cultural Resources

The cultural resource sites listed below would potentially be affected by this route segment alternative. Of these known sites the Mullan Road has been designated as a National Historic Civil Engineering Landmark. There is high potential for the discovery of additional archaeological and historical sites all along this route segment alternative. The currently known sites are listed in table 9.4-43.

TABLE 9.4-43 CULTURAL RESOURCES FOR MISSOULA-HELENA ALTERNATIVE

| County | Site Name | Site Type | Approximate Segment Pipeline Mile |
|---|---|---|---|
| Missoula | Lewis and Clark Trail (Lewis in 1806) | Early 19th century exploration route, a national historic trail | 1 |
| Missoula | Trail followed by Col. Gibbon to Battle of Big Hole | Nez Perce and U.S. military history | 1 |
| Missoula | Mullan Road | 19th century military, freight, and transport route | 1-80 |
| Missoula | 24MO1 | Prehistoric occupation | 15 |
| Missoula | 24MO13 | Prehistoric occupation | 15 |
| Missoula | 24M012 | Prehistoric occupation and visible traces of Mullan Road, a National Historic Civil Engineering Landmark | 16 |
| Missoula | 24MO1002 | Prehistoric occupation and visible traces of Mullan Road, a National Historic Civil Engineering Landmark | 17 |
| Granite | 24GN63 | Medicine Tree | 25 |
| Granite | 24GN2 | Prehistoric occupation | 25 |
| Granite | 24GN3 | Prehistoric occupation | 26 |
| Granite | 24GN64 | Burial | 26 |

TABLE 9.4-43 (Continued)

| County | Site Name | Site Type | Approximate Segment Pipeline Mile |
|---|---|---|---|
| Powell | Grant Cabin Site | Historic cabin | 61 |
| Powell | 24PW6 | Vision quest site | 77 |
| Lewis and Clark | 24LC102 | Historic mine Site | 83 |
| Lewis and Clark | Wasseiler Hotel and bathhouses | Social history listed in the National Register of Historic Places | 93 |
| Lewis and Clark | Broadwater Hotel and Spa | Social history | 94 |

Potential impacts to these known sites and to any presently unrecorded sites would be the same as those discussed in chapter 3.

Visual Resources

This route segment alternative traverses grasslands, forested and agricultural land, and parallels the Clark Fork River and Interstate 90.

Construction of a 90-foot right-of-way in this highly scenic and visually sensitive area would require clearing of trees, blasting of rock outcrops, cut and fill slopes, and construction of access roads in the foreground view of travelers on Interstate 90. The new rock and soil color exposed by cut and fill slopes, the contrast of form, line and texture of landform and vegetation would exceed visual resource quality objectives for class II and III and would constitute a severe adverse visual impact.

Proposed construction of the pipeline right-of-way in the congested Pinegrove-West Riverside area within the Interstate 90 right-of-way would be viewed in the immediate foreground zone by travelers on this highly used scenic highway. This exceeds the objective of subordination to the landscape, and would constitute a severe adverse visual impact.

Construction of the proposed pipeline along the Clark Fork River and the Little Blackfoot River could have moderate to high visual impact on travelers on Interstate 90 and U.S. Highway 12.

The impact should be substantially reduced after 1 to 2 years and persist as low for the life of the project.

Land Use

There would be approximately 1 mile of construction activity adjacent to residential areas on the fringe of Missoula. The anticipated impacts to this urban fringe area would likely be limited to the nuisance of noise, dust, visual disharmony, and traffic congestion, lasting for 1 to 2 weeks as described in chapter 3. Compared to the proposed route, this alternative would affect approximately the same amount of agricultural forest and rangeland.

According to Powell County land use plans, this route would be preferable to the proposed route because it follows Interstate 90 and other existing utility corridors.

Transportation and Utility Networks

In general, the impacts to transportation and utility networks would be as described in chapter 3. In some areas, however, impacts might be more severe than on the proposed route.

Construction activity through the urban fringe of Missoula would cause temporary traffic disruption and congestion.

The risk of physical damage to other utility systems would be higher on this route primarily because of construction through the narrow Clark Fork River valley east of Missoula where the pipeline would be parallel to and make several crossings of the Yellowstone Petroleum Products Pipeline, Montana Power Natural Gas Pipeline, electric transmission lines, and the Burlington Northern Railroad.

This route would require additional railroad crossings and crossings of Interstate 90. The number of other state and Federal highway crossings would be about the same.

The amount of new access road construction required would probably be comparable; however, there would be an estimated 8 to 10 miles less electric transmission line construction required to serve the pump stations. The impact to regional power supplies would be essentially the same as that of the proposed route.

Recreation

Southeast of Missoula an oil pipeline leak or rupture would affect anglers who fish the Clark Fork River. Missoula area residents have worked since the early 1970s to improve fishing quality in the Clark Fork River. The river is gradually returning to its original importance as a stream fishery of more than local interest. Man-days of fishing pressure from Missoula to Garrison was 9,764 in 1977 (Montana Department of Fish and Game 1978). Rock Creek, tributary to Clark Fork, is one of two blue ribbon fishing streams west of the Continental Divide. Oil pollution or construction/abandonment caused turbidity would affect fishing success for local anglers as well as out-of-state visitors.

Several camp and day use areas could be crossed by the pipeline centerline. Recreation such as fishing, float trips, picnicking, swimming, and camping occur along the Clark Fork River and along the Little Blackfoot River from Garrison to Helena (see Map Addendum for locations). The MacDonald Pass area, 15 miles west of Helena, receives high use year around. Present high scenic values would be degraded by pipeline construction in the MacDonald Pass area. The Continental Divide National Scenic Trail would be crossed. Impacts to recreationists would be significantly greater along this route alternative compared to the proposed route.

### Social and Economic Conditions

The route would cross through the counties of Missoula, Granite, Powell, and Lewis and Clark. Silver Bow County would be affected by this alternative since the cities of Anaconda and Butte could provide housing and services for pipeline workers. Impacts on these counties are discussed in chapter 3.

Granite County would receive the benefits of increased assessed valuation and property taxes. Short-term construction impacts from workers camping close to the route would be greater in Granite County than those resulting from the proposed route. Construction impacts would be decreased substantially, since few workers would reside in the county.

## HELMVILLE, GREAT FALLS, MONTANA TO TIOGA, NORTH DAKOTA

The Montana Department of Natural Resources developed this route segment as an alternate to the proposed southern route from Helmville, bypassing Helena and continuing eastward to the Montana border. BLM, for purposes of this ES, continued the route into North Dakota, paralleling the existing Portal Pipeline and rejoining the proposed route south of Tioga.

Beginning near Helmville at pipeline mile 597 this route segment would travel northeast across Helena National Forest, generally following State Highway 200 bypassing Great Falls on the west (figure 9.4-14). The route would continue northeast across private lands, cross State Highway 87 south of Havre and then extend eastward. The route would bypass the Fort Peck Indian Reservation on the north side and at Dagmar, Sheridan County, the route would head southeast and cross into North Dakota. Near Grenora the route would join the Portal Pipeline right-of-way and follow it to Tioga, rejoining the proposed route at pipeline mile 1,131. Total distance for this alternate route segment is 654 miles compared to 534 miles for the proposed route.

### Climate

No significant impacts on climate would be anticipated.

### Air Quality

Air quality impacts during construction would be about the same as those associated with the proposed route. No significant impacts would occur during the operation phase.

### Noise

Noise levels during construction would be about the same as those for the proposed route. A small number of residences would experience a temporary increase in noise levels. No significant impacts would occur during the operation phase.

### Topography and Geology

The topography of this route segment alternative would be essentially the same as that of the proposed route between pipeline mile 597 and 1,131 and would consist of moderate to steep mountains and intermontane tertiary basins in the western portion and a series of gently eastward-sloping terrace-like rolling hills, highly dissected badlands, and numerous north to northeast trending drainages in the eastern portion. Consequently, topographic impacts would be nearly identical.

Geologic material traversed by this route segment alternative would be similar to that encountered along the proposed route--Precambrian metasediments, Cretaceous marine sediments, Tertiary non-marine sediments, Mesozoic volcanic material, Quaternary alluvium, and some Quaternary glacial debris. Impacts as a result of construction (removal of between 8,600 cubic yards per mile in gentle terrain up to perhaps 250,000 cubic yards per mile in mountainous terrain and some change in the physical characteristics of the material) would be nearly identical.

#### Geologic Hazards

This route segment alternative would cross a region of moderate seismic activity corresponding to Seismic Risk Zone 2 (moderate earthquake damage expected) located in the portion of the route from Havre to the eastern end near Tioga, North Dakota. The proposed route would cross an area of high seismic activity corresponding to Seismic Risk Zone 3 (major earthquake damage expected) located in the vicinity of Helena, as well as regions of moderate (Seismic Rick Zone 3) and low (Seismic Risk Zone 1) seismic activity. Potential impacts from ground shaking would be greater along the proposed route. No active or potentially active faults (i.e., surface ruptures with apparent movement within the past 2 to 3 million years) have been found along the route segment alternative nor have any liquefiable sediments been found. Quaternary faults and zones of potential liquefaction may exist along this route segment alternative; but the lower seismic level would predict impacts lower than those along the proposed route.

Slope instability and outburst flooding hazards may exist along this route segment alternative but no locations have been identified. An assessment of comparative impacts is not possible.

#### Mineral Resources

The alternative would cross the Reserve coal field near Reserve, Montana, and a corner of the Avoca coal field near Tioga, North Dakota, and could interfere with coal recovery operations. The proposed route would cross the Avoca and Williston coal fields in North Dakota and Weldon coal field in Montana. Anticipated impacts on coal development would be the same.

## Soils

Soil disturbance and alteration would occur on almost 8,000 acres within the right-of-way compared to about 6,500 acres for the proposed route.

Detailed information on soils along the route is lacking. The following analysis is based on general reconnaissance soil survey reports published in 1932 and 1953. It is not possible to make accurate comparisions of resources and potential impacts.

Two physiographic regions, Rocky Mountains and Great Plains, would be traversed. Most of the right-of-way would be within the Great Plains region. More than 90 percent of the soils have a loamy surface texture which would enhance revegetation. Clayey subsoils are exposed on some soils and others have high clay content (460 acres). Combined with low annual precipitation, these conditions are not conducive to revegetation.

About 60 percent of the soils are fair to well-suited for farming. The Scobey and Williams soil series are well represented. At least 43 percent of the route would have moderate to high susceptibility to water erosion. Loss of topsoil could exceed 45 tons per acre per year in extreme cases. Most of the route would return to soil loss rates of less than 5 tons per acre per year once vegetation was re-established. Because of the predominantly loamy surface textures, moderate wind erosion would occur on most soils immediately following construction. Wind erosion losses exceeding 45 tons per acre per year could be expected on 6 to 10 percent of the route.

Other impacts would be similar to those that would occur along the proposed route segment.

## Aquatic Resources

### Physical Components

The largest streams crossed by the alternative route segment would be Nevada Creek, Blackfoot River (three crossings), Dearborn River, Sun River, Teton River, Marias River, Milk River, Poplar River, Big Muddy Creek, and Little Muddy River. Nevada Creek and the Blackfoot River are tributaries of the Clark Fork River; the other streams are tributaries of the Missouri River. More than 30 smaller streams would also be crossed. Water quality and discharge data has not been identified for streams along this route. Groundwater resource information has not been identified.

Construction of trenches across streambeds would disturb sediments, which would temporarily degrade water quality downstream from the crossings. Erosion from streambanks could contribute sediment to streams until revegetation occurs. An oil spill would degrade water quality for several miles downstream. Impacts on surface water resources along this route segment would be less significant than those along the proposed route.

### Biological Components

Fisheries resources have not been identified along this route segment, however, a few streams probably support one or more trout species, while many streams probably support warm water species including northern pike, walleye, catfish, sauger, perch, and crappie. Nearly all streams support forage fish such as minnows and sculpins.

Construction in the streambed and erosion from the streambank would contribute sediments which could damage trout spawning areas and reduce trout populations. Streambank erosion could continue during the operation phase until vegetation becomes reestablished. Since spawning areas have not been identified, it is not known to what extent trout populations would be reduced. An oil spill could reduce fish and aquatic insect populations for many miles downstream from the spill site Recovery of reduced fish population resuting from sedimentation or an oil spill could take several years. Impacts on fisheries resources along this route segment would be less significant than those along the proposed route.

## Terrestrial Vegetation

This alternative would cross the Douglas-fir ecoregion between pipeline miles 597 and 660, the Gramma-needlegrass-wheatgrass ecoregion between pipeline miles 660 and 1050, and the wheatgrass-needlegrass ecoregion between pipeline miles 1050 and 1251. The vegetation of these ecoregions is described in chapter 2. The vegetation types crossed by the alternate segment would be essentially the same as those crossed by the proposed route segment. The alternate would cross less forest land of the Douglas-fir region, however, and would require clearance of fewer acres of timber. The overall length of the pipeline would be increased by 120 miles under this alternative, thereby requiring an additional 1,309 acres of land. Areas of special concern include areas of near-pristine vegetation (grasslands), areas nominated by the state for natural areas because of their scenic, biological, or geological qualities, and habitats of plant species proposed for threatened or endangered status.

Near-pristine or relict vegetation stands within Montana's rangeland have been identified and inventoried by the Soil Conservation Service. Detailed studies of soil, climate, and vegetation have been conducted on these sites to establish ecological benchmarks upon which the condition of ranges which are being grazed can be compared with nature's potential. Each site is small, and protection is afforded through cooperation of the landowner (SCS 1973).

Four of these study sites are located near the pipeline study corridor.

The first site is the Helmville Cemetery, located 1 mile southwest of Helmville, Montana at pipeline mile 605. The site is on the edge of the 2-mile study corridor, and would be affected only in the event of a major oil spill in the area. The second site, located 2 miles southwest of Bowman's Corner along State Highway 200 (pipeline mile 670), is far enough away to have no adverse impacts, even from an oil spill. The third site, on top of Square Butte at pipeline mile 698, is elevated several hundred feet above the surrounding landscape and would not be impacted. The fourth site, located within the boundaries of the Benton Lake National Wildlife Refuge (pipeline mile 730), is also elevated several hundred feet above the proposed corridor, and is several miles north of it. No adverse effects to this site are expected.

The Montana Natural Areas Act of 1974 provides that a system of natural areas posessing scenic, biological, and geological features of educational and scientific value be established and protected. The pipeline study corridor comes within 2 miles of one such area 31 miles west of Great Falls. Crown Butte, an area covering 657 acres has been nominated as a potential Montana State Natural Area. Impacts to this area from pipeline construction would be minimal. An oil spill during pipeline operation might affect the area, though the probability of a spill reaching the area is remote. No plants which have been studied for nomination to Federal lists as threatened or endangered species are known to occur along the study corridor.

### Terrestrial Wildlife

Impacts of pipeline construction on wildlife along the north alternate would be of the same general character as those described for the proposed route in chapter 3. Wildlife areas of special concern along the proposed route (described in chapter 2) which would also be affected by this alternate include the Blackfoot River-Garnet Range area.

The Blackfoot River Canyon segment between Dalton Mountain and Lincoln Gulch (pipeline mile 613 to 623) is bald eagle habitat. Several sections owned by the U.S. Forest Service in this canyon have been proposed as "essential bald eagle habitat." Historical and potential peregrine falcon eyries can also be found along the Blackfoot River, though none are active at present. The peregrine falcon is an endangered species in the United States, and only one active eyrie is known to exist in Montana (Haynam and Sumner 1977). Additional activity along the river from construction and monitoring could force abandonment of eagle nests and prevent reintroduction of peregrine falcons.

The pipeline route between Lincoln and Roger's Pass (pipeline mile 626 to 648) traverses important grizzly bear habitat (Mealey et al. 1977). The grizzly, a threatened species in the United States, might be affected by construction noise and dust as well as airplane noise during monitoring and potential oil spills during operation. However, since the pipeline would follow the existing corridor along State Highway 200, impacts to the grizzly would probably be small. This area is also within the current range of the threatened northern rocky mountain wolf (NRMWRP 1978). Impacts to this species would be minimal. The proposed route does not pass through the range of either the grizzly or the wolf.

The Garnet Range-Blackfoot River area is elk habitat. The river lowlands contain important winter range for elk and deer. Elk, sensitive to disturbance, may be displaced for several miles from the corridor during construction.

Wildlife refuges and wetland marshes might be impacted by construction noise and dust. Also, monitoring of the pipeline every 2 weeks by airplane might discourage nesting of some species if the refuge or marsh is very close. Oil spills during operation might impact large feeding areas which would be lost for several seasons. Wildlife refuges potentially impacted include Benton Lake NWR (pipeline mile 730) and Hewitt Lake NWR (pipeline mile 980).

### Cultural Resources

Areas crossed by this route segment alternative have not been investigated for the purpose of identifying cultural resource sites.

### Visual Resources

This alternate would by-pass the Helena area and traverse less populated areas. It would have significantly less overall visual impact.

### Land Use

New wilderness study areas are lands selected for study as possible additions to the National Wilderness Preservation System (see chapter 2). They are managed to protect their wilderness values until studies are complete and land use recommendations implemented. Inventories of candidate roadless areas have been undertaken by both the U.S. Forest Service and the BLM.

Between pipeline miles 810-830 and 950-1030 are tracts of BLM land designated as roadless area inventory units. Seven of these wilderness study units would be crossed by the north alternate corridor (BLM 1979).

Only one of these units is being recommended for intensive inventory. Management policies mandated by Congress for these units while they are being studied would preclude a pipeline corridor through this unit. This management policy would apply between pipeline miles 1005 and 1025.

### Transportation and Utilities

The alternate route would include about 19 major highway crossings and 6 railroad crossings. Table 9.4-44 lists the highway and railroad crossings and approximate pipeline mileage.

Construction would cause short term disruption of transportation networks. The operation phase would not have significant impacts on highway or railroad transportation systems. These impacts would be similar for the crossings on the proposed pipeline route.

TABLE 9.4-44 RAILROAD AND HIGHWAY CROSSINGS ON HELMVILLE-TIOGA ROUTE SEGMENT ALTERNATIVE

| Highway or Railroad | Pipeline Mile |
|---|---|
| State Highway 200 | 608 |
| State Highway 200 | 613 |
| State Highway 200 | 631.5 |
| State Highway 200 | 645 |
| State Highway 200 | 647 |
| State Highway 200 | 651 |
| State Highway 200 | 652 |
| State Highway 287 | 670.5 |
| Great Northern Railroad | 717 |
| State Highway 89 | 717 |
| Burlington Northern Railroad | 845 |
| State Highway 87 | 845 |
| State Highway 2 | 904 |
| Burlington Northern Railroad | 904 |
| Harlem to Turner Highway | 910 |
| Great Northern Railroad | 980 |
| Opheim to Glasgow Highway | 1,039 |
| State Highway 13 | 1,101 |
| Flaxville to Poplar Highway | 1,115 |
| Burlington Northern | 1,156 |
| State Highway 16 | 1,157 |
| MT State Highway 50 | 1,181 |
| ND State Highway 85 | 1,205.5 |
| Great Northern Railroad | 1,238 |
| ND State Highway 2 | 1,240 |

### Recreation

This alternate segment avoids attractive and highly used recreational areas between the Continental Divide and Canyon Ferry Reservoir; both segments cross the Continental Divide National Scenic Trail. The alternate makes two additional crossings of the Lewis and Clark National Historic Trail (near Lincoln and Great Falls).

Other recreational activities would be impacted in similar ways for both the proposed and alternate route.

### Social and Economic Conditions

Population

The work force during peak construction periods in Cascade, Chouteau, Blaine, Phillips, Valley, Daniels, Sheridan, and Roosevelt Counties is provided in table 9.4-51. The estimated work force during construction or operation would not significantly affect county population totals.

Infrastructure

No significant adverse impacts would occur on infrastructural components.

Social Well-Being and Quality of Life

Negative effects on indicators of quality of life would occur from implementation of the proposed alternative. During construction rural land owners would have to adjust to construction activities. Their life styles would be altered temporarily. Construction activities, with associated noise, dust, and traffic pattern changes, would affect residential perceptions of the aesthetic setting, quality of air, and the region "as a place to live" during the construction phase. However, these would not be significant adverse impacts.

## HELMVILLE-LEWISTOWN-MOSBY, MONTANA

The Montana Department of Natural Resources proposed a short segment from Great Falls on the Helmville-Tioga alternative to Mosby on the proposed route. For comparison of the alternative to the proposed route, this analysis will pertain to the complete route alternative from Helmville to Great Falls and then to Mosby (see figure 9.4-14).

This route segment begins near Helmville, leaving the proposed route at pipeline mile 597, continuing northeast to a point south of Great Falls, then east past Lewistown, ending at Mosby, pipeline mile 875 (figure 9.4-14). Total distance for this segment would be 334 miles as compared to 278 miles for the proposed route.

### Climate

No impacts on climate would be expected.

### Air Quality

Air quality impacts would be about the same as those for the proposed route.

### Noise

Noise impacts would be about the same as those for the proposed route.

## Topography and Geology

Between pipeline mile 597 and Birdtail Butte (alternative route pipeline mile 685) topography and geology was previously discussed. From Birdtail Butte to the end of the segment near Mosby this route would cross terrain characterized by well-dissected badlands with moderate to gentle slopes and numerous north and northeast trending drainages. As the terrain is not quite as steep as that encountered by the proposed route resultant impacts, consisting of permanent landform changes, would be slightly less severe, generally ranging from 12 to 15 acres per mile (depending upon slopes).

Geologic material crossed by this route would be much the same as that encountered along the proposed route--Precambrian metasediments, Paleozoic and Mesozoic marine sediments, Tertiary nonmarine sediments, Quaternary glacial debris, etc. Geologic impacts--consisting of the removal of large volumes of geologic material (6,600 to 100,000 cubic yards per mile) and some change in the physical characteristics of the geologic material (porosity, permeability, moisture content, etc.)--would be slightly less due to the slightly gentler terrain.

### Geologic Hazards

Like the Helmville-Tioga alternative route, this route alternative would cross an area exhibiting two levels of seismic activity, a region of moderate activity corresponding to a Seismic Risk Zone 2 (moderate earthquake damage expected) located along the western portion of the route up to about Lewistown Segment pipeline mile 820 and a region of low activity corresponding to a Seismic Risk Zone 1 (minor earthquake damage expected) located between Lewistown Segment pipeline mile 820 and the end of the segment near Mosby (Lewistown Segment pipeline mile 930). As the proposed pipeline would cross an area of high seismic activity corresponding to a Seismic Risk Zone 3 (major earthquake damage expected) located in the vicinity of Helena in addition to regions of moderate (Seismic Risk Zone 2) and low (Seismic Risk Zone 1) seismic activity, the potential impacts from ground shaking would be greater along the proposed route. Like the Helmville-Tioga alternative, no active or potentially active faults or specific locations of potential liquefaction problems have been identified along this route alternative. While active or potentially active faults and zones of potential liquefaction problems might exist, the lower level of seismic activity would result in lower impacts than the proposed route.

Slope instability and outburst flood hazards might exist but no specific locations have been identified. An assessment of comparative impacts is not possible.

## Soils

Construction activity would disturb and alter soils on 3,370 acres of pipeline route right-of-way, compared to 2,836 acres for the proposed route.

Soils data are insufficient to make accurate and reliable comparisons of resources and potential impacts. The following analysis is based on data from a generalized reconnaissance soil survey published in 1953.

The route segment alternative crosses the Rocky Mountains physiographic region and the Great Plains physiographic region. Most of the route would be within the Great Plains region. Loam surface textures and clayey subsoil textures predominate. More than 30 soil series would occur along the route. The Pierre, Cheadle, Morton, and Lismas series appear to be the most prevalent. The Pierre and Lismas, as well as other soils, are high in clay content and are very difficult to revegetate. About 545 acres would fall into this category.

About 35 percent of the soils are rated fair to good for crop production under dry or non-irrigated conditions. Additional lands now marginal for farming would be fairly well suited to irrigated agriculture.

Removal of protective cover during construction would leave about 2,160 acres vulnerable to moderate and high soil losses from water erosion. Annual soil losses on long, steep slopes could exceed 45 tons per acre and would continue until vegetation was re-established. Effective revegetation would reduce soil losses to less than 5 tons per acre per year. About 250 acres would be highly susceptible to wind erosion until effective soil cover was re-established. Light soil blowing could also occur on the predominately loamy soils during the same period.

Other soil impacts would be similar to those along the proposed route segment.

## Aquatic Resources

### Physical Components

The largest streams crossed along this route segment would be Nevada Creek, Blackfoot River (three crossings), Dearborn River, Missouri River, Smith River, Belt Creek, Judith river, and Musselshell River. Nevada Creek and the Blackfoot River are tributary to the Clark Fork River, the other streams are tributary to the Missouri River. Several smaller streams would also be crossed. Water quality and discharge data have not been identified for streams along this route. Groundwater resource information has not been identified along this route.

Construction of a trench across the streambed would disturb sediments which would temporarily degrade water quality downstream from each crossing. Erosion from streambanks could contribute sediment to streams until revegetation occurs. An oil spill would degrade water quality for several miles downstream. Impacts on surface water resources along this route segment would probably be less significant than those along the proposed route.

### Biological Components

Fisheries resources have not been identified along this route segment; however, a few streams probably support one or more trout species, while many streams probably support warm water species including northern pike, walleye, catfish, sauger, perch, and crappie. Nearly all streams support forage fish such as minnows and sculpins.

Construction in the streambed and erosion from the streambank would contribute sediments which could damage trout spawning areas and reduce trout populations.

Streambank erosion could continue until vegetation becomes reestablished. Since spawning areas have not been identified, it is not known to what extent trout population would be reduced. An oil spill could reduce fish and aquatic insect populations for many miles downstream from the spill site. Recovery of reduced fish populations resulting from sedimentation or an oil spill could take several years. Impacts on fisheries resources along this route segment would probably be less significant than those along the proposed route.

Terrestrial Vegetation

This study corridor traverses 63 miles of the Douglas-fir ecoregion and 271 miles of the grama-needlegrass-wheatgrass ecoregion. Descriptions of these regions can be found in chapter 2.

This alternative route is approximately 56 miles longer than the comparable segment of the proposed route, thus requiring an additional 611 acres of land, assuming a 90-foot-wide construction corridor and flat terrain.

The initial 88 miles of this alternative is identical to that of the Helena-Tioga Alternate. The remaining 256 miles of pipeline corridor traverses vegetation comparable to the replaced segment of the proposed route, and impacts would be of the same general character as discussed in chapter 3.

The War Horse National Wildlife Refuge (pipeline mile 890) is located approximately 3 miles west of the corridor and is an important refuge for migratory waterfowl. No impacts to the vegetation of the refuge would occur during construction and normal operations. In the event of a major oil spill in the area, there is a remote possibility of damage to portions of the refuge.

No federally proposed threatened or endangered species are known to occur in the area traversed by the study corridor.

Terrestrial Wildlife

Impacts to wildlife from construction of a pipeline in this corridor would be of the same general character as discussed for the comparable segment of the proposed route in chapter 3.

Areas of special concern for the initial 88 miles of this segment are the same as those discussed for the initial leg of the Helen-Tioga Alternate.

This segment of the route encounters habitat for two endangered species, the bald eagle and the peregrine falcon, and two threatened species, the grizzly bear and the northern rocky mountain wolf.

The only areas of special concern identified along the remaining 271 miles of this alternative are waterfowl nesting areas along the Missouri River (pipeline mile 704) and in the War Horse National Wildlife Refuge (pipeline mile 890). Construction noise, dust, and associated activities could cause reduced nesting activity or abandonment of nests if pipeline installation occurs during the nesting season. Aerial surveys of the pipeline every 2 weeks for the 20-year life of the project would not be likely to disrupt waterfowl nesting activity if fixed-wing aircraft flying at an altitude of over 1,000 feet are used. Waterfowl are not expected to become habituated to the aircraft.

During operation of the system, the potential for oil spills within these critical areas exists. Should a spill occur near the War Horse NWR, it is unlikely that it would reach the refuge and directly impact the waterfowl. However, indirect impacts such as loss of feeding areas might be serious. It is also possible that a large pool of oil on snow or ice would attract waterfowl because it appears to be an open body of water (Barry 1970). This would potentially impact large amounts of waterfowl if the spill occurred during migration and was not detected for several days. Impacts to waterfowl from oil soaked feathers are widely known.

A spill within the Missouri River would destroy large amounts of shoreline vegetation used as nesting habitat, as well as directly impact waterfowl due to coating of feathers and ingestion of oil contaminated food.

The endangered whooping crane migrates through Montana, and thus might be affected by a spill. However, no nesting sites are known, so construction and normal operations are not expected to impact the species.

In certain areas, prairie dog towns might be encountered; however, no map is available showing their distribution. These towns provide habitat for the endangered black-footed ferret. Because of the nocturnal nature of this species, no accurate assessment of its distribution is available. Therefore, all prairie dog towns are considered potential habitat for the ferret.

Cultural Resources

The area crossed by this route segment alternative has not been investigated for the purpose of identifying cultural resource sites.

Visual Resources

Visual impacts for this alternate would be similar to the Helmville, Great Falls, Tioga alternate except for the crossing of Interstate 15 and the Missouri River--which could have a significant visual impact.

Land Use

Land use impacts would be similar to those which would occur on the proposed route.

Transportation and Utility Networks

This alternate route would have seven major highway crossings and four railroad crossings. Table 9.4-45 lists specific highway and railroad crossings and alternate pipeline mile locations. Construction and operation impacts at these crossing would be similar to those of the proposed route.

TABLE 9.4-45 RAILROAD AND HIGHWAY CROSSINGS

| Highway or Railroad Crossings | Alternate Pipeline Mile |
|---|---|
| U.S. Interstate 15 | 703 |
| Great Northern Railroad | 703 |
| State Highway 89 | 706.5 |
| State Highway 87 | 750 |
| Great Northern Railroad | 750 |
| Stanford to Arrow Cr. Highway | 789 |
| Chicago-Milwaukee-St. Paul and Pacific Railroad | 800.5 |
| Chicago-Milwaukee-St. Paul and Pacific Railroad | 838 |
| State Highway 191 | 863 |
| State Highway 191 | 869 |
| State Highway 20 | 921.5 |

## Recreation

This alternative segment would avoid the attractive and highly used recreational areas between the Continental Divide and the Canyon Ferry Reservoir; both segments cross the Continental Divide National Scenic Trail. This alternate segment makes two additional crossings of the Lewis and Clark National Historic Trail (near Lincoln and Great Falls). Other recreational activities would be similarly impacted by both the proposed route and the alternate route segment. Both proposed alternate segments make two crossings of the Lewis and Clark National Historic Trail.

## Social and Economic Condition

### Population

Peak construction work force estimates for Lewis and Clark, Cascade, Judith Basin, Fergus, and Petroleum Counties are provided in table 9.4-51. The number of persons who would accompany this work force into the counties would not significantly affect county population totals. The work force during the operation phase of the proposed project would not significantly affect population projections.

### Infrastructure

No significant adverse impacts would occur on infrastructural components of these counties during the construction or operation phases of the proposed alternative.

Bureau of Land Management

### Social Well-Being and Quality of Life

Negative effects on indicators of the quality of life would occur from implementation of the proposed alternative. During construction rural landowners would have to adjust to construction activities. Their life styles would be altered temporarily. Construction activities with associated noise, dust, and changes in traffic patterns would affect residents' perceptions of the aesthetic setting, quality of air, and the region "as a place to live" during the construction phase. However, these would not be significant adverse impacts.

## HARLOWTON-BEACH-CLEARBROOK

NTPC originally designated this segment as the proposed route but then changed to a northern alternative which parallels the Portal Pipeline right-of-way across North Dakota and Minnesota. Therefore this route segment is considered an alternative.

This alternative route segment begins at Harlowton, Montana, near pipeline mile 757 and travels in a northeasterly direction (fig. 9.4-1). The route enters North Dakota 5 miles south of Beach and crosses, northeasterly, rolling farm and grazing lands. Near Medora, the route crosses the Little Missouri National Grassland and the Little Missouri River. The route continues northeasterly from Medora, crossing Interstate 94 between Belfield and Dickinson and crosses the Missouri River about 15 miles north of Bismarck. A few miles east of the Missouri River, the route enters the "Pot Hole" or lake country. This area contains many lakes and wetlands and extends approximately 40 miles along the route. From the Kidder-Stutsman County line, the route continues in a northeasterly direction over level to rolling farmland, entering Minnesota near the town of Shelly on the Red River. The route traverses northern Minnesota for approximately 70 miles to the Clearbrook Delivery facilities, for a total distance of 692 miles compared to 735 miles for the proposed route

### Climate

No impacts on climate are anticipated for this alternative pipeline route.

### Air Quality

Air quality impacts would be similar to those for the other alternative route segments. During construction fugitive dust might be a problem under dry, windy conditions, causing localized high particulate levels.

### Noise

Noise impacts would be similar to those for the other alternative route segments. Since this alternative route traverses mostly rural areas, only scattered residences and some small residential areas would be affected by noise.

### Topography and Geology

This route segment alternative like the proposed route from the eastern boundary of Meagher County, Montana (pipeline mile 757) to the terminus at Clearbrook, Minnesota, is characterized by rolling hills, some highly dissected badlands, and hummocky glacial plains with numerous small glacial lakes. It does, however, contain longer stretches of badland topography (e.g., the Little Missouri River "breaks"). Consequently, topographic impacts, consisting of minor landform changes and drainage alterations, would be slightly greater than those along the proposed route.

Geologic material found along this route segment alternative would be essentially the same as along the proposed route, consisting of Cretaceous and Tertiary sediments, Quaternary glacial debris, and Quaternary alluvium. Consequently, impacts on the geologic material, consisting of the removal of large volumes of material and minor changes to their physical characteristics, would be the same.

### Geologic Hazards

As both routes would traverse an area of low seismic activity corresponding to a Seismic Risk Zone 1 (minor earthquake damage expected), containing no known active or potentilly active faults, anticipated seismic impacts would be the same.

Since this route segment alternative would cross terrain that is slightly steeper overall, particularly along the Little Missouri river (segment pipeline mile 306 to 335), a greater number of sites exhibiting potential slope instability problems have been identified--Sumatra (Harlowton alternate pipeline mile 125 to 127), Sand Creek (segment pipeline 205 to 207), Hunter Creek (segment pipeline mile 206 to 208), Bluffords (segment pipeline mile 271 to 272), South Fork Horse Creek (segment pipeline mile 284 to 291), the Little Missouri (segment pipeline mile 314 to 315 318 to 322, 326, 329 to 335, and 463), the Missouri River (segment pipeline mile 452), and Grass Creek (segment pipeline mile 463). Consequently, the anticipated impacts from slope instability would be greater than those along the proposed route.

### Mineral Resources

Although the proposed pipeline route would cross a portion of the Avoca coal field (Tioga, North Dakota) and Reserve coal fields (Reserve, Montana), this route segment alternative would cross the Wibaux coal field (Wibaux, Montana), which has a much greater development potential. Consequently, anticipated impacts would be greater along this route segment alternative. There is no significant difference in the impacts to other mineral resources found along these two routes.

### Soils

The silty clay or stony silt loam soils of east-central Montana would receive slight to moderate impacts. Wind-induced erosion would occur on approximately 650 acres because of temporary loss of vegetative cover. Soil loss from water erosion would be in the range of 6 tons per acre per year without protective vegetation and about 0.30 tons per acre per year with revegetated native grass.

Soils of the eastern Montana part of the route are primarily silty clay loams and silt loams. Areas of badlands with shaly, silty clay soils would be highly erosive. Such areas are dissected by numerous drainage channels and short steep slopes.

Exposed surfaces would lose an average of 21 tons of soil per acre per year that could be reduced to 1.2 tons per acre by revegetation with native grasses. About 550 acres within the right-of-way would be susceptible to moderate impact from wind-induced erosion.

Soils in the approximate western third of the route through North Dakota are shallow over soft sandstone and shale bedrock. Erosion, from both wind and water would be the major impact on the soils of this region. Soil losses from water erosion would average about 7.0 tons per acre per year without protective vegetation and 0.4 tons per acre per year after revegetation was complete. Moderate wind erosion losses would occur on approximately 300 acres within the pipeline right-of-way.

The route through central North Dakota traverses deep, well-drained soils, with loam, silt loam, and silty clay loam textures. Slopes are undulating to hilly. Average annual soil losses would be approximately 8 tons per acre in the absence of protective vegetation and about 0.4 tons per acre when vegetation is reestablished.

Soils of eastern North Dakota range in texture from fine sandy loam to silty clay loam. Surface relief is nearly level to undulating. Extensive areas are wet for several months at a time. Severe wind erosion occurs on the medium- and coarse-textured soils. About 60 acres would be affected. Soils of the Hamerly and Ulen series have high lime layers in the subsoil. Failure to segregate topsoil during trenching operations would result in reduced productivity. Gumbo spots have formed in some areas. These are small areas where the plow layer is soft and sticky when wet and very hard or extremely hard when dry because fine-textured, saline material from the subsoil has been mixed into the plow layer. Careful segregation and replacement of topsoils would be needed to avoid adverse impacts that would persist for many years. Impacts from water erosion with removal of vegetation would be less than 5 tons per acre per year.

In Minnesota the proposed route would traverse relatively flat, locally hummocky, terrain. The soils are mostly silty clay loams and silty clays. About 16 percent of the route has medium- and coarse-textured soils. Seasonally wet soils are those of the Fargo, Cashel, Colvin, Hegne, Shooker, Gonvick, and Flom series. Trenching activities in these soils in a saturated condition would adversely alter soil structure and reduce productive capacity for several years. Wind erosion susceptibility would be severe on about 120 acres. Soil losses by water erosion would be well below 5 tons per acre per year.

Impacts caused by soil compaction, soil profile mixing, and potential oil contamination would be fairly constant along the entire route segment. Soil compaction, except for the wet areas previously described, would cause temporary loss in soil productivity of 5 to 10 percent. Effects of compaction would last for about 2 years. These glacial and lacustrine soils have relatively thick, fertile topsoils. Segregation of only a standard 12-inch top layer would result in the replacement of some fertile soil material too deeply in the trench.

Impacts from potential oil spills would be similar to those aloong the proposed route.

## Aquatic Resources

### Physical Components

This alternate route segment crosses 15 major and over 300 minor streams within the Missouri River and Hudson Bay Basins. Major rivers that would be impacted by pipeline construction and potential oil spills include the Musselshell, Yellowstone Little Missouri, Heart, Green, North Branch Knife, South Branch Knife, Missouri, James, South Branch Goose North Branch Goose, Red, and Sandhill Rivers. In general, seasonal variations of streamflow occur. Peak runoff periods are in spring from rapid snowmelt; low flow periods occur in winter. Many of the smaller streams will cease flowing during the heat of the summer, and also during winter freeze. The Canyon Ferry and Fort Peck reservoirs limit seasonal variation of flow on the main stem of the Missouri. Water chemistry of surface waters varies from sodium-sulfate to calcium-bicarbonate type with moderately low to high dissolved-solids concentrations.

Ground water sources that could be impacted from construction and/or operation of the pipeline include the border, Great Plains, and central lowland regions. Aquifers most vulnerable to impact are generally shallow, unconfined, alluvium and terrace gravel deposits recharged by precipitation and/or stream runoff. The Fort Union and Lance formations are the most significant ground water sources along the alignment. Several towns including Roundup, Dickinson, Belfield, and Richardton use ground water for municipal supplies.

Impacts to hydrologic resources would result from construction and operation of the pipeline. Suspended sediment and siltation impacts would occur at and downstream of river crossing locations. Within about 1 month of construction the river should reduce its sediment load to preconstruction amounts. Hydrostatic test water would be withdrawn from surface waters along the alignment. A short-term decrease in baseflow would occur during withdrawal periods. Inadvertent discharge of hydrostatic test water could adversely impact receiving areas. If test water were of lesser quality than receiving areas, surface or ground water degradation would occur. Construction in shallow ground water regions would require trench dewatering. Ground water movement and water level would be impacted. Normal operation of the pipeline would have no major adverse impact. However, in the event of a pipe rupture, oil would be spilled and surface and/or ground water resources would be impacted. Water quality degradation would occur. Refer to chapter 3 Aquatic Resources--Physical Components, for a more detailed discussion of impacts.

### Biological Components

Streams along this corridor support warm water fishes. The most important sport species, including walleye, sauger, northern pike, catfish, perch, bass, and the sunfishes, are present in the majority of the larger streams along this route. In addition, the following concerns regarding specific rivers are noted:

Yellowstone: Important locally and regionally for sport fishing.

Little Missouri: Critical spawning area for the channel catfish populations of Lake Sakakawea are 15 miles downstream from crossing.

Heart: Important walleye and sauger spawning area downstream from crossing.

Green: Numerous springs and beaver dams assure fish survival in dry periods. Source of bait minnows for local sport anglers.

Knife: Good reproduction of sport and forage fishes.

Missouri: Highly valued sport fishery is considered one of the finest in Great Plains area.

James: Highly valued locally for its sport fishery.

Cheyenne: Highly valued sport fishery. Commercial fishery for bullheads, white suckers, and yellow perch in Lake Ashtabula, 15 miles downstream.

Sediment-related impacts would generally be expected to be minor to warm water fishery resources along this alternative route since most warm water species are adapted to waters containing high suspended sediments.

The greatest impacts would result from an oil spill that could reduce fish populations for several miles downstream from the spill site. The actual extent of oil exposure to fishery resources would depend on leak volume, detection and shutdown times, and on the stream characteristics at the time of the spill. Eggs, larvae, juveniles, and adult fish would be vunerable. The severity of impacts downstream could range anywhere from minor losses to the complete elimination of fish populations if spill volumes and oil concentrations were high, to no detectable losses if spill volumes and oil concentrations were low. If a large percentage of a specific fish population was eliminated, it might take several years to fully recover to prespill population numbers. Oil would be flushed out of streams quite rapidly but is likely to remain in downstream impoundments such as Lake Sakakawea and Lake Ashtabula for several months. Fish populations in these and similar impoundments would be expected to suffer greater losses than fish populations in streams. Impacts to fisheries along this alternative segment would be greater than those associated with the proposed route. See chapter 3 for a more detailed analysis of impacts.

Terrestrial Vegetation

In predominant grassland vegetation on the eastern half of Montana the initial short-term effect of construction would be less dramatic. Lower rainfall and higher evaporation rates would make revegetation more difficult. Potential for long-term negative impact on vegetation would be substantial.

Wetlands could have both long- and short-term significant adverse impacts resulting from construction caused siltation and drainage.

An oil spill would result in significant adverse impacts to vegetation if it occurred along riparian or wetland habitats. The specific impacts of an oil spill have been discussed in chapter 3.

In North Dakota, both short- and long-term impacts would stem from construction of the proposed pipeline. Badland and western grassland vegetation would be slow and difficult to reestablish because of the very low rainfall, about 10 inches per year (Shaver 1977). The low precipitation combined with high temperatures, high evaporation rates, and wind and water erosion would cause the terrestrial habitat to be sensitive to most physical disturbances. It is probable that long-term erosion would occur in the badlands and other western areas where slopes are steep, unstable, or stable only because of vegetative cover. After clearing, surface runoff and resulting erosion would increase and moisture infiltration would decline. Reduced soil moisture would further reduce the probability of successful revegetation. The impact on vegetation-wildlife habitat would be substantial in the badland-western grassland area of the state.

Riparian wetlands could also suffer a loss in productivity from increases in turbidity and silt loads caused by pipeline construction across streams. Accumulation of silt deposits form a soft semiliquid substrata inadequate for the anchoring of roots (Water Quality Criteria 1972). Blanketing of plants and sessile animals with sediment can cause drastic changes in aquatic ecosystems. If sedimentation covers substantial amounts of organic material, anaerobic conditions could produce noxious gases, low dissolved oxygen, and decreases in pH (Water Quality Criteria 1972).

Films of oil on the water surface might interfere with reaeration and photosynthesis. These impacts from an oil spill would mean a reduction in the productivity of the wetland habitat for mammals, waterfowl, and shorebirds as discussed in chapter 3.

Construction across the James River would increase siltation; deposition of this silt in the Arrowwood Wildlife Refuge could reduce productivity of these wetlands.

Most of the negative impacts on vegetation in Minnesota resulting from construction activities would be short-term. With revegetation, most negative impacts would cease. Overall adverse impacts would be insignificant because most of the land crossed by the proosed project are agricultural. Locally significant impacts would result from oil spills on riparian, wetland, or natural areas.

Selection of this alternative segment would result in the clearing of an estimated 2,844 acres of grassland-range, 48 acres of forest land, 607 acres of wetland, and 226 acres of riparian vegetation. Approximately 41 acres of forest land, 505 acres of wetland habitat, and 190 acres of riparian habitat would be maintained free of mature trees.

Locations of officially designated endangered or threatened species within the alternate pipeline corridor are not known at this time.

No known officially designated critical habitats occur within the proposed corridor in North Dakota.

No officially designated critical habitats are known to be crossed by the proposed project in Minnesota. However, the Agassiz Dunes Natural Area, owned by the Nature Conservancy and nominated as a unit in the Minnesota Department of Natural Resources Scientific and Natural Area Program, would be crossed by the pipeline. Construction impacts on natural vegetation could be locally significant. Burning, part of the area's management program to maintain existing vegetation, might not be compatible with pipeline operation.

Terrestrial Wildlife

Construction activities could reduce waterfowl habitat and production in areas near Lake Mason National Wildlife Refuge and Charles Russell National Wildlife Refuge. Marsh drainage and disturbance of nesting and staging areas could cause abandonment of nests and a concommitant short-term loss of the waterfowl harvest along the borders of these wetlands. Except for the prairie pothole region in North Dakota, disturbance impacts would generally be minor and short-term. However, any wetland drainage would represent a permanent loss of waterfowl habitat. Waterfowl concentrations in the prairie pothole region involve approximately 245 miles of corridor.

Unknown numbers of grouse and other shrub dependent species occur throughout the corridor. Specific areas of concern include the disturbance of sage grouse strutting grounds near Dry Creek and Nelson Creek, and sharp-tailed grouse dancing grounds near Timber Creek in McCone County; other important ground habitats occur near Williston, Stanley, and Essex. Impacts from disturbance would be low and of short duration unless vegetation was radically altered.

Prime pheasant and white-tailed deer habitat would be disturbed along the Flat Willow stream crossing in Petroleum County, Montana, and at other minor stream crossings. Removal of riparian habitat is expected to be short-term with minimal effects on wildlife.

Prairie dog towns occur near the Charles Russell National Wildlife Refuge and may provide suitable habitat for the black-footed ferret, an endangered species, although no ferrets have been identified in the area.

Cultural Resources

The cultural resource sites listed below would potentially be affected on this route segment alternative. Specific localities of known paleontological resources have been identified only for the North Dakota portion of this alternative. There is high potential for discovery of additional archaeological, historical and paleontological sites all along this route segment alternative.

The currently known prehistoric, historic and paleontologic sites are listed in tables 9.4-47, 9.4-48, and 9.4-49.

Potential impacts to the known sites and to any presently unrecorded archaeological, historical, and paleontological sites would be the same as those discussed in chapter 3.

Sharp-tailed grouse U.S. Fish and Wildlife Service

| Stutsman | Invertebrate fossils and microfossils | 537 |

## Visual Resources

The proposed alternate route begins about 14 miles to the northwest of Harlowton and proceeds in a north-easterly direction. The topography is flat to rolling hills, covered by sagebrush and juniper, with deciduous trees and shrubs in the drainages. Most drainages are intermittent. The pipeline would cause minimal visual intrusion except for high visual impact during construction.

Short-term adverse visual impacts could be expected during construction. The visual impact would be reduced considerably within a short time, and remain low for the life of the project.

A massive oil-spill during operation could create high impact for a short time. Depending on extent of spill, recovery of land to agricultural quality would require about 2 to 3 years. Low visual impact would exist after the disturbed right-of-way had been revegetated.

## Land Use

This alternative route would have significantly less impact on urban land uses than the proposal because it would not be adjacent to any small communities; the proposed route is adjacent to 19 small communities. For other land uses, there would be approximately 570 acres less agricultural land and about 110 acres more rangeland disturbed by construction. In North Dakota, where land with prime farmland soils has been mapped by the Public Utilities Commission, this alternate route would have significantly less impact, approximately 465 acres within the construction right-of-way as opposed to 1,190 acres on the proposed route. However, tile drainage systems in Norman County, Minnesota, would be disturbed. The impacts would be as described in chapter 3.

This alternative route would have more adverse impacts on lands with special management concerns than would the proposed route. Both lands included and proposed for inclusion in the Lake Mason National Wildlife Refuge in Musselshell County, Montana, would be traversed by the pipeline as would several Waterfowl Production Areas (WPA) and U.S. Fish and Wildlife Service wetland easements in North Dakota and Minnesota. The U.S. Fish and Wildlife Service policy is to discourage uses of these areas which do not complement their primary function, which is waterfowl production. This alternative route would also conflict with Forest Service management guidelines for the National Grasslands as it would cross river breaks and river bottom ecosystems.

A potential adverse impact to wilderness resources might occur in Prairie County, Montana where the route would cross through an undeveloped area of public lands known as the Terry Badlands. This area is being studied by the Bureau of Land Management for its wilderness characteristics. Interim management would forestall pipeline construction or any other action which might detract from wilderness values.

This alternative would also adversely impact the Lake Aggasiz Dunes Natural Area in Polk County, Minnesota, and might be in proximity to several natural areas or potential natural areas in North Dakota.

Through North Dakota this route would conflict with local government guidelines by not following cadastral subdivision lines (north-south, east-west). Instead it would pass diagonally through the land ownership pattern and would not utilize existing transportation or utility corridors.

## Transportation and Utility Networks

The potential for adverse impacts to other transportation and utility systems would generally be reduced on this alternative route because of the fewer number of crossings and miles of parallel construction. However, near Center, North Dakota, the pipeline would be in proximity to a high voltage direct current (HVDC) transmission line, which under a ground fault condition, could induce dangerously high voltage to the pipeline. Aside from this hazard, which would require special engineering design to counteract, the impacts to other networks would be similar to those described in chapter 3.

Slightly less electric power would be needed for operation of the pipeline system on this route because of the 25 miles less distance required. This difference would not be significant in terms of regional power supplies and the amount of new electric transmission facilities required would be about the same as for the proposed route.

## Recreation

Recreation east of Harlowton is dispersed with few developed camp or destination sites. Big game is hunted throughout most of the area in eastern Montana. In addition, game birds are hunted in the vicinity of Roundup. The possibility of reduced game harvest, a result of construction and abandonment activities, would affect few recreationists because of the amount of hunting areas available. East of the Missouri River in North Dakota the Prairie Pothole lakes area is a valuable waterfowl resource. Several wildlife refuges are be in the vicinity of, or crossed by this alternative. Recreationists would experience a degraded resource as a result of the construction or abandonment activities. In the case of an oil pipeline leak or rupture, there might be permanent loss of portions of the resource in the Prairie Potholes region.

Angler pressure is variable. Streams of importance to sport fishers are the Yellowstone River, James River, Missouri River, and Cheyenne River. Anglers and other recreationists in the Dickinson vicinity who fish or otherwise enjoy the Heart River or Patterson Lake might find a lower quality resulting from use by construction crew members. Visitor use of Patterson Lake was 192,000 recreation days in 1975.

Recreationists using the Theodore Roosevelt Memorial Park (South Unit), or travelling through North Dakota to view the National Grasslands (see Map Addendum for locations) would experience degraded vistas and lessened quality as a result of the pipeline corridor.

Recreation in Minnesota is mainly fishing, hunting, and water related sports. The numerous fields available for hunting and lakes for fishing and other water-related recreation in western Minnesota would make any losses to these activities as a result of pipeline construction operation and abandonment activities minor and similar to those of the proposed route.

## Social and Economic Conditions

Counties through which the pipeline would pass are identified in table 9.4-50. The counties which would sustain social and economic impacts during construction are identified in tables 9.4-50 through 9.4-54.

Impacts to these counties would be similar to those sustained in the counties impacted by the proposed route. Temporary increases in population would occur during construction from influxes of construction workers and workers in other industries and their families. The probable distribution of the construction work force is shown in table 9.4-51. These data are shown in terms of the number of man-months during each subdivision of the construction period. The data for the local construction work force represents workers living at home during their employment. Table 9.4-52 shows total employment including the additional employment generated in the area by construction activity, and table 9.4-53 shows the amount of personal income generated, including construction payrolls.

In Montana the following counties would sustain high construction impacts with temporary population increases in excess of 5 percent: Wheatland, Golden Valley, Petroleum, Musselshell, Rosebud, Custer, Dawson, and Wibaux. Impacts would be about the same in Wheatland County as those for the proposed route. They would be lower in Fergus, Petroleum, and Garfield Counties, but higher in the other counties listed in the tables than those for the primary route. Impacts in Custer and Dawson Counties would be increased in severity because of concurrent energy development activity in these counties.

In North Dakota, no counties would have temporary population increases in excess of 5 percent, however, impacts from pipeline construction would be high since they would coincide with coal development activities in Dunn, Stark, Mercer, Oliver, Morton, McLean, and Burleigh Counties.

In Minnesota, Norman, Clay, and Mahnomen Counties, none of which are impacted by the proposed route, would have minor construction impacts. Counties impacted by this alternate route would have similar or lower impacts than those for the proposed route.

Source: Montana Department of Revenue, North Dakota Office of State Tax Commisioner, Minnesota Department of Revenue.

Note: Property taxes were calculated on January 1977, construction cost values. Major facilities including pump stations were assigned to the counties in which they were located, and pipeline values were distributed on the basis of volume-miles. Individual pump station values were estimated by distributing the total construction value among stations in accordance with station horsepower, features, and pipeline size. In Montana assessed values were calculated separately for facility value (situs property) at a common local assessment ratio of 8.55 percent, and for pipeline property at the state utility ratio of 16.0 percent.

Property tax collections computed at recent levy rates are shown in table 9.4-54. All impacted counties except the following would receive increased revenues during the operation of the pipeline: Fergus, Petroleum, Yellowstone, Garfield, Treasure, McCone, Dawson, Richland, Fallon, and Cascade in Montana; and Morton, Sheridan, Wells, Eddy, Ramsey, Nelson, Barnes, Grand Forks, Cass, and Ward in North Dakota; and Clay, Red Lake, and Mahnomen in Minnesota.

## GRAND FORKS, NORTH DAKOTA

On February 21, 1979, the North Dakota Planning Division, Bismarck, requested BLM to include an alternate route segment bypassing of Grand Forks, North Dakota and East Grand Forks, Minnesota. This alternate route was recommended by the City of Grand Forks Planning and Zoning Commission on February 7, 1979 to avoid environmental impacts upon the cities' water supply, to reduce impact upon prime agricultural lands, and to eliminate one major river crossing of the Red Lake River.

The Grand Forks alternative leaves the proposed route at pipeline mile 1,375 west of Grand Forks, North Dakota and continues directly east across the Red River about 4 miles north of the city (figure 9.4-15). In Minnesota the route turns southeast, bypassing East Grand Forks, Minnesota, rejoining the proposed route at pipeline mile 1,426. This alternative eliminates the proposed underwater crossing of the Red Lake River and crosses the Red River below Grand Forks and East Grand Forks, eliminating potential crude oil contamination of the cities' water supply. Total distance for this alternative is 54 miles compared to 51 miles for the proposed route.

This route segment would reduce construction impacts on prime farm lands and alleviate potential crude oil contamination of the Grand Forks city water supply. Although the route alternative is about three miles longer, it would cross less prime agricultural land. This would reduce impacts on agricultural production during the short term construction period.

The alternate route would cross the Red River north of Grand Forks. This would eliminate one underwater crossing for the Red Lake River, which would reduce potential construction impacts upon water quality and resident fisheries. Crossing the Red River downriver from Grand Forks eliminates the potential crude oil contamination of the Grand Forks city water supply and also alleviates the associated public concerns.

## 9.5 Alternatives of Northwest Energy Company Proposal

### PORT AND ONSHORE FACILITIES ALTERNATIVES

#### SKAGWAY ORE WHARF

It is technically feasible to upgrade the existing ore wharf (figure 9.5-1) to receive 120,000 dead weight tonnage (dwt) tankers; however, a number of considerations make this an undesirable alternative. The berthing slip has limited maneuvering space and its use would create traffic congestion problems for other vessels which utilize the port area. The present volume of ore carrier traffic, plus the size and frequency of tanker arrivals, would increase the level of berth occupancy to over 60 percent. Even if tankers arrive on schedule, a berth occupancy in excess of 60 percent makes ship demurrage a source of concern. Moreover a large scale dredging operation would be required that would involve the removal of a substantial amount of contaminated material, lead, and zinc, and the location of a suitable site for disposal.

#### SINGLE POINT MOORING

This alternative requires a swing radius of approximately 2,000 feet. In order to provide the swing diameter which the tankers require, the mooring device would have to be placed in the center of the 6,000-foot wide channel. Channel water depth at this point averages 450 feet, which is too deep for efficient operation of the mooring device. In addition, a single point mooring cannot match the high unloading capacity of a shore-based terminal, and is more vulnerable to oil spills because long-floating and submerged flexible oil lines.

#### YAKUTANIA POINT

This alternative, differing in location from the preferred alternative, has limited feasibility. Property currently designated as a city park would be used and the extreme steepness of the harbor bottom could pose major problems in wharf construction.

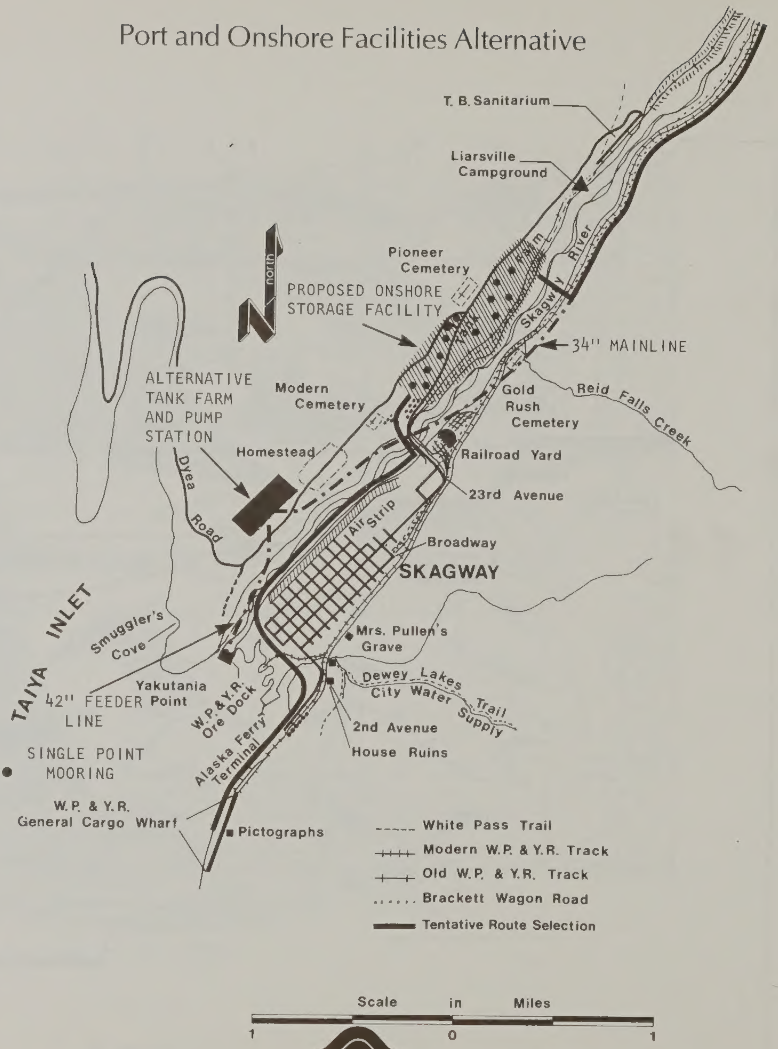
#### HAINES

Haines, Alaska is located on Portage Cove near the north end of Chilkoot Inlet. It is the point of origin for the Haines Road to the Alaska Highway and a petroleum pipeline to Haines Junction.

The city of Haines is built on a narrow, low-elevation neck on the Chilkoot Peninsula. Otherwise, its physical setting is somewhat similar to that of Skagway. The granitic and metamorphic bedrock is thinly mantled with colluvium and beach deposits of reworked colluvium. Thick alluvial deposits are probably not present.

Topography is more gentle in Haines than in Skagway, with forested lower slopes of 0 to approximately 25 degrees and as much as 30 degrees in some locations.

The Chilkoot Inlet-Chilkat River fault system passes approximately two miles west of Haines and roughly parallels the Haines Road, crossing it several times on the way to



Port and Onshore Facilities Alternative

Northwest Energy Corporation

Figure 9.5-1

Haines Junction. A magnitude 6 earthquake occurred on or near this fault approximately 15 miles northwest of Haines on March 9, 1952.

The port facility would be constructed adjacent to deep water at Haines and the oil would either be transferred to barges or pumped through an underwater pipeline and transported fifteen miles to Skagway.

Both transportation methods would involve oil spill risks not present in the primary proposal. Additional handling required by barge transport would increase the frequency of routine oil spills and the probability of a major spill. Moreover, additional tankage at Haines would probably be required.

A Haines-Skagway pipeline located on the bottom of Taiya Inlet could be subject to additional risks of underwater slides, particularly those that might be triggered by earthquake movements disturbing the steep front of the submerged portion of the Skagway River delta. The existence and extent of other smaller submerged deltas cannot be confirmed or ruled out at this time. Leak detection and repair would be considerably more difficult in the case of an underwater pipeline in a fjord of more than 600 feet depth.

### YAKUTANIA POINT ONSHORE STORAGE FACILITY ALTERNATIVE

Yakutania Point would be the only other site in the Skagway area for location of the onshore storage facility. However, the slope is relatively steep in this area and the terrain is rough. Storage tanks would have to be benched and notched into the side of the mountain. Part of the site area is within city limits and part is under the jurisdiction of the Federal government. A portion of the city-owned section is currently designated as a city park. There are also some homes built or under construction within the site area which would have to be relocated.

### ROUTE SEGMENT ALTERNATIVE

### SKAGWAY-CARCROSS HIGHWAY

A route following the Skagway-Carcross Highway was evaluated as an alternate to following the railroad right-of-way. The Skagway-Carcross Highway was opened for service in the spring of 1979. According to the Haines-Skagway Area Land Use Plan (ADNR 1979), "... the highway corridor will be managed for the dual values of transportation and scenic quality, with the emphasis on transportation. Access across or along this corridor is allowed, including pipelines...". In view of this statement, the corridor was examined as a viable alternative.

The miles of pipeline needed for this route and that needed for the proposed route along the railroad right-of-way would not be substantially different. Both would have about 14 miles of pipeline in Alaska and 5 miles in Canada up to the point where they meet. From that point the route could either follow the highway or the railroad right-of-way.

The following differences would result from use of the highway route segment:

Assuming a 90 foot wide construction corridor, this route would require an additional 55 feet of cutting into the hillside compared to 75 feet for the proposed route.

Assuming 100 percent slopes, the amount of excavated material would be 1.0 million cubic yards per mile compared to 1.2 million for the proposed route.

Requires no crossings of the Skagway River, while the proposed route would have three crossings.

Requires no removal of existing services, while the proposed route would need removal of the Canol pipeline and the utility lines presently in the railroad right-of-way.

Would not disrupt train service, whereas the proposed route would disrupt train services for one season.

Would not alter historic scene of railroad; would add to existing highway scar which is visible from the railroad.

Route passes through approximately 1 mile of Park Service land in the southwest corner of the White Pass unit.

Would disrupt highway traffic during summer tourist season while construction is occurring, whereas the proposed route would not.

Would require year-round maintenance of roadway for inspection of pipeline; this road is presently not maintained in winter, whereas the railroad is kept open year round.

Would require standard equipment for pipeline construction compared to special equipment needed for the railroad route.

Land cleared would vary from 90 - 200 acres, depending upon terrain, compared to 125 - 290 acres for the proposed route.

Would probably not affect the proposed Warm Pass Ecological Reserve.

Would not affect the historic Brackett Wagon Road.

## DELTA JUNCTION SYSTEM

The Delta Junction oil transporation system is presented as an alternative to the proposed system through Skagway, Alaska. The section includes a brief description of the proposed alternative together with the preliminary design parameters. This description is followed by a preliminary analysis of the existing environment of the Alaskan portion of the alternative route, and the analysis is in turn followed by a preliminary discussion of issues arising from a consideration of pipeline construction and operations along the designated corridor.

In this system, 500,000 barrels per day of Prudhoe Bay oil would be diverted from the 48-inch Alyeska pipeline into Northwest Energy's storage facilities at Alyeska Pump Station No. 9, Delta Junction, Alaska (figure 9.5-2). The oil would then be transported to Keg River via a new pipeline and then through existing systems to Edmonton and to ultimate markets in the U.S. This alternative system would use a 34-inch pipeline, but a smaller line (30 or 26-inch) may be preferred in the final analysis. This alternative 34-inch system would cost $1,376 million.

A Delta Junction to Keg River connection would result in 1,119 miles of new main line, with some 85 miles constructed above-ground. Because this alternative has no connection for offshore oil supplies it would be entirely dependent on Prudhoe Bay supplies of crude oil.

The oil would be received from the suction side of the Alyeska Pump Station No. 9 and delivered into the first pump station of the Alaska Highway System for transporation to Keg River and Edmonton. The continuity of service of the proposed pipeline would thus be dependent upon the ability of the Prudhoe Bay facilities to maintain supply and upon the Alyeska pipeline system to deliver that supply. A minimum of 2 days' storage should be provided at the supply source in order to minimize short-term fluctuations in the pipeline supply. This would be equivalent to 1 million barrels of storage. Thus, four 250,000 barrel storage tanks (or equivalent), complete with appropriate mixing and pumping equipment, would be required at the interconnection with the Alyeska pipeline at Alyeska's Pump Station No. 9.

No additional storage facilities would be provided at Edmonton. Thirteen pump stations would be required in total, located as follows:

| Location | Number | Horsepower - ISO 1/ |
|---|---|---|
| Alaska | 3 | 58,500 |
| Yukon | 6 | 117,000 |
| British Columbia | 4 | 78,000 |
| | | 253,500 |

1/ 50 percent standby installed

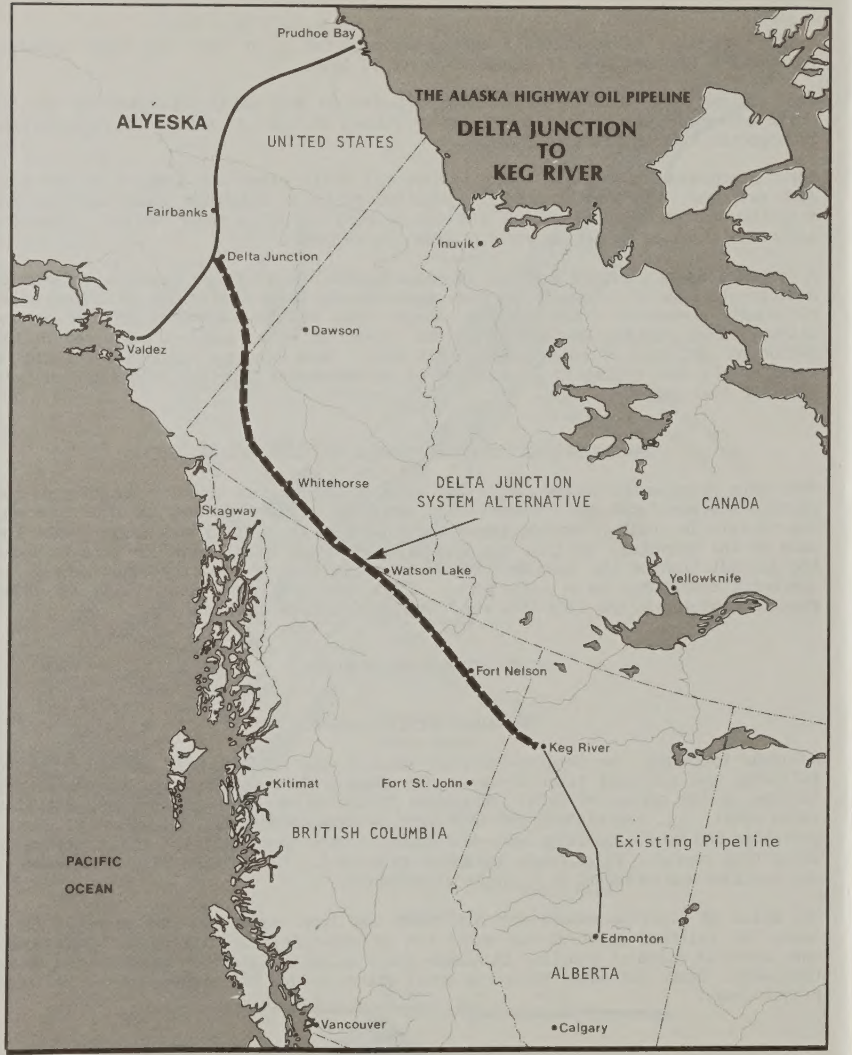


Figure 9.5-2 Delta Junction System Alternative

The starting point of this alternative oil line route would be at Pump Station No. 9 on the Alyeska pipeline, approximately 7 miles south of Delta Junction, Alaska. The route initially would head easterly for 19 miles until reaching the Alaska Highway, and then southeasterly paralleling the Alaska Highway and the approved Alaska Highway Gas Pipeline Corridor for 186.4 miles to the Alaska-Yukon border. The route would remain in the Tanana River Valley throughout this traverse of the Tanana-Kuskokwin lowlands below the east face of the Alaska Range. Six major rivers, the Gerstle, Johnson, Robertson, Tok, Tanana and Granite, would be crossed.

The route would continue in a southerly direction following the approved Alaska Highway Gas Pipeline Corridor, would cross Beaver Creek and would roughly parallel the Haines-Alaska pipeline, crossing the White River.

From the White River, the route would take a more southeasterly direction. After crossing the Koidern River at pipeline mile 236, the route generally would parallel the Alaska Highway, again crossing the Koidern River and the Donjek River downstream of the existing highway bridge.

After this crossing, the route would proceed across a plain located between the Kluane Range and the Kluane River. The settlement of Burwash Flats lies east of the route.

From Burwash Flats, the route would lie to the west of and generally parallel to the Alaska Highway, crossing the Duke River. The route would pass the settlement of Destruction Bay.

The oil line route would diverge from the gas pipeline right-of-way and follow along the east side of the Kluane Range, just west of the highway which follows the west shore of Kluane Lake.

Slims River would be crossed upstream of the existing bridge and causeway. The route would proceed around the south side of Klaune Lake and would depart from the lake and the highway. Several small creeks would be crossed in this next section. The oil line would again follow the approved route of the Alaska Highway Gas Pipeline, continuing in a more or less direct route to the southwest corner of Pine Lake.

The routing would continue from this point in an easterly direction, lying north of and generally parallel to the Alaska Highway. The village of Champagne is located approximately 2 miles from the pipeline route.

The Takhini River would be crossed and the route then would take a major diversion from the highway and would proceed through a pass to the north of Mouth Ingram. The route would be located approximately 4 miles southwest of the Whitehorse Airport. The routing would continue through the pass crossing the White Pass & Yukon Route railway at its east end, and the Yukon River. The Yukon River crossing would be approximately 1.2 miles downstream of the existing highway bridge.

The route would generally parallel the Alaska Highway and join the proposed Skagway to Keg River route.

In the following sections, a survey is made of the existing corridor proposed for the Delta Junction Alternative pipeline route through Alaska. As described earlier, this corridor is the one approved for the Alaska Highway Gas Pipeline Project, extending from Delta Junction along the Alaska Highway route to the Canadian boundary.

### Climate

The Continental zone of Interior Alaska lies south of the Central Brooks Range of mountains and inland from the coastal maritime zone. The route of the proposed alternative pipeline system lies entirely within this zone. Summer and winter temperatures are extreme and precipitation is low. Except for a few isolated locations, surface winds are light. Annual precipitation averages 10 to 14 inches. The wettest month is July, or in some cases June. Annual snowfall averages 33 to 54 inches. Snow cover continues from October through April at most locations, with the higher elevations carrying snow cover well into May and June. Average snow depth in winter is normally less than 24 inches, but maximums of 50 to 60 inches are on record for Big Delta and Northway.

Surface winds, as registered by wind recording stations near or along the pipeline route at Big Delta and Northway, are light. This description is generally representative of the sections of route near these two centers. This, however, is not necessarily true of wind direction. The terrain exerts a strong influence on wind direction by channeling through valleys, making the direction at a station applicable only to its immediate vicinity. This is demonstrated by the effect of the Tanana and Delta river valleys on directional frequencies of wind at Big Delta. Average windspeeds are also increased by the effects of channeling at Big Delta.

Mean annual "equivalent chill" temperatures are 14.9°F at Big Delta and 19.2°F at Gulkana. January is the coldest month for that portion of Alaska southward of the Brooks Range. July is the warmest month for all locations.

### Air Quality

In general terms, the portion of Alaska under consideration as a prospective oil pipeline route may be regarded as an area of naturally occurring high air quality. Even here, however, the normal contents of the atmosphere and the characteristics of its circulation are manifested in terms of their effects on visibility and on capacity for dispersion.

In those areas south of the Brooks Range with elevations below 1,000 feet, ceiling and visibility of three miles or better occur 93 percent of the time. At locations like Fairbanks, for example, wintertime fog is a factor. At the higher elevations of

Big Delta and Northway, winter fog is considerably less frequent due to more winds, low level mixing of the air, and fewer sources of condensation nuclei for the formation of fog.

Some of the areas traversed by the proposed pipeline route are protected from the prevailing winds by ranges of mountains. These "orographic" effects together with such phenomena as thermal inversions, barometric highs and lows, and "Chinook" type winds all occur in varing degrees along the route. Such occurrences result in ice fogs, or "white-outs", bizarre wind storms and extremely low temperatures in the Alaskan interior.

For an atmospheric pollutant to increase its concentation in a given location, vertical mixing of the air must be stopped by a temperature inversion and, given the condition, the situation will be aggravated by a lack of horizontal mixing and/or by the presence of surrounding high ground. Some of the valleys south of the Brooks Range and along the proposed pipeline route represent areas which, when affected by temperature inversions and/or conditions of calm, may trap and retain atmospheric pollutants.

In spite of the generally good atmospheric quality over this area of Alaska, localized sources of atmospheric pollutants do exist. These are for the most part, connected with human settlements and involve vehicles, both residential and commercial heating facilities, and power generation facilities.

In addition to noxious pollutants produced by internal combustion engines, water vapor is produced, which in turn leads to the formation of ice fog. The occurrence of ice fog can often be related to organic fuel combustion which provides both moisture and nuclei for its formation.

## Noise

No data covering noise are known to be available for the parts of Alaska that would be crossed by the proposed oil pipeline system. It is generally conceded, however, that objectionable noises are rare.

## Topography and Geology

A portion of the proposed pipeline route lies within the physiographic unit known as the Yukon-Tanana Uplands. A belt of highly deformed Paleozoic sedimentary and volcanic rocks containing conspicuous limestone units, overthrust and overturned to the north, extends along the north side of the upland. The rest of the upland is chiefly Precambrian schist and gneiss but has scattered small elliptical granitic intrusions in the northwestern part; large, irregular batholiths make up much of the southeastern part. In the western part a thick mantle of windborne silt lies on the lower slopes of the hills, and thick accumulations of "muck" (a mixture of frozen organic matter and silt) overlie deep stream gravels in the valleys.

The proposed pipeline route would enter the Yukon-Tanana Uplands south of Hess Creek and leaves it at Shaw Creek Flats. The route is underlain by reworked windblown silt, colluvial silt, sand and rock fragments, alluvial silt, sand, gravel and dune sand. Locally, the unconsolidated deposits are absent or occur as a thin veneer over bedrock which consists chiefly of schist dolomite, limestone, granite and volcanic rocks.

In the Tanana-Kuskokwin Lowlands, the outwash varies from coarse gravel near the Alaska Range to sand and silt along the axial streams. Areas north of the axial streams are underlain by thick deposits of muck. Parts of the southwestern portion of the lowland have thick loess cover, but the central and eastern parts are free of loess south of the Tanana River. Scattered low hills of granite, ultramafic rocks and Precambrian schist rise above the outwash. Tertiary conglomerate in the foothills of the Alaska Range plunges beneath the lowland in a monocline, and the heads of the outwash fans may rest on a pediment cut across the conglomerate. The base of alluvial fill in the Fairbanks area lies at or below sea level.

The succeeding portion of the proposed pipeline route begins at Shaw Creek and ends at the Canadian border. Geological units to be traversed include frozen ice-rich silts over alluvial gravels from Shaw Creek across the Shaw Creek Flats, frozen silt (loess) over bedrock (schist) from the southern end of Shaw Creek Flats to the Tanana River, and generally thawed gravels and sands of alluvial origin in the Tanana River Valley to the boundary.

The Tanana Valley is underlain primarily by unconsolidated sediments probably several hundred feet thick; the maximum recorded thickness is 200 feet adjacent to the Canadian border. The most extensive unconsolidated materials are broad alluvial fans of sand and gravel. Overlying parts of these fans are moraines composed of coarse to fine-grained soils. Finer-grained deposits, primarily poorly-drained silt high in in content of organic material peat, occur adjacent to the floodplain, and in the lowlands southeast of Tetlin Junction. These materials are generally soft and wet during the summer but firmly frozen during the winter. Larger but discontinuous deposits of sand and gravel are available from the river bars, which are inundated during the spring. Most of the surficial materials are covered by loess.

Alaska lies along the northern edge of a vast, continuous, seismically active belt that circumscribes the Pacific Ocean basin and parallels the Alaska and Coast Ranges and the Aleutian Islands. In spite of this, however, the proposed pipeline route southeast of Delta Junction traverses a region of relatively low seismicity. The closest recorded large earthquakes have occured approximately 100 miles norhtwest of Delta Junction near Fairbanks. A few epicenters of earthquakes measuring 2 on the Richter scale were reported near the corridor southeast of Delta Junction.

A local fault extends some 25 miles from Clearwater Lake, in the Big Delta quadrangle, southeastwards to the Gerstle River in the Mt. Hayes quadrangele. It consists of a series of parallel to sub-parallel, north-facing escarpments, with minor right slip and a normal-slip component of the south side up. The fault would be crossed by the pipeline route south of the Tanana River.

Southeast of Big Delta, there is no known surface evidence of active faults crossing the Tanana Valley. There is, however, some evidence of two linear zones of seismicity that may be related to subsurface faults.

### Soils

Soil is continuous over the Alaskan land surface except for the steep, rugged mountain peaks and areas of perpetual ice and snow. Topography and drainage influence soil development by affecting soil moisture temperature and stability. Sheer, mountainous areas preclude soil development. The rapid drainage of knolls, ridges and steep slopes depresses plant growth; hence soils are shallow and low in organic matter. On the more gently sloping lands, soils retain moisture and plant growth is better. Poorly-drained lowlands may receive so much surface water that muskeg and swamp areas form. Permafrost impedes internal drainage of the soil profile and thus arctic soils are considered immature. Tundra and bog soils are common and widespread.

The Yukon-Tanana Upland is characterized by broad, undulating divides and flat-topped spurs; the ridges have crest altitudes of 1500 to 3000 feet and rise 500 to 1500 feet above adjacent valley floors. The ridges and valley sides have a mantle of colluvial and wind-blown (loess) silts. The major valleys are floored with alluvial sands and gravels which commonly have a thick covering of organic silts. On the steep hill slopes and ridge crests, the colluvium is shallow, generally less than 4 feet thick. The major soil types are: loose-to-dense colluvium with windblown silts; wet organic silts predominatly in low-lying areas; and dense sand and gravel alluvium (e.g., floodplains of the Salcha River and in the vicinity of Ross Creek).

The Tanana-Kuskokwin Lowland comprises a broad depression bordering the Alaska Range on the north. Wet loams with thick overlying peat and permafrost occupy lowland areas along rivers. Other poorly-drained soils occupy lower slopes adjacent to valley bottoms in the Tanana Valley. Their texture becomes more gravelly at higher elevations. Well-drained brown, loamy soils overlying gravelly-to-sandy materials occupy terraces, outwash plains, and low hills in the Tanana Valley near the Kantishna and Nenana Rivers, and occur in association with sandy soils of dune areas along the Kantishna. These brown loams also form in the upper valley from the Delta River to Tok in association with wet soils of lower slopes.

A layer of volcanic ash, 2 to 6 inches thick, is found in profiles of the Northway Junction area, material deposited approximately 14,000 years ago by an eruption within either the Wrangell or St. Elias Mountains.

Along the proposed pipeline route, moderately deep and well-drained brown upland soils are most extensive. Gravelly-to-sandy brown soils occupy moderate to steep slopes along the upper Tanana Valley from Big Delta to the boundary, and are shallow to moderately deep over gravelly parent material and bedrock.

Stratified sandy alluvial soils occupy river terraces along the Tanana River in the Birch Lake areas. Wet, loamy soils with a thick over-lying peat layer occupy low areas along drainages, extending to low gravelly slopes of the uplands along the upper Tanana. The major soil types are: moderately-dense to dense silts over dense sand, locally overlain by thin (5 feet) organic-rich silt; loose, wet, organic-rich silt to a 10-foot depth, over sand and gravel; dense alluvial sand and gravel (e.g., floodplains and terraces of the Tanana and Delta Rivers).

Many of the soils traversed by the proposed pipeline route are characterized by "permafrost". Local variations in thickness, areal extent, and soil temperature depend on differing thermal properties of earth materials and on local differences in climate, topography, vegetation, geology, hydrology, glacial history and rate of heat flow within the earth. In many places such local variations mask the regional southward decrease in areal extent and thickness and southward increase in permafrost temperatures.

In the Yukon-Tanana Upland, south of Fairbanks, much of the surface soils material is thawed; however, there are large accumulations of ice in some of the sediments, especially the fine-grained, reworked silt.

With respect to the route through the Tanana-Kuskokwin Lowland, permafrost is generally continuous from Shaw Creek to the Tanana River, and discontinuous in the Tanana River Valley. The permafrost table is highly variable, ranging from 2 to 20 feet, but locally depressed as much as 40 feet near the Chena River. The active layer varies from 0 to 2 feet, but extends to as much as 6 feet in sand and gravel. Segregated ice is rare and when present (in silts) is in the form of crystals, coatings, seams and sometimes wedges. Little or no visible ice is present in sand or gravel.

The predominately coarse-grained deposits of the Tanana Valley, which are the most extensive, are generally underlain by numerous isolated masses of permafrost more than 25 feet below the surface, and extending to recorded depths of 90 to 209 feet. Scattered lenses of permafrost, in the hills composed of loess and sand, are 2.5 to 3.5 feet below the surface. In the finer-grained deposits containing silt, organic soils and peat, the permafrost is usually 1 to 3 feet below the surface, except in the immediate vicinity of streams or ponds.

### Aquatic Resources

#### Hydrology and Water Quality

The pipeline would cross a portion of one of the major hydrologic regions of Alaska, the Yukon region, and for the major part of that traverse lies within the Tanana subregion. Most water storage is provided by the winter snowpack. While the proposed route does not lie near the termini of any glaciers, there are active glaciers at the headwaters of rivers tributary to the Tanana. These glaciers store tremendous amounts of water and many of the streams draining into the Tanana are glacier-fed.

Mean annual runnoff ranges from one cubic foot per second (cfs) per square mile in the Tanana subregion lowland to four cfs per square mile in the Alaska Range. Mean annual peak runoff ranges from about 10 cfs per square mile in the lowlands to 50 cfs per square mile in the Alaska Range and the uplands of the Upper Yukon-Tanana boundary. Most annual peaks occur in summer from rainfall, although spring snowmelt can also cause annual peaks. Low flow is usually in late winter or early spring, following the winter streamflow recession. Mean annual low monthly runoff ranges from between 0.2 cfs per square mile in the Tanana subregion lowlands to 0.3 cfs per square mile in the Alaska Range. Streams in many small basins probably freeze completely during most winters. During winter, when there is little or no snowmelt or rain, the large contribution to streamflow is groundwater discharge in the channels of the larger rivers.

In the Upper Yukon region, all surface water sampled has been of the calcium bicarbonate type of acceptable quality. A few of the streams carry excessive iron content during part of the year.

Surface water sampled in the Tanana is of acceptable quality for public supply. Although concentrations of dissolved solids range from 60 to 484 milligrams per litre (mg/l), most samples are less than 200 mg/l. The dissolved solids content is highest in water from areas adjacent to the mountains and decreases in water from areas toward the center of the basin. Water sampled near the center of the basin has the highest concentration of dissolved solids during periods of low flow, when groundwater discharge is probably greatest. The streams flowing from the Alaska Range are generally higher in sulphate and magnesium content than the others, but none contain excessive amounts.

Suspended sediment concentration in Alaskan streams has been recorded for less than 5 years, which is not highly reliable for predictive purposes. In general, nonglacial streams transport less than 100 mg/l of suspended sediment during May through October, in contrast to as much as 2,000 mg/l for glacial streams. Nonglacial streams often transport their highest concentrations during spring melt from May through June, with other peaks occurring in August through September. Glacial streams transport their highest concentration during heavy glacial melt, usually in middle or late summer, but also carry high concentrations during spring snowmelt. During fall and winter, glacial and nonglacial streams both carry less sediment than in summer.

For nonglacial streams draining into the Tanana River, normal summer concentration of suspended sediments range from 10 to 300 mg/l. Normal summer concentration in the Tanana River range from 10 mg/l in the headwater to more than 1,000 mg/l downstream. Concentrations during the winter are generally less than 20 mg/l for all streams measured in this basin. The average annual sediment yield of the basin ranges from less than 100 tons per square mile in the mountains north of the Tanana River to perhaps 5,000 tons per square mile in the Alaska Range.

Glacial-outburst flooding is a potential occurrence in the Tanana subregion. Glacier-dammed lakes are waterbodies at least partially contained by glacier ice. The lakes usually form when a depression either on or adjacent to a glacier, a pocket beneath it, or a valley blocked by a glacier is filled by rain and runoff from melting snow and ice. At some critical point, the water erodes a channel through or beneath the ice and the lake drains rapidly. The resulting floods have sharp, sudden peaks. Glacier-dammed lakes form initially, may break out and never refill, or the filling and draining cycle may be repeated many times.

Recent unfrozen alluvial deposits in river valleys, including floodplains, terraces, and alluvial fans, are the principal groundwater aquifers along the proposed pipeline route. Aluvium, consisting largely of permeable sand and gravel, ranges in thickness from a few feet in small mountain valleys to 2,000 feet in the Tanana Valley. Glacial and glaciolacustrine deposits in the interior valley are a much smaller source of groundwater near the proposed pipeline, but the older consolidated bedrock is capable of small yields from fractures and is used locally for water supply in the Yukon/Tanana uplands. Groundwater also occurs in cavernous carbonate rocks that support large springs near the pipeline route.

Recharge of principal alluvial groundwater reservoirs along the proposed pipeline route occurs largely through the unfrozen zones underlying streams. The most important source of groundwater recharge in the Tanana Basin is seepage from streams. Seepage losses from streamflow in Jarvis Creek near Big Delta average 10 cfs per linear mile of channel.

Discharge of groundwater from principal alluvial aquifers along the proposed route occurs largely as base flow discharge to streams. Groundwater is also discharged at springs, lakes and wetlands and directly by evapotranspiration from shallow groundwater reservoirs.

In the Yukon hydrologic region, the alluvial deposits of the Tanana subregion have the highest potential for groundwater yields in Alaska, exceeding 1,000 gallons per minute (gpm) in the floodplains. Upland deposits yield less than 100 gpm.

Surface icing occurs throughout the proposed pipeline corridor. Masses of ice may be formed by the overflow and subsequent freezing of sheets of emerging groundwater and springs. No one factor alone, but a complex interaction of several factors control the incidence of icing. At any given site, topographic, geologic, hydrologic, and meteorologic factors determine the dynamics, regime and magnitude of the icing process. Icings form on streams when channel ice thickens and restricts flow; hydrostatic pressure increases so that water breaks out, spreads and freezes, causing icings to thicken throughout the winter as successive ice sheets accumulate. Thick floodplain icings commonly form on the shallow channel of braided rivers. Icings also form along shallow channels where winter streamflow is sustained by groundwater. Large springs are the source of major icings in some river valleys. Small springs and seeps of groundwater form small upland or hillside icings.

## Fisheries

Surveys indicate that the fishes of the Tanana River watershed apparently overwinter in the clear river waters flowing beneath the thick surface ice. As early as mid-April adult grayling move upstream into the thawing streams. They are followed by immature grayling and perhaps some whitefish. The grayling spawn as soon as the streams are ice-free and the water temperatures rise, in May or June. The adults leave the small tributaries immediately after spawning, remaining in the more silt-free downstream waters. The fry remain in the small tributaries until late August or September. A general downstream movement occurs in fall, as glacial melting is retarded and silt load in the rivers is reduced.

Round whitefish and humpback whitefish behave similarly, but their upstream movement occurs later. The downstream movement apparently is sychronized with that of the grayling.

Northern pike and turbot also ascend the streams in spring, but their movement is not as extensive and many fish remain in the tributaries near the river or in adjacent sloughs.

The life history of Dolly Varden of the small tributaries in this area is not well understood. Since this species is a fall and winter spawner, its downstream migration may occur under ice in winter. It is believed that completely frozen streams may sometimes force Dolly Varden, perhaps accompanied by grayling and whitefish, to overwinter in perennial springs.

Little is known of the other less abundant species in the Tanana River above Delta Junction. The chum salmon that spawn in the area are few and most are seen in late August and September. Both historical and more recent observations, though admittedly limited, have suggested that a few salmon spawn throughout the upper Tanana River, but there are no major concentrations.

## Terrestrial Vegetation

The proposed pipeline corridor would traverse five broad vegetation types within the Tanana river valley. Plants of this region are subject to some of the greatest climatic extremes in North America. The principal trees characterizing the transcontinental boreal forest reach their northern limits in this region. Interactions of severe climate, repeated fires, discontinuous permafrost and braided drainage systems have produced a complex vegetational pattern.

The Bottomland Spruce/Poplar Forest is primarily composed of white spruce locally mixed with balsam poplar. The best white spruce stands are on level floodplains and low river terraces. Balsam poplar represents a successional stage leading to a mature forest with ferns, grasses, lichens, herbs and mosses. The forest type is confined to level, broad floodplains, low river terraces, and the more deeply-thawed south-facing slopes of major rivers. The above type is found extensively along the Tanana River and is somewhat less extensive along its major tributaries.

The Upland Spruce/Hardwood Forest is a fairly dense forest of white spruce, paper birch, quaking aspen, and balsam poplar. Black spruce usually replaces white spruce on north-facing slopes and poorly drained flats. White spruce occur in mixed stands on south-facing slopes and well-drained soils and may form pure stands near streams. Paper birch and quaking aspen stands, usually an early stage of succession following fire, tend to be even-aged and more uniform in size than spruce stands. Aspen and birch predominate on well-drained southern slopes. Under growth in this type normally consists of mosses and grasses on drier sites and brush on moist slopes.

This is the most extensive vegetation type in the Yukon Region. Treeline extends from 2,000 to 3,500 feet along the Alaska/Yukon boundary to 2,000 feet on southern slopes of the central Brooks range. White spruce becomes scattered among high brush as treeline is approached.

The Lowland Spruce/Hardwood Forest of evergreen and deciduous trees is dominated by black spruce which sometimes forms extensive pure stands. It is a slow-growing species, but can invade burns rapidly. Slow-growing stunted tamarack are associated with black spruce in wet lowlands. Rolling basins and knolls in the lowlands support various mixtures of white spruce, black spruce, paper birch, quaking aspen and balsam poplar. Bogs and muskegs occur on lower ground. Undergrowth may include willow, dwarf birch, various shrubs, grasses, ferns, horsetail, lichens and sometimes a thick cover of mosses.

This forest type occurs extensively on shallow peat, glacial deposits and outwash plains in intermontane basins and on lowlands and north-facing slopes thoughout the Yukon Region. It occurs at elevations ranging from sea level to 1,500 feet in higher basins and lowlands to more than 2,500 feet on north-facing slopes.

Extensive bogs occur on poorly drained soils where conditions are too wet for tree growth. Bog vegetation may consist of sedges, mosses, shrubs and berry bushes, resin birch, dwarf birch and willow. Some low-lying saturate soils support conttongrass tussocks surrounded by shrubs. Widely-spaced and stunted spruce and tamarack may occur on higher ground. Bog surfaces in the region often have uneven, string-like ridges (string bogs), usually too wet to support shrubs.

Muskegs occur primarily in unglaciated areas, old river terraces, outwash plains, filling ponds and sloughs and occasionally on gentle, north-facing slopes.

Moist tundra consists of a varying mixture of cottongrass tussocks and dwarf shrubs. Associated species are grasses, sedges, mosses, horsetail, low-growing willows, dwarf birch, and a few berry bushes. This type occurs sporadically in the foothills of the Brooks Range with some representation in elevated areas of the upper Tanana drainage.

Alpine Tundra occurs on ridges and rocky slopes where bedrock is close to the surface. The soil is usually coarse and shallow and contains little humus. Alpine tundra is most common at elevations between 2,000 to 4,000 feet. Vegetation is usually sparse and seldom more than a few inches high. White-mountain areas and lichens usually dominate, along with low-growing herbs, grasses, sedges, and both resin and dwarf birch.

### Threatened and Endangered Species

No plants which have been proposed for federal status as threatened or endangered species are known to occur within the Tanana river valley.

### Ecological Reserves

Of the 233 units proposed as reserves throughout Alaska, two are located in the Tanana River Valley where pipeline construction and operation may affect them.

The Healy Lake and River system located approximately 30 miles east of Delta Junction is one of the proposed units, and Robertson River, located approximately 20 miles northwest of Tanacross, is the other. Detailed descriptions of the reserves are being prepared but are unavailable at present. There has also been no discussion of boundaries of these units in the literature. Boundaries will probably be set after there has been a decision on which units to include in the system.

The Healy Lake and River is under private ownership and has undergone minor development, with cabins located around the lake shore. If included in the reserve system it will remain in private ownership, with no change in plans for development or otherwise.

The Roberston River is presently under state ownership and has had no previous development, except where the Alaska Highway crosses it about 1 mile east of its junction with the Tanana River. No change in ownership or development policies is anticipated should the river be included in the reserve system.

## Terrestrial Wildlife

Highly productive of wildlife are the basins of the Yukon and Tanana rivers. The Minto Flats and Tetlin Lake vicinities are centers of high production for water-oriented animals and birds. Interspersed scrubby timber, brush, marsh and muskeg throughout these interior valleys also support upland species.

Less productive are the surrounding highlands. Many are covered with unbroken spruce forests and support few animals. Red squirrel and pine marten, which can meet all their habitat needs in this single type, are exceptions.

Some species, like the wolf, wolverine, and raven, thrive in a broad range of conditions at any season, and may be found almost anywhere in the region that provides adequate food. Others, such as the moose and many passerine birds during migration, are confined to one habitat type for nesting or winter feeding, but they utilize a broad range of habitats at other seasons. Other species, as for example the red squirrel, ruby-crowned kinglet, and the beaver, are adapted only to a narrow range of habitats.

The broad valleys of the Tanana River drainage covered with mixed spruce/hardwood and mukeg/bog vegetation, in combination with river islands and bars covered with young willows, provide an intermixture of habitat types favorable to numerous woodland mammals. Most species found in wooded habitats occur in reasonable abundance, although the numbers of certain species in particular areas may vary in response to habitat changes such as fire or to hunting pressure.

Caribou use a variety of habitats, but the best winter range is in sparse upland spruce timber where snow cover is not excessively wind-packed and where forage is available. Some wind-blown alpine slopes also provide good forage. Other suitable winter range may consist mainly of sedges.

Several caribou herds range within the general area. The fortymile herd is in the White Mountains and Tanana Hills. The smaller Delta, Chisana, Mentasta and McKinley herds also range within the southern portions of the Tanana river drainage.

The grizzly bear of the Yukon Region, smaller than its coastal counterpart, tends to favor open slopes and mountainous areas. Black bears occur generally throughout forested valleys, preferring open mixed forests but also appearing on alpine tundra in their search for roots and berries. Dall sheep occur in the mountains of the Alaska Range to the south and east of the Tanana valley. Sheep occupy much of the alpine tundra in summer, but are restricted in winter to slopes blown clear of snow. Gray wolves and wolverines range throughout various habitats and may occur anywhere from the main river channels to high mountain ridges in either winter or summer, wherever their prey is available. Wood bison usually summer on the dry grass meadows on bars of the lower Delta and Gerstle rivers. Winter range includes pastures that do not become wind-packed; the animals move to windswept alpine meadows east of the Delta River in late winter and spring.

Much of the Yukon Region provides excellent habitat for diverse and abundant populations of terrestrial birds. Millions of migratory birds transit the North American continent and north Pacific Ocean in spring to breed and nest on lands drained by the Yukon River and its tributaries. About 28 species of resident birds remain in the region throughout the year.

The upper Yukon river basin is best known for the highly productive bird habitats in the streams, lakes, marshes and varied woodlands of the Yukon Flats. Twenty species of raptors birds occur in the Yukon basin and of these 18 breed there.

Bald eagles nest in small numbers along the river lowlands of the Yukon physiographic region, while a few golden eagles nest on ledges and other areas associated with alpine tundra. Ospreys, goshawks, red-tailed hawks and great horned owls are considerably more abundant than other large raptors and are widely distributed throughout forested habitats. The gyrfalcon is known to occur in the southern highlands of the area and may nest there.

The peregrine falcon is of particular importance because of its status as an endangered species and its relative abundance along the Yukon river. It may also nest on tributaries of the upper Yukon. Peregrines are diminishing in numbers; their lack of reproductive success appears due to the concentration of pesticide residues in their tissues. High pesticide levels have been found in Artic peregrine falcons within the eastern Yukon drainage and there is grave concern for the future of this population. Peregrine falcons nest on bluff faces too steep to support continuous vegetation or to provide access to the nest site by predators. A nest site may be utilized repeatedly, though it is common for a pair to utilize several sites over a period of years. Though the birds are very sensitive to human intrusion into the nesting area, traffic on major rivers does not seem to disrupt nesting activity.

Thirty-one species of shorebird, including plovers, sandpipers and phalaropes have been recorded along river or lake shorelines in this area. Recent work has shown that a migratory movement of 175,000 to 200,000 lesser sandhill cranes passes through the area of the upper Tanana river valley every spring and fall, making this one of the most significant avian migration patterns of the region.

More than 70 species of passerine birds utilize the habitats of the Yukon river region. Of these, at least four species appear to be restricted to the Tanana river drainage.

Despite long, cold winters, about 28 species of birds remain as winter residents. Included are two species of hawks, three of grouse, two of ptarmigan, four woodpecker species and about a dozen passerine species.

## Cultural Resources

This section deals with the archaeological and historical resources along the proposed routing of the Delta Junction oil pipeline alternative. The corridor extends along the Alaska Highway beginning at Delta Junction, terminating at the Alaska/Yukon border.

### Archaeological

Two of Alaska's most important archaeological sites, Healey Lake and Dixthada, are located near the proposed route between Delta Junction and the Alaska/Yukon border. Healey Lake, eligible for the National Register, contains the earliest radiocarbon-dated archaeological material uncovered in Alaska. The Dixthada site contains a long, almost continuous sequence connecting prehistoric and historic Athabascan culture of subsistence hunting.

Recent investigations are beginning to clarify the chronology and affiliation of early sites in the interior. The evidence from Healey Lake and artifacts discovered in association with non-extinct Pleistocene fauna along tributaries of the Tanana suggest that the area may be one of the most likely for discovery of Paleoindian sites. The lower part of the corridor crosses one the most favorable areas for continuous human occupation, which provides an ideal situation for information on developmental sequences. The orientation of historic and immediate prehistoric tribal units to major river arteries suggests that archaeological sites within the impacted corridor could reveal valuable information for ethno-archaeological studies which would expand our understanding of earlier economic and social systems.

A 1978 archaeological survey of the Alaska Natural Gas pipeline alignment from Delta Junction to the Yukon Border provided a 100 percent intensive walk-over coverage of all designated survey segments along the right-of-way. For the purposes of this survey, the criteria used to designate a site were: 1) a site exhibits definable limits; 2) it contains evidence of more than a single occurrence of human activity; and 3) if no other criteria exist for defining a site, then artifact density must be greater than five artifacts per square meter.

The walk-over survey found no sites within areas investigated. However, there are areas near the alignment where the configuration of topographic and other features suggests a camp location. Most of the human use of the area was found to consist of modern trails, traps and debris from building the Alaska Highway and the Haines and Canol pipelines.

### Historical

No historical sites are listed for this portion of the proposed pipeline route. However, the route would traverse the Forty Mile gold field region bordering Alaska and the Yukon and would parallel the Alaska Highway, built during the early years of World War II.

## Visual Resources

The proposed pipeline would lie in a transportation corridor which includes the Alaska Highway and the proposed Alaska Highway gas pipeline and the 8-inch Haines-Fairbanks pipeline.

## Land Use

In the region from the Yukon river south and east to the Canadian border, land uses are commonly the kinds associated with modern communities, transportation, and operation of federal facilities. Intermixed are subsistence and recreational uses of wild lands, some agriculture, and the commercial use of land along the highway system.

### Native Lands

There are four native villages, all lying within the responsibility of the Doyon Corporation and the Tanana Chiefs Conference, in the vicinity of the pipeline corridor. These are Dot Lake 1976 population - 63; Tanacross, 1976 population - 125, Tetlin, 1976 population - 112; and Northway, 1976 population - 215. The percentage of native residents of these four villages who continue to pursue subsistence activities only is about 3.5 percent. About 25 percent depend exclusively on wage employment, 27 percent on public assistance programs and the remaining 45 percent on both subsistence activities and wage employment.

### Wilderness Areas

All of the proposed oil pipeline route follows an established transporation corridor. No existing national parks, wildlife refuges, or wild and scenic river areas would be involved. Approximately 10 miles of the route near the Canadian border would be within the proposed Wrangell Mountains National Forest. No areas of potential wilderness would be involved.

### Agriculture and Forestry

Two small extensions of upland soil near Delta and Tanacross provide 70,000 acres of land suitable for cultivation. Some stands of white spruce and birch have commercial potential. There is a sawmill at Delta Junction and a small operation between Delta and Tok Junctions.

## Transporation and Utility Networks

The proposed Delta Junction to Keg River, Alberta oil pipeline would parallel the Alaska highway in Alaska. This corridor includes the 6-inch diameter Haines to Fairbanks military pipeline and three associated pump stations and would include the approved Alaska Highway Gas Pipeline and its operations and maintenance facilities.

### Airstrips

There are three federally owned, five state-owned, and five private airstrips between Delta Junction the Alaska-Yukon border.

### Highways

The Glenn highway from Anchorage terminates at the Alaska highway at Tok and the Richardson Highway joins the Alaska Highway at Delta Junction.

## Recreation Resources

Along the Alaska Highway from Delta Junction to the Alaska-Yukon border recreation activities such as hunting, fishing, boating, hiking, sightseeing, and cross-country skiing are extensive. There are seven state waysides for camping in this area: Gardiner Creek Campground, Deadman Lake Campground, Lakeview State Campground, Tok River State Wayside, Moon Lake Campground, Big Gerstle River State Wayside, and Clearwater State Campground. There are also about eight road-side picnic sites.

## Social and Economic Conditions

### Regional

The proposed project and all communities within 10 miles are included in the Southwest Fairbanks Census Division, which follows the Alaska Highway from west of Delta Junction to the Canadian border. The only settlement within the division whose population would be subject to direct or indirect impact from the project is Fort Greeley, a U.S. Army base. The division had a 1970 Census population of 4,189, of which nearly half were at Fort Greeley.

The population characteristics of the impact region (i.e., the Division excluding Fort Greeley) are summarized in table 9.5-1. The population is 20.7 percent Alaskan Native. Most of the Alaskan Native population lives in small villages and rural areas. The population of Delta Junction is mainly non-Alaskan Native. The sex ratio shows a slight preponderance of males. Most of the Delta Junction population is working age. There is a larger proportion of children and old people in the balance of the region.

The most recent population estimate for the Division by the Alaska Department of Labor was 4,893 in July, 1977. Average monthly wage and salary employment in the Division was 819 in 1977. The major industries of the region, excluding Fort Greeley, are trade services based on Alaska highway trade and local consumption demand. Other significant industries are state and federal government (state troopers, schools, FAA), seasonal construction, and transportation.

There are other important sources of "basic" income to the region, including income earned elsewhere on seasonal or occasional work such as major construction projects, transfer payments (native claims payment, disability, AFDC), subsidized services (health, schools), and in-kind value of the subsistence harvest.

Settlements

Settlements located on or within 10 miles of the pipeline route, pump stations, and storage facility as listed in table 9.5-2 are the ones most likely to experience direct or indirect population impacts. Further data on the larger settlements (25 or more) is given in table 9.5-3.

The four major native villages in the area are Northway, Tanacross, Tetlin and Dot Lake. A demographic survey of these villages was conducted in August, 1976 by University of Alaska researchers.

- 515 persons live in the villages, of whom 465 are native;
- 90.3 percent of the total village populations are Interior Alaskan Athabascan Indians;
- there is a potential workforce of 302 persons;
- 208 individuals have at least one job skill or area of work experience;
- 66 individuals or more have received formal vocational training; the training emphasis for males is construction-related, and for females is in clerical/office work;
- almost all native inhabitants are dependent to some extent on subsistence activities; only 24.8 percent are primarily dependent upon wage employment.

Community inventories show minimal capacity in the Alaska Native villages for serving the demands and service needs of a major non-native population influx. There are a cafe, bar, a state trooper station, and two general stores at Northway; a lodge (no bar, some groceries) at Dot Lake; clinics at Northway and Tanacross. There are no community water or sewer systems. It was noted that Northway is in fact two villages an FAA complex, mainly white, and 5 miles away a much larger village, mainly native.

TABLE 9.5-1 POPULATION CHARACTERISTICS OF DELTA JUNCTION SYSTEM

| | Delta Junction City | Rest of Division | Region Total 1/ |
|---|---|---|---|
| Total Population | 703 | 1,676 | 2,379 |
| White Male | 350 | 646 | 996 |
| White Female | 312 | 534 | 846 |
| Indian Male | 3 | 233 | 236 |
| Indian Female | 1 | 241 | 242 |
| Aleut Male | 0 | 2 | 2 |
| Aleut Female | 0 | 2 | 2 |
| Eskimo Male | 2 | 5 | 7 |
| Eskimo Female | 1 | 3 | 4 |
| Other Male | 17 | 4 | 21 |
| Other Female | 17 | 6 | 23 |
| Percent Native | 1.0 | 29.0 | 20.7 |
| Sex Ratio 2/ | 112.4 | 113.2 | 113.0 |
| Person 15 years and younger | 213 | 623 | 836 |
| Percentage | 30.3 | 37.6 | 35.4 |
| Persons 60 years and older | 9 | 116 | 125 |
| Percentage | 1.3 | 7.0 | 5.2 |
| Persons between 15 and 60 | 481 | 917 | 1,398 |
| Percentage | 68.4 | 55.4 | 59.2 |

1/ Native must enroll in a particular village, not necessarily current place of residence, to receive benefits under the Alaska Native Claims Settlement Act.

2/ Not an authorized native village for ANCSA purposes.

Community inventories show minimal capacity in the Alaska Native villages for serving the demands and service needs of a major non-native population influx. There are a cafe, bar, a state trooper station, and two general stores at Northway; a lodge (no bar, some groceries) at Dot Lake; clinics at Northway and Tanacross. There are no community water or sewer systems. It was noted that Northway is in fact two villages: an FAA complex, mainly white, and 5 miles away a much larger village, mainly native.

The other major settlements of non-native population are at Delta Junction and Tok. Community inventories are not presently available. Delta Junction, classified as a second-class city, and incorporated in 1960, is the only incorporated city in the region.

In this section, the environmental, social and economic elements described in the existing environment are analyzed for impacts of the Delta Junction system in both its preconstruction and construction and its operations and maintenance phases. Due to the conceptual nature of project design, no attempt is made to discuss ultimate abandonment of the system.

## Corridor Impacts

From Delta Junction to the Canadian border, the proposed alternative oil pipeline route would lie in parallel with that of the approved gas pipeline route and also in close association with the Alaska highway. At the present conceptual level of design, the term "corridor" can only be defined as a variable band of land, usually bounded by physiographic features, which would contain the highway and the two prospective pipelines within close proximity. Given that location constraints on various modes of transportation may vary, the alignments of the pipelines and the highway may diverge considerably in certain areas.

Disturbances during all phases would be confined to the corridor and would be incremental on those already existing there, i.e., there would be no new disturbance of wilderness or natural areas. The same logic would apply to water crossings where, for example, only one limited reach of a stream would be affected by the three transportation elements. All phases would also benefit from the easy access granted by the highway and the consequent reduction of disturbance from road-building activities. Surveillance, patrol, monitoring and response to contingencies would all be facilitated.

One of the few negative aspects of a corridor approach is the potential burden which could be placed upon the capacity of the atmosphere to disperse localized pollutants. This effect could be largely mitigated by locating pump stations some distance from compressor stations and by ensuring that neither are placed close to human settlements.

## Climate, Air Quality and Noise

### Construction Phase

No significant effects are perceived on macro- or microclimate during preconstruction and construction.

The impacts on existing air quality during these phases would generally be temporary. During the summer season, dust would be the primary particulate matter added to the air environment. Dust particle concentrations would tend to be greatest during the light-wind, somewhat inversion-prone night hours. These phases in winter would generate no significant amounts of dust but combustion products could develop higher concentrations than in summer. Construction camps or activity centers would briefly cause local concentrations of combustion by-products.

The equipment used in pipeline construction would increase noise levels. Additional temporary noise would be generated by explosives. Effects on wildlife would be temporary, and any adverse impacts could be minimized by proper construction scheduling.

### Operation Phase

No significant effects are expected to climate during operations.

In this phase, dust would be a minor concern. With respect to combustion products, winter time light winds and stronger, more persistent temperature inversions, coupled with topographic effects could bring about localized buildup of pollutants in the vicinity of pump stations. In winter, under calm conditions with ambient temperatures below -25°F, resulting in strong low-level inversions, ice-fogs may form in the vicinity of pump stations and may cause short delays in transportation in certain locales. These meteorological entities would be limited in a real extent and are of transient nature. Operations of the pipeline which might comprise potential ice-fog areas would be resolved on a site-specific basis.

## Topography and Geology

### Construction Phase

Within Alaska the pipeline route would require clearing, cutting and filling of up to 2,030 acres of terrain underlain by windblown silt, colluvium, alluvium, dune sand and exposed bedrock such as schist, limestone, and granite.

Large quantities of aggregate would be required as bedding for the pipeline in buried portions of the route.

In locations where the route would traverse steep slopes substantial cuts would be excavated, increasing the likelihood of downslope movement.

Geological Hazards. Within Alaska, Yukon Territory, and northwestern British Columbia the route would lie within seismic zone 3. Although major damage to structures can be expected due to earthquakes of Ritcher magnitude greater than 6 such an event is considered unlikely during the construction period.

### Operation Phase

Impacts to the pipeline, pump stations, and associated facilities would be expected from major earthquakes and downslope movements. In places where the route crosses thick deposits of alluvial, colluvial, or aeolian material, particularly where water-saturated, ground shaking, differential settlement, liquefaction, or slump could damage or rupture the pipeline during a severe earthquake. On steep slopes, rockslides, rockfall, slump, or landslides may also damage facilities; in some cases the likelihood of downslope movements may be increased by excavation.

## Aquatic Resources

### Construction Phase

Construction would introduce added sediment into waterbodies. No permanent alteration of stream hydraulics or impediments to fish migration would occur.

There would be localized utilization of supplies of water for hydrostatic testing and, during discharge of the testing liquids, some alteration in the temperature regime and in the channel morphology of the receiving streams.

### Operation Phase

There is a remote possibility of pipeline rupture and oil spill into aquatic systems. The extent would be limited by block and check valves and leak detectors.

## Terrestrial Vegetation

### Construction Phase

The following impact discussion was adopted from the Federal Power Commission's FEIS on the Alaska Natural Gas Transportation Systems (Vol. II issued April 1976 and supplement issued September 1976), and the USDI, Bureau of Land Management's FEIS issued March 1976.

Vegetation would be cleared from the proposed route, access roads, work camp areas, compressor station sites, graded slopes, and gravel pits. The direct impact of clearing would be minor compared to total vegetation throughout Alaska. Local and indirect impacts on vegetation and animal species would occur as a result of clearing and would be more critical.

Removal of the insulating plant cover and exposure of bare soil along the pipeline route would induce local changes in the microclimate and initiate a series of impacts on the soil leading to soil instability and erosion.

In permafrost areas, clearing of vegetation and compression of the organic mat by construction equipment would allow increases in soil temperatures and increase the depth of thaw along the proposed route during the summer, causing some degradation of the upper layers of permafrost, perhaps triggering a host of phenomena such as subsidence and slumping. Such soil instability would encourage erosion and weaken the support of existing vegetation. Conversely, the increased depth of thaw and increased soil temperatures would encourage root growth, change the amount and distribution of soil moisture, and slightly lengthen the growing season. This would aid revegetation, although the species that would benefit most from permafrost degradation might not be the species originally occupying the proposed route.

Lower soil moisture in the pipeline berm, and increased micro-relief, would create another set of conditions alien to the present plant communities and would probably result in at least two new sets of communities growing along the crest side slope of the pipeline mound. These changes in plant species occurrence and communities would radically modify the landscape through which the pipe passes and make its location easily visible to the knowledgeable observer.

Soil compression, permafrost degradation, berm left atop the pipeline trench, trenching, erosion control measures, grading, and gravel pad construction could alter existing drainage patterns on the surface or beneath the soil. Compression would hinder moisture penetration and decrease the moisture retention of the soil. Berms would tend to create moist spots uphill from the trench while making areas downhill drier. Berms would also intercept drifts of windblown snow and create slower-thawing spots in the spring. Subsurface drainages might be intercepted by the pipeline trench and channeled away from their original directions of flow. Erosion control measures required where the vegetation would be cleared would create new runoff patterns. Grading would alter slopes and reduce topographic irregularities, altering runoff and moisture penetration. Gravel pads would block surface drainages and compress underlying soils to some extent. Culverts installed in gravel pads would redirect surface flows.

Whatever the mechanism behind a change in drainage pattern, some change in the distribution and type of vegetation along the right-of-way would result. Where water is impounded, vegetation will be drowned and eventually the present plant communities will be replaced by pond, marsh, and wetland vegetation.

Vegetation downslope which is deprived of its normal water supply would be replaced gradually as plant species better adapted to drier sites became established. The downslope changes may be slower than the upslope changes, but the ultimate results would be the same--i.e., replacement of the present natural vegetation by a new mosaic of communities.

Some merchantable quality forest would be cut in crossing the bottomland and spruce-hardwood and upland spruce-hardwood type. A closed forest canopy does not exist and timber stands of merchantable quality and quantity are widely scattered. The amount of timber to be removed within the immediate impact zone would be insignificant. This timber, although economically marginal, should be salvaged where possible. Since only a small timber area would be affected and possibly salvaged, the impact on commercial forest is considered insignificant. Local stands would have value to nearby users and could be salvaged for local use.

Along most of the proposed pipeline route, the topsoil on which vegetation depends is relatively thin. The excavation of the pipeline trench would expose less fertile subsoils. If care is not taken to assure that the topsoil is replaced atop the berm when the trench is filled, the trenched area would lose fertility and probably would not revegetate as quickly, nor with the same species, as the rest of the right-of-way.

Wherever land is cleared, adjacent vegetation would be exposed to the wind and would be more susceptible to wind damage.

Vegetation killed or weakened by construction activities and numerous indirect impacts would provide breeding grounds for insects and disease organisms, particularly if the vegetation cleared from the route were not quickly and properly disposed of. The spruce bark beetle, for instance, could breed in dead vegetation, then attack living white spruce trees. Vegetation injured during the construction process or weakened by exposure of its roots, loss of soil moisture, or contact with toxic chemicals would be more susceptible to invasion by insects, fungi and plant diseases. Vegetation already infected would suffer greater impact from parasites because of construction-related stresses.

As noted in the discussion on permafrost degradation, clearing of vegetation would expose more of the ground surface to sunlight. Besides increasing the soil temperature, this exposure would affect vegetation adjacent to the cleared areas and influence revegetation. Shade-intolerant species near the clearings would proliferate, while species requiring shade would be eliminated, at least temporarily.

Surface vehicle travel during the winter causes much less disturbance of the tundra soils and vegetation than at other times of the year. But even in the winter, varying amounts of damage will occur. The extent of damage will depend on the depth of snow cover, microrelief of the site, vegetation type involved, amount of soil moisture, and depth of organic layer.

Secondary impacts resulting from construction and operation of the pipeline would affect an additional but undetermined area through changes in the plants' environment. These secondary impacts, which modify habitats, would result in greater long-term changes in plant communities and the functioning of tundra and boreal forest ecosystems than the seemingly more severe short-term construction impacts.

### Operation Phase

Following construction, the entire right-of-way would likely be reseeded with exotic grass and herb species. Evidence to date indicates that certain exotic varieties of grasses can be expected to germinate and grow more successfully than the native grasses tested, at least during the first 2 or 3 years. The native grasses will gradually dominate the site as the percentage of plant cover increases, but plant succession proceeds very slowly in the Arctic and it could be 50 years or more before the vegetation on the pipeline mound resembles that in the adjacent undisturbed communities.

Of the 90-foot right-of-way needed for construction, 75 feet would be retained as a permanent right-of-way. During the life of the proposed project some means of shrub control would be needed. The removal of shrubs would prevent normal succession and maintain the vegetation at a lower successional stage. Manual maintenance clearing would produce impacts similar to but less extensive than those produced during the original clearing. Maintenance vehicle movements would add to soil compression along the route. Herbicides might also be employed in some areas along the right-of-way to control vegetation. Used indiscriminately, herbicides could be carried off the right-of-way by wind and water to impact vegetation some distance from the area of intended control.

Emergencies would require pipeline repairs during the summer when the ground is not completely frozen. It is during the period when the root zone is thawed that all plant communities are most susceptible to disturbance, and repair and maintenance activities at that time have the greatest potential for adverse impacts on tundra vegetation.

Low shrub-heath vegetation is less severely damaged by summer vehicle traffic but, as with other vegetation types, the degree of disturbance depends on vehicle weight (and ground pressure), track design, soil moisture, proximity of frost to ground surface, and the number of vehicle passes across the surface.

The potential of pipeline or equipment failure must also be considered a potential threat to increasing the risk of forest fires.

Most toxic spills associated with the operation of the proposed pipeline would probably occur in the vicinity of the compressor stations and in other areas where supplies and equipment were stored. Maintenance and repair activities along the route might also lead to spills. Oil spills due to a slow leak or a major break could significantly impact the environment.

### Abandonment Phase

Abandonment of the pipeline will likely mean filling it with an inert material and leaving it in place. Under these conditions, no further impacts to vegetation would occur.

Impacts associated with revegetation will remain until such time that native species have reestablished on the site.

### Ecological Reserves

Two proposed reserve units could be impacted by the construction and operation of a pipeline system throught the Tanana river valley.

The Healy Lake and River which is located 30 miles east of Delta Junction is approximately 10 miles from the proposed pieline corridor at its closest point. It is unlikely that any activities of the pipeline construction would impact the reserve. However, operation of the pipeline entails the risk of oil spills, and should one occur at the Johnson River crossing, the oil would enter the Tanana River and flow toward the Healy Lake area. Depending on the size of the spill, how soon it is detected, and how quick clean-up operations began, impact to the reserve unit could be severe. For a discussion of oil spill impacts on aquatic systems see chapter 3.

The Robertson River is located 20 miles northwest of Tanacross, and would be crossed by the pipeline. A bridge exists across the river for the Alaska Highway, and could carry the pipeline; however, no such proposal has been mentioned. Whether the pipeline is carried by the bridge, buried under the river, or crosses the river above ground at a location other than at the bridge, impacts to the river would occur during construction. The severity of these impacts would depend on the type of river crossing. The potential for impacts also exists during the operation phase due to the risk of oil spills. An oil spill at the Robertson River crossing would potentially affect 2 miles of the system downriver from the crossing. Most of the impact would be felt in this area, but the effects would also show up in Tanana River.

## Terrestrial Wildlife

### Construction Phase

For the most part, construction of a warm-oil pipeline along a route wherein a certain degree of industrial activity has already occurred would be a continuation of existing stresses or an increment to them. Movements of people, trucks, heavy equipment, aircraft and similar activities would already have had their effect, animals intolerant of such disturbance may have already moved away or otherwise adapted. Disturbances such as blasting could disrupt nesting of birds and animal migrations, but such damage could be reduced by careful scheduling.

Raptors nesting on bluffs over the Tanana River and concentrations of nesting birds near lakes east of Northway would be of major concern with respect to blasting activities. Such activities should not have significant effects on mammals. General construction activities and noise could disturb peregrine falcons and Dall Sheep during nesting and lambing periods.

### Operation Phase

Pump station noise could deny some species the use of certain areas of habitat. Again, raptor nesting habitat along the Tanana River heights would be an area of concern. There is some latitude for adjustment of the locations of pump stations along the pipeline route, which would give scope for avoidance of critical habitat.

The above-ground section of pipeline could form a barrier to caribou from the Fortymile, Mentasta, Chisana and Delta herds. Small numbers of bison might also be affected.

## Cultural Resources

### Construction Phase

The impact associated with the proposed construction could be both direct and indirect. Direct impact would result from actual pipeline construction activities such as digging for gravel and riprap, landclearing, ditching and levelling of land by blasting, ripping, and blading. Where such activities do encounter sites these would be either partially of totally destroyed. Indirect impact would occur if workers collected artifacts for souvenirs or where soil erosion, soil creep, and other secondary disturbances affected physical and chemical integrity of the sites.

A 1978 surface survey of the proposed alignment found no evidence of "sites," therefore such impacts are unlikely along the pipeline corridor.

While no prehistoric or early historic period sites are present within the proposed alignment, there are areas nearby where the configuration of topographic and other features suggests a camp location. Access routes could have an adverse impact on these.

The 1978 surface survey found no indication of sites along the proposed right-of-way; however, there is potential information to be derived from the distribution of isolated artifact clusters which were considered as "non-sites." Such phenomena are to be recorded and located on maps whenever encountered in further studies.

As with archaeological sites, the impact of pipeline construction on historical properties would relate directly to location of construction activities and mitigative measures adopted. Construction activity and/or the siting of compressor stations or maintenance yards could permanently alter the environment around historical sites.

However, no historical sites have been identified to date along the proposed right-of-way.

### Operation Phase

There would not likely be any impact on cultural, archaeological, or other unique features during the operations and maintenance of the pipeline.

Immediate indirect or secondary impact would come from souvenir collecting and/or vandalism, which could remove scattered trail side artifacts or archaeological value.

## Visual Resources

### Construction Phase

Clearing of a pipeline right-of-way requires removal of existing vegetation and exposure of the soil which results in an immediate visual impact. Where a swath must be made through forested areas revegetation will result in a moderate color and texture contrast. Where the pipeline is designed to be above ground the installation of pipe supports would affect the aesthetic quality of the local environment. Since the route of the proposed alternative would lie in an existing transportation corridor where significant visual impacts have already occurred, the contrasts would be minimized.

### Operation Phase

The above ground pipeline would affect the aesthetic quality of the corridor as would the visibility of the pump stations located in the corridor and the storage facility at Delta Junction. The development of new borrow pits could also contribute to reduction in scenic qualities along the highway. Much of the granular material required would be taken from existing pits thus minimizing the opening of new pits and reducing the possibilities for further aesthetic degradation.

## Land Use

### Construction Phase

The major possible impacts upon existing land uses during the construction phase would relate to the physical condition of the Alaska Highway and road system; the usual uses of that road system (for commercial and recreation purposes); airports and airfields; grave material sites; and the general utilization of lands for recreational and subsistence hunting, fishing and trapping purposes. Such impacts must be assessed in light of the fact that construction would be along a route where industrial activity has already occurred. These impacts would be continuation of existing stresses or an increment to them. Movements of people, trucks, heavy equipment and aircraft, would already have had an effect, and wildlife, intolerant of such disturbances may already have moved away or otherwise adapted.

Although appropriate measures would be taken to reduce adverse effects, some localized and short-term noise and dust disturbance to residences and communities could be anticipated, where project construction or movements of manpower and materials occur in close proximity to local populations. The impact upon agriculture or forest products would be negligible.

Gravel would be required and the need for borrow pits would result in short-term impacts to the environment. In some cases revegetation after construction could be used to prevent potential long-term impacts. Some gravel sites would have to be left open.

Both short and relatively long-range impacts would be expected upon subsistence and recreational activities involving fish and wildlife resources along the proposed route.

Disposal of waste materials consisting of spoils, vegetation (including trees), construction materials, camp wastes and hydrostatic test water would impact upon various land uses.

Operation Phase

Upon completion of construction, impacts on the physical conditions of the Alaska Highway and road system, existing recreational and commercial uses of the system, airports, water supplies, material sites and utilization of wildlife should, for the most part, be eliminated. High volume heavy traffic should no longer be a problem nor should competition with existing uses. There should no longer be a load on any port facilities, railroads or airports that would be used to transport construction materials.

Certain material sites would be required for operation and maintenance of access roads, pump stations, airstrips and other appurtenances of the line. At these sites, revegetation and rehabilitation would be delayed as long as materials were needed.

Utilization of lands would be reduced when large numbers of construction personnel are no longer required.

The demands on water supplies would be to meet the need of small crews at pump stations, with the exception of water requirements for hydrostatic testing in the event of pipe failure and repair.

Both requirements would be significantly less than those for construction camps and hydrostatic testing during construction.

Solid wastes would accumulate during operation in much smaller quantities than during construction. Disposal of wastes requires care in site selection to avoid thermal degradation of soil or contamination of ground water supplies. Proper storage and frequent disposal of all wastes, usually by incineration, would avoid the continuing problems associated with scavenging animals.

## Transporation and Utility Networks

Construction Phase

The material supply transportation system to support construction of the Delta Junction alternative would utilize existing facilities and infrastructure. Materials for the construction of the Alaska segment would be delivered through the ports of Anchorage and Valdez and moved to the existing right-of-way via existing surface transportation networks (the Alaska Railway and Alaska State Highways, Numbers 1, 3 and 4) which connect the port facilities with the Alaska Highway, located adjacent to the pipeline right-of-way. Materials for the Yukon segment would be brought into the ports at Haines and Skagway and moved via the Haines and Skagway-Carcross Highways and the White Pass and Yukon Route railway. A relatively minimal amount of land preparation would be required at Skagway and Haines for storage. Although the existing infrastructure and supply networks are considered capable of accommodating the projected traffic volumes, the increased traffic levels, caused by workers, construction activity, and shipping of project pipe and supplies, would create some impacts. Congestion could occur in the vicinity of Delta Junction and Tok and to a lesser extent at the customs station at the border.

An area of major highway impact would be that segment of the Alaska Highway from the Tanana River east of Tok to the Canadian border. This section of road was built with marginal materials and designed for low-volume traffic.

During Alyeska's pipeline construction, the many airstrips along the route were generally able to absorb the impact. The airports along the Alaska highway could be expected to handle this project's demands as well.

Operation Phase

During the operation phase, transporation impacts should be minimal.

## Recreation

Construction Phase

Increases in traffic and uses of campgrounds along the Alaska Highway during construction could overtax the capacity of the existing campgrounds in the pipeline corridor.

Experience on other projects of a similar nature in the western provinces of Canada and with the Alyeska project indicates that a percentage of the work force would be visited by relatives while at the worksite. The low cost of campgrounds and close proximity to work areas would likely attract a number of visitors during the summer months. The number of campground users would be augmented by other project induced in-migrants who arrive with camper units. With no expansion of existing facilities any additional demands for campground space would result in campsites reaching capacity early in the season and with shortages perhaps occurring during peak periods in July and August. Congestion at campgrounds could create some inconvenience for tourists and recreationists. If congestion occurs in campgrounds it could lead to increased camping in unserviced areas, which could create problems such as improper garbage disposal.

The construction of the pipeline near campgrounds may cut off access for short periods of time. Campers in campground sites near construction activities could experience noise and dust associated with the large work force and the movement and operation of heavy machinery.

Operation Phase

During operation the pump stations would be located far enough from campgrounds to preclude disruption of campground activities.

## Social and Economic Conditions

Employment

Direct employment on the project would be of local and Alaskan residents as much as possible, but a large number of non-local and out-of-state workers would still be required. Local consumption and expenditures of non-local project workers during construction would be minimized by company policies of siting and servicing the construction camps away from existing villages but could still leave a significant temporary impact. Trade, service, and government employment growth could be expected throughout the region, especially affecting the settlements already having significant highway-oriented commercial facilites (Tok, Delta Junction, Border City). Major Alaskan cities, especially Fairbanks, would also get some trade. Operating employees would be free to locate in existing communities and would contribute to longer-term growth. Abandonment of the project would cause some local unemployment.

Incomes

Experience of other remote pipeline projects suggests that over half the construction wages would be sent out of the region, but a large part of the operating wages would be spent there. Both the construction and operation phase payrolls would be significant in the economy of the region.

Population

The total population influx is estimated to include 15 dependents for every 100 construction jobs, and 130 dependents for every 100 induced or operating job. A number of speculative job seekers could be expected for short periods because of easy highway access. The total influx to construction camps and existing settlements could be considerably larger than the present population of that region. At the beginning of operation, the population would drop, but existing settlements would grow as they absorbed operation workers, their dependents, and other persons induced to move into the project area.

Housing

Existing settlements have negligible permanent housing capacity relative to the size of the expected influx. Approximately 150 housing units would be needed by the operating and induced work force and dependents. In addition, the provision of serviced camper space would discourage the formation of squatter camps with associated water pollution, fire and health hazards.

Community Services

New community or household water and waste systems would be needed. Major expansions of other services would be required commensurate with the population impacts.

The Delta Junction local government would bear short-term expansion costs but be rewarded with a large increase in its property tax base.

The cost of state services would rise commensurately with permanent population, but should be more than compensated with increased income taxes and royalty netbacks.

## CANADIAN ROUTE ANALYSIS

The following analysis concerns the alternate pipeline route which continues on from the Alaska-Yukon border. The Canadian portion described here extends from the Alaska-Yukon border near Beaver Creek to Squanga Lake, Yukon.

As would be the case in Alaska, the pipeline route in Canada would closely parallel the Alaska Highway gas pipeline route which in turn follows the Alaska Highway corridor from the Alaska-Yukon border to the vicinity of Squanga Lake. The oil pipeline would thus be located within an existing transporation corridor already occupied by the Alaska Highway, the Alaska Highway Gas Pipeline, the Haines-Fairbanks products pipeline (from border to Haines Junction), several communities (e.g., Beaver Creek, Burwash Landing, Haines Junction, Whitehorse) and associated infrastructure. Prominent natural features along the route include the Pickhandle Lakes complex, the Kluane Range of mountains and Kluane Lake, the Ibex Pass-Mount Ingram area near Whitehorse, the Yukon River, Marsh Lake and Squanga Lake.

### Terrestrial Vegetation

A pipeline project necessitates clearing of land for the pipeline right-of-way and for permanent and temporary facilities. Vegetation would be removed from these areas and thus the impact is localized. On areas disturbed by the pipeline project revegetation would follow. At certain permanent facilities such as pumping stations, vegetation would be eliminated over the long term. In summary, impacts on vegetation would be localized, but unavoidable. Rare or unique communities or complexes would be protected as much as practical.

### Terrestrial Wildlife

The project would result in some level of short-term disturbance to terrestrial wildlife and in localized loss of habitat. Both mammals and birds would be affected.

### Hydrology and Water Quality

During the preconstruction-construction phase of a pipeline project, potential impacts on hydrologic resources would usually arise from activities such as negotiating water crossings and withdrawing water for project purposes, or by drainage interruption and from pollution sources such as camp wastes and fuels, lubricants and chemicals.

During operation, the above applies to a much lesser extent; however, in the case of an oil pipeline, greater concern relates to a potential pipe failure, resulting in the release of oil into the environment. The ultimate concern is for water quality in the context of domestic and recreational use, aesthetics, and aquatic habitat for fish and wildlife.

Serious impacts on hydrologic resources are not anticipated. Sources of potential hydrologic impact would be addressed in depth during detailed project planning. Particular emphasis would be given to appropriate design (e.g., block and check valves, and leak detection system) and location of the pipeline to limit potential impact of any pipe failure and to contingency planning for response to pipe failure.

Fishery

Over 25 species of fish inhabit the major drainage systems crossed by the pipeline route, but not all these are found in the immediate vicinity of the route. Included among the species found along the route are chinook and chum salmon, arctic grayling, and several species of whitefish. Potential impact on fish resources relates primarily to habitat alteration, particularly through siltation, and secondarily through introduction of other harmful substances, water withdrawal or level change, and physical disruption of important sites (e.g., spawning beds).

Land Use

A pipeline project necessitates a commitment of land for project facilities, thereby excluding other possible uses of the land. This principle is compatible with the concept of a multiple use corridor. Current land use patterns along the Alaska Highway corridor from the Alaska-Yukon border to Squanga Lake result in a scattered patchwork of land committed to human use. "Developed lands" are primarily associated with the highway, highway facilities (campgrounds, service stations, etc.) and townsites. Other committed lands include Kluane National Park, the boundary of which parallels the Alaska Highway. Some of the lands in the corridor are also used for less concentrated activity such as recreation, trapping, hunting and fishing.

Implications of the Canadian Corridor

The Canadian segment of the Delta Junction alternative pipeline route runs from the Alaska/Yukon boundary near Beaver Creek to Keg River, Alberta. This is a distance of 934 miles, of which 727 miles (or approximately 78 percent) lies within a "transportation corridor." This corridor would contain three elements, the Alaska Highway, the approved gas pipeline, and the prospective oil line.

## 9.6 Alternatives of Kitimat Pipe Line Ltd. Proposal

### ALTERNATIVE PORTS AND ROUTES

Four alternative ports and routes to move crude oil via pipeline from the West Coast of British Columbia to Edmonton were identified for consideration in the preliminary stages of the project. The Bella Coola alternative, the Ridley Island alternative and the Port Simpson alternative were all rejected due to adverse marine conditions (Kitimat Pipe Line, Ltd. 1976).

The fourth alternative, the Kitimat alternative, was selected as the most feasible and practical port-pipeline system. Investigations of environmental and socio-economic feasibility were focused on this proposed port and route.

Following Kitimat's submission to the Canadian National Energy Board, supplemental information was requested (Kitimat Pipeline, Ltd. April 1977). The Canadian NEB submitted the following to Kitimat Pipe Line, Ltd.:

> The submission describes a number of alternate port sites on the northern coast of British Columbia and gives some reasons why they were considered less suitable than Kitimat. Since the objective of the project overall is to provide a transportation terminus for oil bound for the north central United States, it is not obvious that the northern coast of British Columbia is the only possible port location. In addition, a detailed comparative base must be developed and described to clearly show the relative values of alternative sites. Included in such a study must be evaluation of alternative sites. Included in such a study must be evaluation of alternative approach routes which are in fact simply an extension of the sites themselves.
>
> For all alternative port sites, provide order of magnitude cost estimates, including system capital costs and throughput costs per barrel, as a comparision of the economic advantages of selecting Kitimat as the port location.
>
> For all alternative port sites, provide a comparative analysis of the risk of oil spill accidents which would arise from the operation of each of the alternatives.
>
> Provide an examination and comparison of alternate marine approach routes to Kitimat. Factors to be discussed should include navigational feasibility, environmental implications and relative probability of accidents which would result in damage to the environment."

Kitimat Pipe Line, Ltd. submitted Volume VII, supplemental information, on April 12, 1977, to the Canadian NEB.

Kitimat Pipe Line, Ltd's response to the Canadian NEB's question regarding alternatives was as follows:

> The proponent has selected Kitimat as the site for its proposed marine terminal for the reasons set forth under the tab "Site Selection" in Volume I of its TERMPOL Submission and in Section IVA of Volume I of its Application to the National Energy Board. The selection was based on a comparative

analysis of navigational and environmental considerations and distance factors.

The proposed marine terminal at Kitimat is an integral part of the pipeline system designed to transport oil from Kitimat to Edmonton which is the subject of a specific application by Kitimat Pipe Line Ltd. to the National Energy Board for a Certificate of Public Convenience and Necessity. The Application will be subject of a public hearing to be heard during the summer. The same Project will also be one of the subjects of the public inquiry to be conducted by Dr. Andrew Thompson. The proponent is committed to the pipeline route from Kitimat to Edmonton and to Kitimat as the location for the marine terminal. Under these circumstances it is submitted that the provision of cost estimates and comparative analyses of the risk of oil spill accidents for alternative port sites would not serve any useful purpose. The proponent is not prepared to propose or undertake a Project different from the one described in its Application to the National Energy Board and its TERMPOL Submission. It is therefore not prepared at this time to commission further studies relating to alternative port sites.

This information was submitted as part of the Kitimat Pipe Line, Ltd. application under Title V of the Public Utilities Regulatory Policies Act on December 5, 1978.

Cherry Point

Bureau of Land Management

## 9.7 Alternatives of Trans Mountain Oil Pipe Line Corporation Proposal

### PORT AND ONSHORE FACILITIES ALTERNATIVES

### CHERRY POINT

Cherry Point is located at the south end of the Strait of Georgia, approximately 10 miles from the Canadian border and 140 miles from the Pacific Ocean (figure 9.7-1). There are two oil refineries, Atlantic Richfield Oil Company (ARCO) and Mobil Oil Company at Cherry Point. The companies have berthing facilities located in 65-foot and 42-foot water depths. Cherry Point is currently served by tankers.

Trans Mountain's Cherry Point alternative includes a new dock immediately north of the existing facilities with two berths, each capable of accommodating up to 200,000 dead weight ton tankers. This alternative also includes an onshore storage facility consisting of eight 500,000 barrel tanks, and a new 30-inch pipeline approximately 28 miles long from Cherry Point to Sumas at the International Boundary. (The alternate pipeline segment is about 15 miles long from Cherry Point to its juncture with the prime route near Laurel. From the International Boundary the new 30-inch pipeline would continue to Edmonton, Alberta.) At Cherry Point a new 12,000 horsepower pump station would be installed.

Construction of this proposal is prevented by amendment to the Marine Mammal Protection Act (PL 95-136).

#### Climate

The general climate of western Washington discussed in Chapter 8 in the section on Meteorological characteristics at Bellingham (located about 12 miles east-southeast of Cherry Point) and Blaine (located about 8 miles north) is considered representative of Cherry Point.

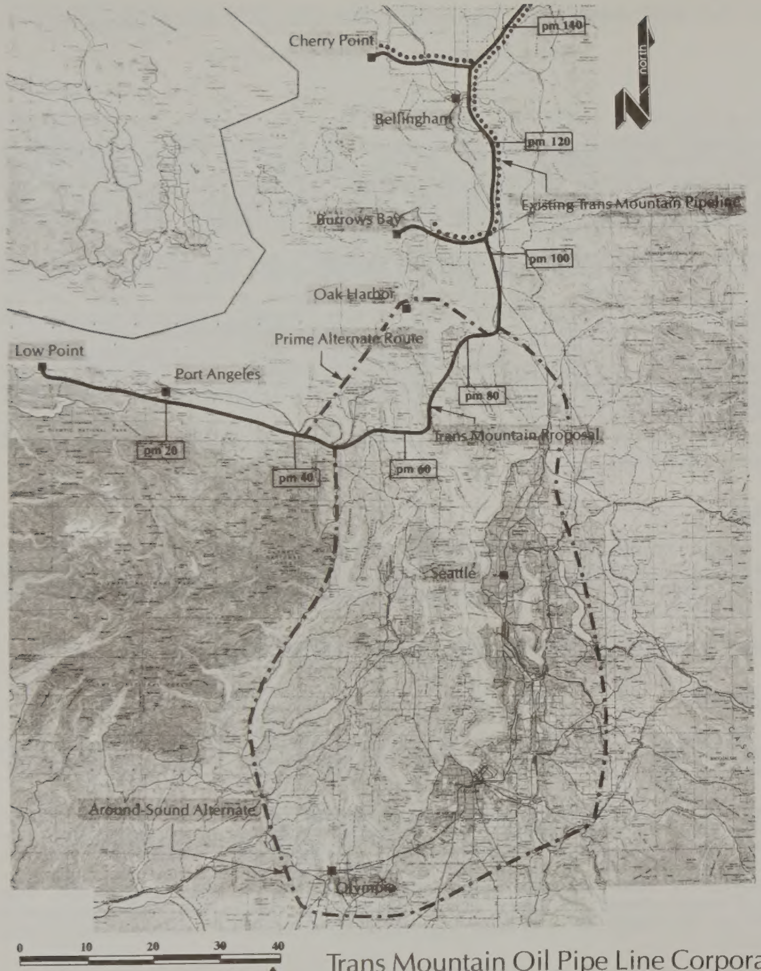
No impacts on climate are anticipated for this alternative port site.

#### Air Quality

The proposed alternate port would be located within the Northwest Air Pollution Authority (NWAPA) Control Region, which includes Island, Skagit, San Juan, and Whatcom Counties.

Construction activities associated with both the tank farm and pipeline would be expected to generate small quantities of air pollutants, primarily dust from excavations and suspended particulates from the exhausts of construction vehicles and workers' automobiles. Construction of the berthing facility would generate quantities of stack gas from construction-related tug activity and exhaust from pile drivers. Except for local areas within the construction sites these pollutants would not be likely to contribute significantly to existing concentrations in the vicinity.

During the operation phase, emissions from the port and onshore storage facilities would be about the same as those for the primary site. No modeling analysis has



Trans Mountain Oil Pipe Line Corporation

Port and Route Alternatives

Figure 9.7-1

been performed for the Cherry Point site. Therefore, no definite assesssment of air quality impacts could be made.

## Topography and Geology

The topography at the onshore storage facility site is fairly level. The topography from Cherry Point to the primary route near Laurel consists of gently rolling uplands and the relatively smooth lowlands of the Nooksack River Valley. Elevations range up to about 260 feet above sea level. Construction of the alternative route would result in relatively minor landscape changes.

Geologic materials at the site of the onshore storage facilities consist of glacial-marine deposits of unsorted, unstratified sandy silt and pebbly clay. The alternate pipeline route would cross glacial-marine, glacial drift, and alluvial deposits on relatively gentle terrain. Potential slope instability problems are identified at about pipeline mile 18. Other slope instability problems possibly exist along the route. No significant geological impacts are expected from construction of this alternate.

The proposed alternate port and pipeline route to the Canadian border are located in an area of moderate to high seismic activity that has been classified as a Seismic Risk Zone 3 (maximum earthquake damage expected). However, no known active surface faults have been identified along the route and only a few significant earthquakes (Modified Mercalli Intensity V or greater) have occurred with epicenters within 10 miles of the proposed facilities. Liquefaction of saturated sands in the Nooksack River Valley is possible, with resultant impacts similar to those described for the proposed route.

## Soils

The onshore storage facilities would be located on soils of the Cagey-Norma association consisting of mainly silty clay loam to loam. These soils occur eastward along the alternate pipeline route toward Ferndale, along with Whatcom, Lynden, and Kickerville soils which include some gravelly to sandy loam. Crossings of the Nooksack River Valley are dominated by Puget soils of silt loam and fine sandy loam texture. The uplands from Ferndale to the Canadian border are comprised mainly of Whatcom and McKenna soils with silt-loam texture.

Impacts to the soils from construction of these alternate facilities would be similar to those described for the proposal. These include disturbance of topsoil; destruction of soil profile along the excavated pipeline trench and at the site of the storage tanks; soil loss through water erosion; minor to negligible loss from wind erosion; and loss of soil productivity. Impacts would be minor and for the most part temporary.

## Aquatic Resources

### Physical Components

No major streams exist at the proposed alternate port and storage facilities.

The proposed alternate pipeline route crosses the Nooksack River northwest of Bellingham and several small streams. The Nooksack River in this area is designated Class A (at the primary route crossing, it is designated Class AA).

Ground water is present along the proposed pipeline route from Cherry Point to the upland areas west of Ferndale, and is contained in glaciofluvial and alluvial deposits. This resource has been developed for domestic, industrial, and municipal use. Recharge by precipitation is in considerable excess of well withdrawal. Ground water in this area is generally excellent. The water is usually low in dissolved solids, although high concentrations of iron do occur in some places. Impacts to surface and ground water during construction, operation, and abandonment of the pipeline are similar to those described for the proposed route. This alternative would cause the least impacts on water resources since approximately 10 stream crossings would occur along this alternative compared with approximately 43 for the proposed route.

### Biological Components

Impacts on fisheries resources for this alternative would be the same as those discussed for the proposed route but would be less damaging since approximately 10 stream crossings would occur compared with 43 along the proposed route.

## Marine Resources

### Physical Components

Currents at Cherry Point are controlled by at least four major factors: 1) tides, 2) meteorological conditions, 3) bottom and shoreline topography, and 4) runoff from the Fraser River. A general counter-clockwise flow of water exists within the southern Strait of Georgia. Approximately every 24 hours there are two high and two low tides. Maximum wave height in the Bellingham area may reach 5.5 feet between October and May (Oceanographic Institute of Washington, 1974). Areas in all parts of the San Juan Islands not exposed to waves from the Strait of Juan de Fuca have maximum wave heights of less than 4 feet. Exposed areas may experience waves and swells of the size prevailing in the Strait. Wave heights are less than 2 feet in the Bellingham-San Juan Islands region (Oceanographic Institute of Washington 1974). Cherry Point's location on the inner north Puget Sound provides a relatively mild wind and wave environment.

Marine water in this area generally consists of seawater flowing into the Strait at depth and less saline surface water from river discharge flowing seaward. Marine water in the southern Strait of Georgia has been designated extraordinary (Class AA). Marine waters in Bellingham Bay, Samish Bay, and Dilla Bay are affected by domestic and industrial waste discharges. These marine waters are considered excellent (Class A).

Impacts on marine water quality would occur during construction of the port. Construction of the offshore unloading facilities would suspend bottom sediments and temporarily degrade water quality. A major oil spill from a tanker or unloading pipeline would degrade marine water quality.

### Oil Spill Risk Analysis

Vessel transit distance from Buoy J to Cherry Point is 126 nautical miles. The risk of an oil spill from an in-transit tanker is expected to be one spill every 2.8 years. The probable size distribution of these spills is shown in chapter 8. The frequency of fire for in-transit tankers is 71.9 years. The frequency for explosions on in-transit tankers is 68.4 years. Bunker barge oil spill frequency for spills greater than 2.4 barrels but less than 10 barrels, is estimated as once every 4.65 years for 205 port calls per year and once every 2.34 years for 407 port calls per year. Oil spill frequency for the onshore storage facility, spills greater than 2.4 barrels but less than 10 barrels, could occur every 2.94 years. Fire and explosion frequency for the onshore storage facility, for damages greater than $1,000 but less than $10,000, is once every 62 years. The annual risk of a spill along the pipeline segment is one spill every 13.77 years (TMC 1979).

Trajectories for hypothetical in-transit or at-berth oil spills in March and September are shown in Map Addendum. Because the Cherry Point spill site is very close to the northern limits of the tidal current and wind mode boundaries, the results are approximate. During March conditions the most probable impact area is the coast along Cherry Point. Southerly transport is possible due to frequent inland high pressure systems during this time. Under these conditions Orcas Island, Sucia Island and Matia Island would be threatened. An oil spill in September would tend to travel rapidly to the northwest and into Canadian waters. If the spills that travel into Canadian water do not beach, there is the possiblilty that they would be entrained in the Fraser River runoff and be transported back into the spill area. Table 9.7-1 gives the shoreline of the most likely initial oil impacts.

TABLE 9.7-1 MOST LIKELY REGION OF FIRST OIL IMPACT 1/

| Spill Site March Conditions | Nautical Miles of Shoreline | September Conditions | Nautical Miles of Shoreline |
|---|---|---|---|
| Birch Point to Cherry Point | 10.0 | Birch Point to Cherry Point | 10 |
| Point Doughty to Racoon Point | 5.0 | | |
| Patos Island | 2.5 | | |
| Sucia Island | 9.0 | | |
| Matia Island | 2.0 | | |
| | 28.5 | | |
| Canada, East Point, Saturna Island | 1.0 | | |

Source: Stewart 1978; Oceanographic Institute of Washington 1979b

1/ At-berth spill: Cherry Point

### Biological Components

Marine biological resources in the vicinity of Cherry Point include, scallops, intertidal hardshell clams, salmon, and bottomfish. The distribution of these resources can be found in Map Addendum. To the north of Cherry Point are winter and spring Pacific herring spawning grounds and habitats for waterfowl. To the south are Pacific herring spawning grounds, Dungeness crab beds, and numerous waterfowl nesting and/or roosting habitats.

No major construction impact could be identified for this alternate port site.

During the operation phase chronic at-berth oil spills would degrade the water quality in the vicinity of Cherry Point. As a consequence, those marine resources having sport and commercial values could become tainted by seawater-soluble fractions of crude oil.

A large in-transit or at-berth oil spill would present serious pollution problems in the Strait of Georgia. The oil-spill trajectories indicate that oil would also affect Canadian marine resources. Of significance would be a landfall of the oil at Sucia Island, a state wildlife refuge, and Matia Island, a national wildlife refuge, and on the northern coastline of Orcas Island. Alden Bank, a harbor seal area, would also be severely impacted. High mortality of herring and marine waterfowl would be expected.

No significant marine impact would occur if the berths were removed during the abandonment phase.

## Terrestrial Vegetation

It is assumed the location of the onshore storage facility would be within a few miles of Cherry Point. This area lies entirely within the Puget Sound Forest Area. It is also assumed that 300 acres of land would be committed to use for the storage facility during the life of the project. This would include agricultural land as well as forested areas.

No federally proposed species of threatened or endangered plants are known to occur in the area. No assessment was made as to the presence of Washington's rare, endemic, threatened, or endangered flora.

The 17 miles of pipeline corridor under this alternative would traverse 2 miles (12 percent) of forested areas and 15 miles (88 percent) of farmland. The corridor would parallel an existing pipeline corridor along its entire length; however, it is uncertain how much of the existing corridor would be utilized for the new pipeline. A construction corridor 90 feet wide would require the clearing of 22 acres of forest and 163 acres of farmland. The maintenance corridor would be somewhat less. The forested areas are mostly second-growth woodlots, with Douglas-fir dominant.

Areas of special concern along this segment include Lake Terrell State Game Refuge and Tennant Lake with its associated marshes. These areas are particularily sensitive to construction and oil spill damage because of the wide variety of animal and plant life which inhabit the marshes.

## Terrestrial Wildlife

The area proposed for the storage facilities supports wildlife associated with agricultural and forest land.

The proposed corridor crosses predominantly farmland, interspersed with small woodlots which provide considerable "edge" habitat. Game species include ring-necked pheasants, California quail, band-tailed pigeon, mourning doves, rabbit, and deer. Species associated with farmland are generally not as sensitive to disturbance as "deep woods" species, so impacts on upland wildlife are not expected to be significant.

Lakes Terrell and Tennant and their adjacent marshes are two important habitat areas close to the proposed route. Lake Terrell, within 0.5 mile of the alternate route, is centered within a 1,051-acre Wildlife Recreation Area. The north end of the lake is a game refuge. The alternate route passes within a mile of Lake Tennant, which is a 100-acre lake and marshland. The east side is owned by the state of Washington, and the west side is a private hunting club. These lakes, marshes, and adjacent agricultural lands are used as a migration stop for waterfowl heading south from British Columbia, and as breeding and feeding areas for pheasant and other resident species. Furbearers, such as beaver and muskrat, also utilize these habitats. A prime concern would be for birds and mammals associated with these wetland areas, which could be disturbed by construction activities particularly during breeding or migration times.

An oil spill during the operation phase could degrade agricultural lands, in addition to polluting local riparian habitat and wetlands around Lakes Terrell and Tennant and endangering migrating, wintering, or resident birds and resident mammals.

Threatened species in Washington include the northern bald eagle and the trumpeter swan. A northern bald eagle nest located in the Neptune Beach area near the Lummi Indian Reservation would be approximately 1 mile from the pipeline corridor. Since the Atlantic Richfield Company refinery and storage facility are already located in the vicinity, no additional disturbance of the nest is anticipated during construction or operation of the alternate port and pipeline route.

## Cultural Resources

The following material is based in part on a preliminary impact assessment and mitigative recommendations prepared by the University of Washington Office of Public Archaeology (TMC 1979).

Current records of prehistoric and historic culture indicate that four currently known cultural resource sites could be affected by this alternative port and pipeline route. The Golgatha Church site (45WH 30) is located on the Atlantic Richfield refinery property and, according to existing archaeological documents, possibly extends into the northwest corner of the proposed onshore storage facilities site. Activities associated with onshore storage facilities construction would disturb the existing topography and could significantly alter any existing archaeological remains. However, areas associated with previous construction of the Atlantic Richfield refinery have already been disturbed. These disturbances may have damaged or destroyed any existing archaeological remains at the site. The precise nature, extent, and condition of this particular site's deposits have not been determined. In addition, there are three prehistoric campsites located on the alternate pipeline corridor approximately at pipleline mile 11.

## Visual Resources

Landscape character in the vicinity of the Cherry Point site is generally rural, except an area that is zoned industrial and is currently used by several industries including Atlantic Richfield, Mobil, Puget Sound Power & Light, and Intalco. Three of these industries have extensive onshore development and berthing facilities in the Strait of Georgia. Most of the surrounding land is agricultural, and no significant recreation areas are located close to the proposed port facilities.

Construction of the onshore storage facility would cause high visual impact for the short-term which would diminish as it blended into the existing oil-related industrial complex.

The alternative pipeline segment traverses generally rural areas within existing rights-of-way. During construction, impacts would be significant until vegetation was reestablished.

## Land Use

Land use in the immediate vicinity of the site is dominated by an existing Atlantic Richfield refinery and ancillary facilities which cover approximately 1,200 acres. Other significant uses of land within a 5-mile radius of the Cherry Point site include:

A 1,400-acre Intalco Aluminum Corporation reduction plant about 2 miles southeast of the proposed onshore storage facility.

A Mobil Oil Company refinery which occupies 840 acres located about 3 miles southeast of the proposed port, adjacent to the Intalco site. Mobil receives crude oil by tanker and ships out much of the finished product through its own dock.

Birch Bay State Park (192 acres), approximately 2 miles northwest of the proposed port.

The Birch Bay resort area north of Birch Bay State Park, which provides for many activities including swimming, boating, fishing, golfing, and horseback riding. About 40 business enterprises are located along Birch Bay Drive. In addition, several hundred cottages serve as second homes. Construction of additional housing units is underway.

The Blaine Air Force Station (about 40 acres) located 3 miles north of the proposed port.

The Lake Terrell State Wildlife Recreation Area, about 2 miles east of the proposed onshore storage facilities, which contains nearly 1,200 acres of land for recreational use.

The Lummi Indian Reservation, located about 4 miles to the southeast. The reservation land is used primarily for agriculture and forestry. An aquaculture project is located on the Lummi Bay side of the reservation.

The alternate port site is generally compatible with adjacent land use, and should not conflict with existing land use in the surrounding area.

The pipeline corridor would traverse agricultural land including pasture, hayfields, and cropland. Construction impacts on farmland would be temporary, and since the alternate pipeline segment would be on existing right-of-way, no changes in actual land use are expected.

No significant impacts on planned land use are expected to occur from the development of facilities associated with the proposed project.

## Transportation and Utility Networks

### Marine Traffic

Tanker traffic to the Cherry Point berthing facility would transit the Strait of Juan de Fuca and Rosario Strait before entering the Strait of Georgia where the berth would be located. Increase in vessel traffic would be significant.

### Roads and Highways

Access to the Cherry Point site is via the existing primary and secondary highway systems that currently service existing industrial facilities in the area. Additional traffic volume generated by construction activity should be similar to that during the construction of the existing refineries and pipeline and less than that generated by the larger Intalco facility.

A work force of 34 would be employed to operate and maintain the proposed facilities at Cherry Point. The impact on existing highway traffic patterns resulting from operation-generated traffic is expected to be negligible.

### Railroads

Two major rail lines, the Burlington Northern and the Milwaukee Railroad, provide service to the Cherry Point area. Most construction materials for the port and pipeline would be shipped to staging areas by truck. It is anticipated that limited delivery of construction materials by rail should place no undue burden on existing railroad facilities. No significant adverse effects on railroad systems are expected.

### Airports

The Bellingham International Airport provides commuter air service to the area. Project-related use of available air services in the area is expected to be minimal. With the possible exception of some minor personnel movements, construction and operation movements would use other transportation. The proposed project is expected to cause no significant impacts on existing air traffic flow patterns.

### Electrical Facilities

Approximately 10 MW would be required to run pumps at the onshore storage facilities, decreasing the area's electrical power supplies.

### Recreation

Construction of the port facility is not expected to significantly alter the recreational opportunities or interests in the area.

Operation of the berthing facility would increase tanker traffic in the vicinity of Cherry Point. The tankers would be operating in an established traffic lane for commercial vessels, so pleasure boaters would not have to cope with new, commercial uses of the waterways.

A major oil spill at Cherry Point could affect sport salmon fishing in the area. Nonsalmon sport fishing could be impacted from Boundary Bay to the vicinity of Orcas Island. Offshore shellfishing would be lost from Boundary Bay to Orcas Island for a minimum of 4 years. Recreational home development in the area could be damaged by oil-polluted beaches and loss of visual quality. A minimum of 20 shore-side recreational parks and marinas could be impacted. Oil-fouled gear and boats and diminished recreational suitability could affect an indeterminate number of recreationists. Use of three vicinity parks in 1978 was 1.5 million visits. Pipeline leaks or ruptures could have major impacts on inland recreational resources, such as Lakes Terrell, and Tennant. Oil contamination of the Nooksack River would be considered a serious impact by the State of Washington. The Nooksack River is afforded protective status by the Shorelines Management Act of 1971.

### Social and Economic Conditions

The Cherry Point alternate port and pipeline segment would have socio-economic effects primarily in Whatcom County. The area surrounding the site is largely urban and industrial, with oil-related industries currently operating in the vicinity. The closest urban area is Bellingham, which is 12 miles from the proposed port facility.

Construction would take place over a 20-month period, with peak employment of about 400 workers. As much as 50 percent of the labor force might come from outside the local area. Approximately 22 percent (44 of these 200 nonlocal workers) would establish temporary residence in the area. Fifty-nine percent of the nonlocal workers (118 workers) would commute to the area on a weekly basis, returning to nonlocal residences for the weekend. The remaining 19 percent of the nonlocal workers (38 workers) would commute on a daily basis from outlying areas. A population increase of 982 persons could result from construction. This increase in the county population is not considered to be significant.

The temporary housing market (hotels, motels, and camping facilities) in Whatcom County would be strained for a relatively short duration during peak construction (approximately 3 months). Competition with tourists for transient housing and trailer parks would occur during the summer.

Construction of the facility is not expected to significantly influence either the overall level of employment in the county or the average per capita income. However, the project would provide a short-term stimulus to the construction and related industries, and unemployed workers may find work as a result of the project.

Operation of the terminal, storage, and pipeline facilities at Cherry Point would create about 36 new jobs. No significant impacts on county employment characteristics are expected as a result of employment associated with operation and maintenance of the facilities.

Assuming all of the operation personnel relocated in Whatcom County, the additional 36 families could cause an increase of 38 school-age children (assuming 1.46 children/ household with 72 percent of these of school age). The Bellingham School District has existing capacity for 40 additional students. Some of the 38 school-age children would probably attend schools located in other school districts in Whatcom County. The resulting increase of 38 school-age children in a system with an enrollment of 18,000 students should cause no appreciable effects on public schools.

No significant impacts to medical facilities or fire and police protection are expected from construction or operation.

Projected sales tax revenue from project construction would amount to approximately $4,690,400 for the state, and $509,830 for Whatcom County. The estimated capital cost for the system is $101,966,000 in Whatcom County (port and pipeline). Estimated annual property tax revenues are shown in table 9.7-2.

TABLE 9.7-2 PROPERTY TAX REVENUES FOR CHERRY POINT ALTERNATE
(in thousands)

| County Port and Pipeline Construction Cost January 1, 1979 Estimate | Equalization Ratio | Assessed Valuation | Equalized Value of all Real and Personal Taxable Property (1978 Local Tax Base)1/ | Assessed Valuation of Route Percent | Average Tax Rate2/ | Estimated Tax Yield |
|---|---|---|---|---|---|---|
| Whatcom $101,9663/ | 77.2 | $78,717.6 | $2,414,431.7 | 3.3 | 14.48 | $1,139.8 |

1/ Washington Department of Revenue 1979
2/ Assumes that tax levy rates would not decrease as a result of the increase in assessed valuation attributable to the project
3/ TMC 1979

## BURROWS BAY

This alternative considers a port at Burrows Bay, where all crude oil arriving by tanker would be unloaded and moved by pipeline to the onshore storage facility. This alternative includes a sea island type berth with pipelines to shore, and a storage facility consisting of eight 500,000 barrel tanks, and a booster pump station.

Tankers at berth would discharge crude oil to a booster pump station onshore which would pump the oil through a 48-inch pipeline approximately 7 miles to the onshore storage facility. The onshore storage facility would be located at March Point adjacent to the existing Trans Mountain pipeline. From March Point a new 30-inch pipeline would run within the existing Trans Mountain right-of-way to the international boundary at Sumas, approximately 51 miles (see figure 9.7-1.

Construction of the transshipment port at Burrows Bay is prevented by an amendment to the Marine Mammal Protection Act (PL 95-136).

## Climate

The general climate of western Washington has been previously discussed in the Cherry Point alternative.

No impacts on climate are anticipated for this alternative port site.

## Air Quality

Data for this area indicated that Anacortes and March Point, the closest industrial areas to Burrows Bay, were occasionally in violation of the ambient $SO_2$ standards. No ambient air quality standards were being violated at Burrows Bay. The Washington Environmental Profile (EPA 1978) indicates that there is no evidence that the primary $SO_2$ standard is being violated in Skagit County.

During the operation phase, emissions from the port and onshore facilities would be similar to those associated with the primary site. No air quality modeling was performed for the Burrows Bay site. No quantitative determination of impacts on air quality can be made.

## Noise

Construction and abandonment activities would temporarily increase noise levels. Noise generated during operation of the marine terminal would be primarily due to the booster pumps at the unloading dock (about 64 dBA at 100 feet). These noise increases could affect rural residents near the proposed facilities.

## Topography and Geology

The topography along this alternate route varies from moderately steep hills to broad flat lowlands. From the sea island berth to the storage facility, elevations range from sea level to 250 feet. The storage facility site at March Point is at an elevation of about 30 feet. From here the proposed pipeline segment descends to sea level at the Skagit Flats. The route crosses about 10 miles of the Skagit Valley and gradually rises to an elevation of about 15 feet where it joins the proposed route.

Construction, operation, and abandonment of an oil port at Burrows Bay and the attendant pipeline would result in relatively minor topographic impacts, consisting largely of landscape alterations.

The geologic materials on Fidalgo Island in the vicinity of the port and pipeline route are varied in composition. Near Alexander Beach pre-Devonian intrusive rocks (mainly diorite) occur at or near the surface and extend into the middle of the island. Along the eastern side of the island, Mesozoic sedimentary and volcanic rocks crop out at the surface. Scattered deposits of Quaternary glacial drift occur on top of the bedrock along the pipeline route across the island.

Recent age alluvial deposits form the surface materials along the pipeline route across the Skagit lowland.

Harbor materials appear to be a thin deposit of mud and sand underlain by bedrock; no significant impacts have been identified. No significant impacts to the physical geology have been identified along the alternate pipeline route.

The Burrows Bay alternate port and the pipeline from the port to the Canadian border are located in an area of moderate to high seismic activity, classified as a Seismic Risk Zone 3 (maximum earthquake damage expected). However, no known active surface faults have been identified near the proposed alternate facilities. Less than 10 significant earthquakes (Intensity V or greater) with epicenters within 10 miles of the proposed pipeline route have occurred since about 1841. Potential liquefaction of saturated sands in the Skagit lowland is possible, but site investigation would be required to substantiate whether this hazard exists along the pipeline route.

## Soils

The soils at the alternate port and along the pipeline route to Fidalgo Bay are mostly shallow, very rocky, and overlie bedrock. Soils along the segment of pipeline east of Fidalgo Bay and in the Skagit lowland are predominantly silt loam and loam in texture with 0-3 percent slopes. Dominant soils are Puget, Puyallup, and Sumas. Impacts to the soils from construction of the alternate facilities would be greatest in the steep-sloped and rocky soils on Fidalgo Island. Soil losses resulting from construction along the nearly level segment of the route east of Fidalgo Bay would be minimal. Vegetation is expected to reestablish quickly in disturbed areas.

## Aquatic Resources

### Physical Components

The proposed alternate port, onshore storage facilities, and pipeline segment would not be located adjacent to or across any major surface water bodies. Ground water may be contained in the glaciofluvial and alluvial deposits to the east of Burrows Bay along the proposed pipeline route. Potential impacts to near-surface ground water in glaciofluvial and alluvial deposits along the pipeline segment would be similar to those discussed in Chapter 8. This alternative would cause impacts to approximately 15 streams compared to 43 for the proposed route, resulting in lesser impacts on water resources than those of the proposed route.

### Biological Components

Stream crossing locations and fishery resources along this pipeline segment would be the same as the last 10 identified in Chapter 8. Several other crossings would also occur. This alternative would cause lesser impacts on fisheries resources than the proposed route since it would impact fish in about 15 locations compared with 43 for the proposed route.

## Marine Resources

### Physical Components

Entrance to Burrows Bay can be achieved through channels between Fidalgo Head and Burrows Island (controlling depth of 90 feet); between Burrows Island and Allan Island (controlling depth of 108 feet); between Allan Island and Williamson Rocks (controlling depth of 198 feet); or between Williamson Rocks and Langley Point (controlling depth of 196 feet).

Between October and May, areas sheltered from the Strait of Juan de Fuca would experience maximum wave heights of less than 4 feet. Exposed areas might experience waves prevalent in the eastern Strait of Juan de Fuca. The tidal currents and tidal ranges within Burrows Bay would be similar to those at the entrance to Rosario Strait and in the Strait of Juan de Fuca. Currents may attain speeds of 2 to 5 knots varying with the tidal range and the influence of wind (OIW 1974).

Marine water in Burrows Bay is a mixture of ocean and river water. Flushing action in Burrows Bay by currents may be somewhat restricted due to the presence of Burrows and Allen Islands to the west. Therefore, water quality characteristics may be somewhat different from those occurring further offshore in Rosario Strait. Burrows Bay and adjacent marine water has been designated Class AA. Water quality impacts would be similar to those discussed in Chapter 8.

### Oil Spill Risk Analysis

Vessel transit distance from Buoy J to Burrows Bay is 93 nautical miles. The annual frequency of an oil spill is expected to be one spill every 3.83 years. The size distribution of these spills is shown in Chapter 8. The estimated frequency of fire for in-transit tankers is expected to be 97 years and the estimated frequency for explosions in in-transit tankers is expected to be 93 years. A bunker barge spill, greater than 2.4 barrels but less than 10 barrels, could occur once every 4.65 years for 205 port calls and once every 2.34 years for 407 port calls. A tank farm spill, greater than 2.4 barrels but less than 10 barrels, could be expected once every 2.94 years. Fire and explosion at the storage facility, for damages greater than $1,000 but less than $10,000, could be expected once every 62 years. The frequencies of magnitudes for oil spills, bunker spills, and fire and explosion can be found in Chapter 3. The frequency of oil spills for the pipeline segment is expected to be one spill every 7.58 years (TMC 1979).

Tankers approaching Burrows Bay from the Strait of Juan de Fuca must pass over a rapidly shoaling area between Point Colville and Lawson Reef. At this location a hypothetical in-transit tanker grounding was considered to occur during March and during September oceanographic and meteorologic conditions. No estuarine flow was included in the trajectories simulation model since little is known about the flows in this region. The trajectories are shown in Map Addendum. A March grounding and oil spill would initially impact the shorelines of Allan and Burrows Islands, the shoreline from Iceberg Point on Lopez Island to Decatur Head on Decatur Island and all the shoreline of Smith Island. A September grounding and subsequent oil spill, the same shorelines, except Smith Island, could be initially impacted. Table 9.7-1 gives nautical miles of shoreline most likely to be initially impacted.

The initial shoreline impact could occur at Flounder Bay 2 hours after the spill during a neap tide. After 8 hours the oil spill could move along the western shoreline of Fidalgo Island to Langley Point. The initial shoreline impacted would be about 3.8 nautical miles. During a spring tide the initial shoreline that might be impacted is southeast of Flounder Bay after 8 hours. However, there is a possibliity that the eastern shoreline of Allan Island could be impacted 6 hours after the spill. The initial shore impacted would be about 2 nautical miles.

TABLE 9.7-3 MOST LIKELY REGION OF FIRST OIL IMPACT FOR A SPILL AT THE ENTRANCE TO ROSARIO STRAIT

| Spill Site | March Conditions | Nautical Miles of Shoreline | September Conditions | Nautical Miles of Shoreline |
|---|---|---|---|---|
| Entrance to Rosario Strait | Allan Island | 2.3 | Allan Island | 2.3 |
| | Burrows Island | 2.8 | Burrows Island | 2.8 |
| | Iceberg Point to Decatur Head | 9.5 | Iceberg Point to Decatur Head | 9.5 |
| | Smith Island | 1.0 | | |
| | | 15.6 | | 14.6 |

Source: Stewart 1978; Oceanographic Institute of Washington 1979b

### Biological Components

Burrows Bay marine habitats are eelgrass beds, rock, mud, and open water. Numerous waterfowl and a high salmon population are found in the bay. Concentrated purse seine fisheries are concentrated in the northern part and at the entrance to the bay. Gill net fishing is concentrated in the southern approach. Sport salmon fishing is found throughout the bay. Bottomfishing is concentrated around Allan and Burrows Islands and within all passages into the bay Shrimp are concentrated in Burrows Bay. The general distribution of marine biological resources in the bay and adjacent Rosario Strait and Strait of Juan de Fuca can be found on the marine resource maps in the Map Addendum. Concentrations of waterfowl and of marine mammals in the vicinity of Burrows Bay are also indicated on the marine resource maps.

Construction of the submarine line would degrade water quality in the bay, entrance to Rosario Strait, and the eastern part of the Strait of Juan de Fuca. Suspended solids would create turbid water conditions. Organic debris, heavy trace metals, and chlorinated hydrocarbons absorbed on clay minerals could also contribute to marine water quality degradation.

Chronic oil spills during in-transit and at-berth operations would degrade the water quality in the bay and the adjacent straits. Such spills could result in tainting of harvestable marine resources and reluctance of sports and commercial fishermen to utilize the bay.

A submarine pipeline rupture would have a significant impact upon the bay, Rosario Strait, San Juan Archipelago, and the central basin of the Strait of Juan de Fuca. Water quality would be degraded until the oil is dispersed by natural processes. High waterfowl mortality could be expected and tainting of shrimp, intertidal clams, and crabs might occur in the affected areas. Sports and commercial salmon and bottomfishing harvests could also be severely curtailed.

## Terrestrial Vegetation

It has been proposed that the onshore storage facilities would be located near March Point. Most of the lowlands (below 100 feet) of the March Point peninsula are agricultural, with the highlands being occupied by forest of Puget Sound Forest Area. It is assumed that 300 acres of land would be necessary for storage purposes, as with the preferred location. Although no estimate of percent forest and percent agriculture can be given, it is likely that the majority of the area is occupied by agricultural lands. These lands would be removed from production for the life of the project. The impacts associated with the construction, operation, and abandonment of onshore storage facilities are addressed in chapter 8.

No federally proposed species of threatened or endangered plants are known to occur in the area. No assessment was made as to the presence of absence of Washington's rare, endemic, threatened, or endangered flora.

If a major oil spill occurred at the storage facilities, and the spill were to reach Padilla Bay, the Skagit River delta and salt marsh could be impacted. This area supports a wide diversity of wildlife and has been nominated for Natural Landmark status.

The 14 miles of pipeline corridor under this alternative traverses 6 miles of forest (43 percent) and 8 miles of farmland (57 percent). The pipeline parallels an existing pipeline corridor for about half of its length; however, it is not clear how much of the existing corridor would be utilized for the new corridor. Assuming no overlap, a construction corridor 90 feet wide would be necessary, requiring clearing of 65 acres of forest and 88 acres of farmland. The corridor maintained clear of vegetation for the life of the project would be somewhat less.

The impacts associated with construction, operation, and abandonment of a pipeline system is addressed in chapter 8.

One species which has been proposed for threatened status on a 1978 federal list by Ayensu & Defilips, Castilleja parviflora var. olympica, is known to occur on Fidalgo Island, north of Lake Campbell. No surveys have been conducted along the pipeline corridor to determine if this species is present. No determination was made as to the presence or absence of plants which are considered to be rare, unique, threatened, or endangered within the State of Washington.

An area of special concern along this pipeline route is the Skagit River delta and saltwater marsh. This area is particularly sensitive to construction and oil spill damage because of the wide variety of animal and plant life which inhabits the marshes. This area has also been nominated for Natural Landmark status.

## Terrestrial Wildlife

Terrestrial wildlife at the alternate port and along the alternate pipeline segment includes those species typical of agricultural, forest, and wetland habitats. A small amount of wetland habitat is crossed by this alternate route. The right-of-way would be initially cleared of vegetation, but with revegetation, wildlife would be expected to repopulate the area.

The corridor would cross Fidalgo Island which has extensive woodland tracts. A high concentration of resident and wintering bird species occupy inland habitats. The island's location along the coastal flyway route provides habitat for migratory waterfowl and shore birds. Fidalgo and Padilla Bays are frequented by bird watching and nature study groups. Game species include a medium to high deer and grouse density.

An estimated 140 acres of agricultural habitat near Widmarsh Junction would be cleared for construction of the storage facility. This habitat would be lost for the duration of the project.

Construction noise and dust may cause some short-term disturbance to wildlife. The existing right-of-way parallels a highway and railway so operational activities are not anticipated to cause any significant increase in the present level of disturbance to area wildlife.

Construction activities may disturb migratory and resident birds and resident mammals inhabiting nearby wetlands and bay areas, especially during breeding seasons.

Northern bald eagles occur along the coastal area of Rosario Strait. The Fidalgo and Padilla Bay areas are particularly noted as prime eagle habitat. These birds would probably avoid these areas during construction.

Oil spills and drainage into nearby wetland areas would adversely impact wildlife.

## Cultural Resources

The cultural resource sites listed in table 9.7-4 are found near this port alternate and pipeline route segment. There is high potential for discovery of additional archaeological and historical sites in the proposed construction areas, especially along the shoreline.

## Visual Resources

Construction of the port facilities would create a short-term high visual impact on the shoreline. Tanker movement is common in the area.

The storage facilities would require the clearing and leveling of approximately 140 acres and would cause a significant visual intrusion during construction; however, the impact would be short-term due to the present oil-related industry in the area.

The pipeline from Burrows Bay to the junction with the proposed route at Bayview would traverse rural areas on Fidalgo Island and then parallel the existing pipeline from March Point. Construction activities would cause temporary visual disruption. Operational impacts would be incremental along the existing pipeline right-of-way.

TABLE 9.7-4 ARCHAEOLOGICAL AND HISTORICAL SITES FOR BURROWS BAY PORT AND PIPELINE ROUTE SEGMENT

| County | Site Name | Site Type | Approximate Location |
|---|---|---|---|
| Skagit | 45SK16 | Shell midden | Allan Island |
| | Burrows Island light station 1/ | Historic lighthouse | Burrows Island |
| | 45SK42 | Shell mound | Pipeline Mile 3 |
| | 45SK43 | Shell mound | Pipeline Mile 3 |
| | 45SK45 | Shell mound | Fidalgo Bay |
| | 45SK 1 | Shell mound | Similk Bay, Pipeline Mile 5 |
| | 45SK17 | Shell midden cairn and burials | Similk Bay |
| | 45SK18 | Shell midden | Similk Bay, Pipeline Mile 6 |
| | 45SK58 | Campsite | Pipeline Mile 12 |
| | 45SK67 | Artifact locality and possible trail | Pipeline Mile 13 |
| | 45SK90 | Habitation site | Pipeline Mile 14 |

Source: TMC 1979

1/ Listed in National Register of Historic Places.

## Land Use

Allan and Burrows Islands and most of Fidalgo Island are presently rural in their land use. Skagit County has zoned the islands residential, as much of the land is marginal for agricultural production. Second home recreational developments are beginning to appear on Fidalgo Island, and are expected to continue to increase in number. The number of private property owners on the islands would increase as population increases, resulting in parcelization of land in the rural areas.

Private property owners comprise the largest land ownership category on Allan, Burrows, and Fidalgo Islands. Anacortes owns the property surrounding the Mt. Erie watershed, making the city the second largest landowner on Fidalgo Island. The State of Washington owns and operates Deception Pass State Park on the southern tip of Fidalgo Island. The only federally owned land occurs on a small portion of Burrows Island where the U.S. Coast Guard maintains a lighthouse station.

Only small portions of Fidalgo Island are currently industrialized, including March Point (already occupied by oil refinery facilities), and the west side of the Swinomish channel. The port at Burrows Bay would introduce an industrial land use into a relatively undeveloped coastline area.

The pipeline from the port facility at Burrows Bay to Whitmarsh Junction would traverse primarily undeveloped, rural land. Agriculture is not a prime land use in this area due to slope and soil management problems. From Whitmarsh Junction east to the prime route, the pipeline follows TMC's existing right-of-way. Temporary, short-term impacts, such as disruption of one growing season where farmland is crossed to nuisance-related effects in residential areas, would result from construction activities. Operational impacts would represent the incremental expansion of an existing land use.

## Transportation and Utility Networks

Vessel traffic congestion would not likely be a problem in Rosario Strait and Burrows Bay.

Highway access to Burrows Bay is limited to a two-lane roadway from Anacortes. Construction traffic would cause significant lowering of service levels on roadways and in nearby Anacortes where the nearest railroad is located.

Electric power demand for the Burrows Bay alternate would be approximately 10 MW, decreasing the regional electric power supplies.

## Recreation

The Washington Marine Atlas (1974) indicates that most of Burrows Bay is used as a sport salmon fishery, with particularly heavy fishing occurring in the vicinity of Langely Point. The western half of Burrows Bay and Allan Island are used as a nonsalmon sport fishery.

Burrows Bay is the site of a large number of vacation homes and other recreational developments. As such the entire area is used extensively for recreational boating. Skin diving occurs primarily off Burrows and Allan Islands. Several freshwater lakes are in the study area (Campbell Lake, Crater Lake, Lake Erie, Whistle Lake, and Hart Lake).

The tanker berthing facilities in Burrows Bay would be visible from boating areas offshore and from some recreational homes onshore. Tankers are not uncommon in this area. It is anticipated that no significant impacts to recreational activities would occur as a result of normal construction, operation, or abandonment activities associated with the berthing facilities or the pipeline. In the event of an oil spill, recreational activities would be curtailed for the duration of cleanup activities. Pleasure boating, bottom and salmon fishing in Burrows Bay, recreational shrimping and scuba diving are some of the activities that would be affected.

Construction of the pipeline segment from Burrows Bay to Whitmarsh Junction would disrupt recreational activities. Operational impact would not be significant. The pipeline from Whitmarsh Junction to the junction with the prime route follows existing rights-of-way. Construction and operation would represent incremental impacts of minor significance.

## Social and Economic Conditions

The Burrows Bay alternative port and pipeline segment would primarily affect socioeconomic conditions in Skagit County, and to a less extent in Island County. It is assumed that labor force requirements and capital cost to construct and operate this alternative port, onshore storage and pipeline facilities would be essentially similar to the Cherry Point alternative.

Construction would take place over a 20-month period, with peak construction employing about 400 workers. Assuming that 50 percent of the labor force is nonlocal, a population increase of 982 persons could occur in Skagit County as a result of construction. This represents a minor increase in total county population and is not considered significant.

The temporary housing market (hotels, motels, and camping facilities) in Whatcom County would be strained for a relatively short duration during peak construction (approximately 3 months). Competition with the tourist trade for transient housing accomodations and trailer park space would undoubtedly occur during the summer.

Construction of the facility is not expected to significantly influence either the overall level of employment in the county or the average per capita income. However, the project would provide a short-term stimulus to the construction and related industries and county unemployment may be reduced as a result of the project.

Operation of the facilities would create about 36 new jobs in Skagit County. No significant impacts on county employment characteristics are expected as a result of employment associated with operation and maintenance of the facilities.

If all of the operations personnel were to relocate to Skagit County, the additional 36 families could result in an increase of 38 school-age children (assuming 1.46 children/household with 72 percent of school age). Most of the schools in the area are already operating above capacity and would experience incremental increases in overcrowding as a result of the proposed project.

Community services in Anacortes would not be significantly impacted by the project.

No significant impacts are expected on medical facilities or fire and police protection from construction or operation of the alternate port and pipeline.

Projected sales tax revenue from project construction would amount to approximately $5,839,380 for the state, $529,120 for Skagit County, and $105,590 for Whatcom County.

The estimated capital cost for the system is $105,824,600 in Skagit County (port and pipeline) and $21,118,500 in Whatcom County (pipeline only). Estimated annual property tax revenues are shown in table 9.7-5.

TABLE 9.7-5 PROPERTY TAX REVENUES FOR BURROWS BAY ALTERNATE
(in thousands)

| County | Estimated Value of Construction Cost (January 1, 1979 Value) | Equalization Ratio | Assessed Valuation | Equalized Value of all Real and Personal Taxable Property (1978 Local Tax Base)[1] | Assessed Valuation of Route as Percent of Total County | Average Tax Rate[2] | Estimated Tax Yield |
|---|---|---|---|---|---|---|---|
| Skagit (port and pipeline) | $105,824.6 | 80.9 | $85,612.1 | $1,336,766.5 | 6.4 | 15.72 | $1,345.8 |
| Whatcom (pipeline only) | $21,118.5 | 77.2 | $16,303.5 | $2,414,431.7 | 0.7 | 14.48 | $236.1 |

Source: TMC 1979

[1] Washington Department of Revenue 1979.

[2] Assumes that tax levy rates would not decrease as a result of the increase in assessed valuation attributable to the project.

Burrows Bay

## PORT ANGELES

BLM considers Port Angeles to be an alternative to the TMC proposed port at Low Point. The TMC proposed crude oil transportation system could utilize tanker berthing on Ediz Hook and onshore storage facilities on Green Point as proposed for the NTPC system.

TMC proposes a 630,000 barrels per day ultimate throughput pipeline system which would require unloading facilities, two submarine pipelines, and an onshore storage facility. BLM determined that the TMC system could use a fixed berth unloading facility, located on Ediz Hook, capable of unloading two 200,000 dead weight ton class tankers simultaneously. Two submarine pipelines, approximately 48 inches in diameter, would transport the crude oil to the onshore storage facility, possibly located on Green Point. This facility, similar to the Low Point proposal, would require about 240 acres of land and be capable of storing 4 million barrels of crude oil for delivery into the proposed pipeline system. This pipeline system and route, except for the initial 28 miles, would be same for TMC as proposed in chapter 1 and described and analyzed in chapter 8.

Construction impacts for the tanker unloading facility on Ediz Hook, the two submarine pipelines and the onshore storage facility on Green Point would be similar to impacts described for the NTPC system in chapter 3.

Operational impacts on marine resources and water quality at the Port Angeles unloading facilities would be similar to the impacts for the proposed NTPC system.

Comparative oil spill risk analysis for the NTPC system shows little difference between Port Angeles and a single point mooring at Low Point using throughput capacities of 709,000 and 933,000 barrels per day. Low Point is preferable from an in-terminal risk standpoint, and Port Angeles from an at-berth risk standpoint. The in-transit advantages at Low Point must be weighed against the disadvantages of exposure to weather and sea conditions of the SPMs as opposed to the shelter of Port angeles harbor.

The ultimate throughput fpr TMC (630,000 bpd) is lower than the initial throughput (709,000 bpd) proposed by NTPC. Therefore, the oil spill risk for in-transit and at-berth, whether using a single point mooring at fixed berth, would be somewhat less than the risk associated with the initial throughput.

These conclusions for operational impacts of the TMC system using the Port Angeles port site were based upon judgments about the Low Point and Port Angeles sites, using OIW (1978a, b, and c) oil spill risk analyses developed for the NTPC system. The comparisons could be considered acceptable for preliminary analysis of environmental impacts; however, no incremental and combined oil spill risk analyses have been made for the TMC port if located in Port Angeles harbor.

## ROUTE SEGMENT ALTERNATIVES

### PORT WILLIAMS, WHIDBEY ISLAND, CAMANO ISLAND

### (Across Puget Sound)

This alternative pipeline route segment would depart from the proposed route near Morse Creek at pipeline mile 25, and head northeast then east to the Port Williams area (figure 9.7-1). A 14-nautical-mile submarine crossing of the eastern Strait of Juan de Fuca would then be made to Point Partridge on Whidbey Island. On the Island, the route would head north-northeast to a point north of Oak Harbor and south of the U.S. Naval Reservation, and then west to a location near Strawberry Point. A submarine crossing of Saratoga Passage to Brown Point on Camano Island would then be made. The pipeline route would then head southeast to Stanwood, where it would join the proposed route at pipeline mile 83. Total distance for this alternate route would be 52 miles compared to 58 miles for the proposed route.

#### Climate and Air Quality

Climate and air quality conditions and impacts along the pipeline route alternative would be similar to those discussed for the proposed route. Fewer areas would be impacted by fugitive dust because less land area would be crossed by this route.

#### Noise

Noise generated from construction, operation, and abandonment procedures would be very similar to noise generated for the primary pipeline route. The rural residences near the alternate route would experience temporary high levels of noise during construction and abandonment.

#### Topography and Geology

The portion of the alternative pipeline segment on the Olympic Peninsula traverses gently rolling to nearly level glaciated uplands between an elevation of about 80 and 350 feet. From north of Port Williams to Whidbey Island the sea bottom depths range to about 300 feet. Across Whidbey Island the alternative route traverses rolling glaciated uplands between elevations of about 50 to 450 feet. From Whidbey Island to Camano Island the depth is about 60 feet. On Camano Island the route crosses glaciated uplands with elevations to 150 feet.

Construction of a pipeline along this alternative route segment would result in relatively minor topographic impacts similar to those discussed for the prime route and would consist primarily of landscape changes ranging from 10 to 25 acres/mile.

The land portions of the alternate pipeline segment are underlain by glacial drift primarily consisting of till and outwash and glacial-marine sediments. The sea bottom is composed of a variety of materials including rock, mud, sand, and gravel.

Impacts to the physical geology would consist primarily of minor alteration of geologic materials from excavation of the pipeline trench. During construction the potential for erosion and slope failure would increase slightly. The coastline north of Port Williams is considered unstable.

The entire route lies within Seismic Risk Zone 3 (maximum earthquake damage expected). The area has not felt an historical earthquake greater than Modified Mercalli Intensity VI. Seismicity and slope stability problems along this alternate route would be similar to those for the proposed route.

## Soils

The soils along the alternative route segment are predominantly deep gravelly, and loamy soils on glacial uplands. Along the Olympic Peninsula portion of the route, dominant soils are Elwha and Clallam loams. On Whidbey and Camano Islands, Whidbey and Hoypus gravelly loam and Bow loam are dominant. Slopes along the route generally range between 0 and about 30 percent.

Adverse impacts to soils from construction would be minor and similar to those discussed for the comparable segments of the proposed route.

## Aquatic Resources

### Physical Components

The alternate pipeline crossing of the Dungeness River and adjacent small streams are farther to the north than the proposed pipeline crossings. Water quality characteristics in these segments of the river and streams are not likely to be significantly different from those described for the proposed route.

Impacts on surface and ground water caused by construction and operation of the alternate pipeline segment would be similar to the impacts for the proposed route. Cumulative impacts on water quality would be less than for the proposed route since five fewer stream crossings would occur (12 for the proposed route and 7 for this alternative).

### Biological Components

This alternative route segment would cross seven streams supporting fisheries resources (table 9.7-6). Five of these streams are also crossed in the proposed route, but farther upstream. Two additional streams, Cassalery and Gierin Creeks, support searun trout and possibly coho and chum salmon. Impacts on fisheries resources would be less than for the proposed route where 12 streams would be impacted.

TABLE 9.7-6 PIPELINE CROSSING LOCATIONS ON SELECTED WASHINGTON STREAMS AND AFFECTED HABITATS, HATCHERIES, AND FISHERIES

| Main Stream | Approximate Pipeline Mile 1/ | Miles of Spawning Habitat 2/ | Significant Spawning Habitat 3/ | River Mile Crossing Location 4/ | Name and Location of Hatchery Facility 5/ | Indian Fishery 6/ | Remarks |
|---|---|---|---|---|---|---|---|
| Across Puget Sound Route Segment | | | | | | | |

1/ Approximate pipeline mile where crossing would occur.

2/ Approximate number of miles of spawning and rearing habitat for anadromous and resident salmon and trout on stream mainstem. Includes areas both upstream and downstream from proposed pipeline crossing.

3/ Location of significant spawning areas for anadromous and resident salmon and trout by river mile.

4/ Approximate location of proposed pipeline crossing by river mile from the mouth.

5/ Name and location of hatchery. River mile number is that of the main stream where fish released from the hatchery would enter.

6/ Name and location of Indian river fishery. Additional Indian fisheries currently in litigation.

7/ — line means no specific data were located in the sources referenced.

## Marine Resources

### Physical Components

Infrequent extreme wave heights can reach 15 feet, and current velocities off Dungeness Spit to Point Partridge can reach 1 to 3 knots during ebb tide. In Saratoga Passage, maximum flood currents are about 0.3 knots while maximum ebb currents are around 0.5 knots (U.S. Department of Commerce 1973). Physical and chemical oceanographic conditions in the Strait of Juan de Fuca in the corridor crossed by the alternative pipeline segments are similar to the proposed route.

Marine water classification for the Strait of Juan de Fuca is considered extraordinary. Marine water in the Whidbey Basin (Skagit Bay, Saratoga Passage, etc.) is considered excellent (Washington State Department of Ecology 1977). The difference in water classification is a result of restricted flushing, industrial, domestic, and agricultural input into the Basin.

Impacts on marine water quality would be similar to those for the proposed route. However, the alternate Puget Sound crossing would be several miles longer than either of the crossings for the primary route. Therefore, burial of the pipeline would suspend more bottom sediments and marine water quality could be degraded.

The submarine pipeline crossing would pass under ship traffic lanes, and a navigational precautionary area. A ship in distress, due to loss of engines or steerage, would probably drop anchors. Should this occur in the traffic lanes or in the precautionary area, there is the possibility of a submarine pipeline rupture caused by anchor dragging.

### Oil Spill Risk

Employing the risk analysis methodology, the spill exposure along this alternate route segment are shown in table 9.7-7.

TABLE 9.7-7 ESTIMATED FREQUENCY OF PIPELINE SPILLS
FOR THE CROSS SOUND ALTERNATE ROUTE SEGMENT

| Approximate Pipeline Miles | Traverse | Length (miles) | Frequency (years) 1/ One Spill Every: | Average Spill Size (bbl) |
|---|---|---|---|---|
| 25 - 38 2/ | Morse Creek to Coastline | 13 | --- | --- |
| 38 - 55 | Eastern Strait of Juan de Fuca | 17 | 69.93 | 115 |
| 55 - 70 | Whidbey Island | 15 | 30.30 | 622 |
| 70 - 73 | Saratoga Passage | 3 | 400 00 | 115 |
| 73 - 76 | Camano Island | 3 | 151.52 | 622 |

Source: TMC 1979

1/ Rates: Land Spill Rates = 0.0022 spills/mile/year
Submarine Spill Rates = 0.00084 spills/mile/year.

2/ Spill risk for this initial sector of the alternative route is covered in chapter 8.

Simulated oil spill trajectories from hypothetical underwater pipeline ruptures in March and September are shown in the Map Addendum. Since little is known about estuarine flow in the Central Basin of the Strait, only tidal currents and wind stress were used in the simulation model. Initial impact zones (first landfall of oil) for spring and fall submarine pipeline oil spills are given in table 9.7-8.

No trajectories for underwater pipeline ruptures between Strawberry Point and Brown Point are available.

TABLE 9.7-8 MOST LIKELY REGION OF FIRST OIL IMPACT
FROM A SUBMARINE PIPELINE SPILL

| Spill Site | | | |
|---|---|---|---|
| March Conditions | Nautical Miles of Shoreline | September Conditons | Nautical Miles of Shoreline |
| Deadman Bay to Eagle Point | 6.5 | Deadman Bay to Eagle Point | 6.5 |

### Biological Components

Marine resources in and around the central basin of the Strait of Juan de Fuca are salmon and bottom fish species which are sought by commercial and sports fishermen. These resources are probably the most utilized in the area. Other marine resources are:

1. Pacific oysters in Dungeness Bay, Sequim Bay, and Whidbey Basin subtidal hardshell clams northwest and east of Dungeness Spit, in Sequim and Discovery Bay, off Green Point, around Protection Island, of the western coastline of Whidbey Island, and in Admiralty Inlet; intertidal hardshell clams in Dungeness Bay, Sequim Bay, Discovery Bay, Admiralty Inlet, San Juan Archipelago, and Whidbey Basin; Dungeness crabs in Dungeness Bay, Admiralty Inlet, San Juan Archipelago, and Whidbey Basin; shrimp in the San Juan Archipelago, and Whidbey Basin; scallops in Admiralty Inlet.

2. Surf smelt spawning areas in Dungeness Bay, Sequim Bay, Discovery Bay, Admiralty Inlet, and Whidbey Basin; herring fishing and spawning areas in Dungeness Bay, Sequim Bay, Discovery Bay, Admiralty Inlet, Whidbey Basin, and San Juan Archipelago.

3. Major waterfowl breeding, roosting and/or feeding areas on Dungeness Spit, in Dungeness Bay, Sequim Bay,Discovery Bay, Admiralty Inlet, on Protection Island and Smith Island, Whidbey Basin, and in the San Juan Archipelago.

4. River otter habitats in Dungeness Bay, Admiralty Inlet, and in the San Juan Archipelago; harbor seal haul out and/or pupping areas in Dungeness Bay, on Protection Island and on Smith Island; elephant seal haul out and/or pupping areas on Dungeness Spit, in Sequim Bay, Discovery Bay, on Protection Island and Smith Island, Admiralty Inlet, and in Whidbey Basin; harbor porpoise forage areas off Dungeness Spit, and throughout the San Juan Archipelago; Dall porpoise forage areas in the San Juan Archipelago, in Admiralty Inlet, off Dungeness Spit, and Protection Island; minke whale forage areas throughout the San Juan Archipelago, Whidbey Basin, and central basin of the Strait of Juan de Fuca; and gray whale forage areas off Green Point and Dungeness Spit, in Admiralty Inlet, and in the central basin of the Strait.

The general distribution of these marine resources and mammal sightings are shown on the marine resource maps in the Map Addendum. Marine habitats, including sensitive habitats such as kelp beds, eelgrass beds, and saltmarsh in the vicinity of the TMC alternate submarine pipeline route are indicated on the marine resources maps in the Map Addendum.

Construction of the submarine pipeline between the vicinity of Port Williams to Point Partridge would degrade water quality in the eastern strait, Dungeness Bay, Sequim Bay, Discovery Bay, and Admiralty Inlet. This degradation would be a result of increased suspended solids which would cause turbid water conditions, increased surface temperatures, decreased dissolved oxygen. Also soluble and particulate adsorbed heavy trace metals, nutrients, chlorinated hydrocarbons, and organic debris could be introduced to the water column. These sediment components would further degrade water quality in Skagit Bay and Saratoga Passage and would be particularly severe because of the restricted flow and slow flushing in the Whidbey Basin.

Subtidal clam beds off Port Williams and around Protection Island would be partially destroyed. Repopulation in the destroyed beds on the pipeline transit should occur with 1 year to 18 months and reproducing adult clams should be present in 3 to 4 years. During construction those clams not destroyed could aquire excess burdens of heavy trace metals and chlorinated hydrocarbons. However, after construction is completed, the excess heavy trace metals and chlorinated hydrocarbons would be slowly eliminated.

Waterfowl off Port Williams, around Protection Island in Saratoga Passage, and in Skagit Bay would be disturbed by construction activity and would avoid these areas. Any displacement of waterfowl would be local and temporary.

Harbor seals on Protection Island and Smith Island could be harassed by construction activities which could result in a significant impact if the cows are nursing. The pups could be abandoned and die from starvation or predation.

A submarine pipeline rupture would significantly degrade water quality throughout the eastern part of the Strait, Dungeness Spit and Bay, Sequim Bay, Discovery Bay, San Juan Archipelago, and Admiralty Inlet. Resources impacted would be subtidal clams, marine waterfowl, and marine mammals. Commercial and sports salmon and bottom fisheries would also be significantly impacted.

Waterfowl would suffer high mortality, particularly in Dungeness Bay, on Protection Island and Smith Island. During breeding season low egg hatchability would be expected. Oil trajectories for a pipeline rupture are shown in Map Addendum.

No information is available on oil spill trajectories for the Whidbey Island-Camano Island leg of the submarine pipeline. However, a pipeline rupture would significantly impact shrimp and crab species, sports and commercial salmon fisheries. High mortality of waterfowl in the Skagit saltmarsh and in Saratoga Passage would be expected. Also low waterfowl egg hatchability would occur. The saltmarshes and mud flats in the Whidbey Basin could retain spilled oil for several years.

Fishes, porpoises, and whales would probably avoid oil contaminated areas. Fish could, however, could become tainted from petroleum components by feeding on lower marine organisms. Salmon would be indirectly impacted by loss of a year-class of herring which could occur 2 or 3 years after high mortality in herring roe. "

## Terrestrial Vegetation

This alternate route segment is 52 miles long and traverses marine water, agricultural land, and forest lands. It lies entirely within the Puget Sound Forest Area. The forested areas are almost entirely second growth woodlots of Douglas-fir.

A construction corridor 90 feet wide would be required, committing 153 acres of forest and 185 acres of farmland to pipeline corridor for the life of the project.

Areas of special concern along this segment which could be irreparably impacted include Gray's Marsh (just north of Sequim) and the Skagit River delta and salt marsh. These areas are particularily sensitive to construction and oil spill damage because of the wide variety of animal and plant life which inhabit the marshes.

No plants which have been proposed for federal status as threatened or endangered species are known to occur along the route. No search was conducted to determine whether any species may be affected locally, but since they are generally only rare within the state, their overall distribution would not be seriously impacted.

## Terrestrial Wildlife

The alternate route segment crosses prime habitat for shorebirds and water-oriented birds. Upland areas of the corridor are composed of approximately equivalent amounts of forest and agricultural habitats. Associated species would be similar to those of the prime route. A rating of habitat quality and wildlife potential was conducted at 10 evaluation points along the route (table 9.7-9).

The alternate route would traverse good quality game lands with higher pheasant, waterfowl, and deer populations. Whidbey Island and a very small part of Camano Island have an abundance of deer and a medium to high pheasant and waterfowl density.

Important wildlife areas in the vicinity of the alternate corridor segment include: Dungeness National Wildlife Refuge, Partridge Point, and Penn Cove, which provide habitat for large numbers of birds, especially migrating and wintering waterfowl; Jamestown Beach and Protection Island, which provide a major nesting area for cormorants, pigeon guillemots, rhinoceros auklets, and tufted puffins; and the tidal flats of Skagit Bay near Utsalady, which contains valuable habitat for waterfowl, bald eagles, furbearers, and other wildlife.

Impacts on wildlife (habitat loss and alteration, displacement of wildlife, increased stress, and associated changes in species composition) and the effects of an oil spill would be comparable to those for the proposed route. Similar terrestrial birds and mammals, including upland game species, would be impacted. Less forest habitat, however, would be affected on the alternate route.

Wintering and resident bald eagles (threatened status) have been observed at Green Point and the Morse Creek area. Areas near Utsalady on Camano Island and north of Oak Harbor on Whidby Island are noted as northern bald eagle habitat (Washington Department of Ecology 1979). No impacts on these species are expected.

Cultural Resources

The Olympic Peninsula portion of the alternate route segment crosses the Dungeness Valley and the Dungeness River which has been and still is important Indian fishing locality. European settlers farmed the flat portions of the valley such as Sequim prairie. Port Williams is one of the early coastal settlements in this region. The entire coastal margin of Whidbey Island was once intensely used by native occupants who exploited the nearshore shellfish resources.

The cultural resource sites along this route segment alternative are listed in table 9.7-10. Potential impacts to these sites and to any presently unrecorded sites would be the same as identified for the proposed route. There is potential for discovery of additional archaeological and historic sites along the proposed corridor, especially at shoreline areas at the crossings of the Dungeness River, the Strait of Juan de Fuca, and Saratoga Passage.

The proposed action may result in potential impacts to presently unknown cultural resources lying within the project area. Both the ethnographic and archaeological records indicate that the region's aboriginal populations used the area extensively for several millenia. However, on-site archaeological reconnaissance activities have focused on only a small portion of this area. In the absence of direct on-site inspection, it is not possible to conclude that no further significant cultural resources occur within the right-of-way of this alternative.

TABLE 9.7-10 ARCHAEOLOGICAL AND HISTORICAL SITES

| County | Site Name | Site Type | Approximate Route Segment Pipeline Mile |
|---|---|---|---|
| Clallam | McCleary School House | Historic | 8 |
| Clallam | Sequim View Cemetery | Historic | 11 |
| Clallam | Port Williams | Historic port site | 14 |
| Island | Central Whidbey Island Historic District 1/ | Historic land claims and structures | 31-33 |

| Island | 45IS12 | Prehistoric burials | 52 |

1/ The Central Whidbey Island Historic District has been designated the Ebey's Landing National Historic Reserve.

Visual Resources

Areas of potential public exposure to views of the pipeline right-of-way include highway and railroad crossings, residential, and recreation areas. The route would cross two highways, Highway 101 on the Olympic Peninsula and Highway 20 on Whidbey Island, and the Chicago, Milwaukee, and Pacific Railroad on the Olympic Peninsula. The alternative also crosses numerous local arterial and collector streets. On-shore and marine construction activities would be visible offshore from boats in the eastern Strait of Juan de Fuca, Saratoga Passage, and from points along the shorelines. High visual impact is anticipated during the construction phase persisting as low to none for the life of the project.

Extensive shoreline modifications North of Port Williams and on the west bluff (near Partridge Point) of Whidbey Island, plus the Saratoga Passage bluff cuts, are in foreground visual zones of vessels in Puget Sound and Saratoga Passage. The large bluff scars would irreversibly alter the landscape to such an extent that they would be visual intrusions indefinitely.

They would exceed maximum allowable contrast for visual management quality objectives for Class II, and are judged to be critically severe adverse visual impacts.

Construction activities through outlying residential areas near Oak Harbor would result in short term high visual impacts. During the operation phase visual impacts would probably decrease and be moderate to low.

Land Use

The alternate pipeline corridor would traverse parts of Clallam, Jefferson, and Island Counties. The portion within Jefferson County is entirely submarine pipeline and is not evaluated in this section.

The route predominantly crosses agricultural, pasture, and forest land. Urban fringe and residential areas account for less than 1 percent of the route. The remainder of the route traverses salt water, small amounts of fresh water, and wetlands.

Construction would cause short-term temporary impacts on agricultural land and nuisance-related impacts in urban and built-up areas (see table 9.7-11). The types of impacts on land use caused by pipeline construction and operation are described in Chapter 8.

Zoning and Comprehensive Plans

Interim zoning maps show that most of the alternate route within Clallam County passes through agricultural districts. The "Clallam County Shoreline Master Development Program" (Clallam County Shoreline Advisory Committee 1976), indicates that this route segment crosses three designated rural shoreline environments; McDonald Creek, the Dungeness River, and the Strait of Juan de Fuca.

The Interim Zoning Ordinance of Island County, Washington (1966) as amended, indicates the alternate route segment passes through rural and residential zoning districts. The Island County Comprehensive Plan, Planning Policy--Phase Two (1977) indicates that the right-of-way passes through areas designated for several land uses, with rural and agricultural uses predominating (NTPC 1978). According to the Island County Shoreline Management Master Program (1975) the pipeline route crosses four designated shoreline areas: Strait of Juan de Fuca-conservancy, Saratoga Passage-conservancy, Skagit Bay-shoreline residential, and Davis Slough-rural (NTPC 1978).

Transportation and Utility Networks

Submarine pipeline lay barges and associated marine traffic may cause temporary interference with existing marine traffic during burial of the pipeline. However, this represents a minor impact since there would be a large area of navigable water for vessels to maneuver around the construction area. The Saratoga Passage crossing should not present a significant hazard to marine vessel traffic or other submarine cables.

The terrestrial portion of the route would parallel existing corridors/rights-of-way for a considerable distance on Whidbey and Camano Islands. Two highway crossings would be required. The alternate segment crosses a Clallam County Public Utility District 69 kV transmission line in two places (pipeline miles 26 and 34). Possible impacts to other transportation and utility systems would be essentially similar to the proposed route described in chapter 8.

TABLE 9.7-11 CITIES, TOWNS, AND RURAL CENTERS ALONG THE ACROSS SOUND ALTERNATE ROUTE SEGMENT

| County | Name | Population | Distance from Pipeline Route Centerline | Approximate Pipeline Mile |
|---|---|---|---|---|
| Clallam | Agnew | NA 1/ | 0.1N | 30 |
| | Carlsborg | NA 1/ | 1.0S | 34 |
| | Sequim | NA 1/ | 1.5S | 37 |
| Island | Oak Harbor | 11,618 | 1.1S | 63 |

Sources: Washington Office of Financial Management, Population Trends 1977; U.S. Department of Commerce, Bureau of the Census 1977.

1/ Less than 2,500 inhabitants.

Since the same number of pump stations would be required in Clallam County (two), the impact on Clallam County PUD power supply would be essentially the same as that described for the proposed rout in chapter 8.

Recreation

Sport fishing and pleasure boating are important recreational activities on the Strait of Juan de Fuca. Fin and shellfish recreational fisheries, boating, and nearby beaches or day-use areas would be contaminated by oil spills or pipeline leaks. A rupture which would foul shellfish beds in the Dungeness National Wildlife

Refuge would be considered a critical impact. Shellfish bed re-establishment would take a minimum of four years. Over 100,000 recreational visits occurred in 1978.

Loss of recreation resources in the area could occur in oil-fouled areas during the period of containment and cleanup, and for an additional unknown amount of time needed for the reestablishment of pre-spill conditions.

Recreational use of area states shoreline parks was more than four million visits in 1978. Fouling of the Skagit Wildlife Recreation Area would be considered critical to the wildlife and indirectly to consumptive and nonconsumptive recreational uses.

## Social and Economic Conditions

### Population

The three counties along the alternate segment had a 1975 population of 84,800 persons and are projected to have a population of 100,800 persons in 1980. Their projected average annual growth rate until the year 2005 is 2.0 percent. Island County, with the smallest land area, has the second largest population and is the fastest growing of these three counties (estimated 6.6 percent between 1975 and 1980).

The work force required for construction and operation of the alternate pipeline segment would be essentially the same as that required for the proposed route. Clallam County could experience a maximum influx of 982 nonlocal construction-associated people (including the construction force needed for the port). Island and Jefferson Counties could have a similar transient population influx of 811 construction-related persons. This impact would be of a temporary, short-term nature.

Potential impacts on population, housing, and community services would be greatest during the summer tourist season. Community facilities and services in Island County might be strained.

### Housing

During peak construction periods (approximately 1.5 months) Clallam, Island, and, to a lesser extent, Jefferson Counties would experience pressure on available housing. During the summer tourist season, availability of rental units could be strained, particularly in Oak Harbor on Whidbey Island. Impacts on housing during the operational phase should not be significant.

### Community Services

The impacts on community services (e.g. schools, fire and police protection, and medical services) would be similar to those described for the proposed route.

### Employment

Employment generated by the alternative in Clallam and Island Counties would be similar to the proposed route; however, less employment would be generated in Jefferson County.

### Taxes

During the construction period, tax revenues would accrue to state and local governments through the imposition of three major taxes: the leasehold excise tax, the sales tax, and the ad valorem property tax.

During construction of the submarine pipeline, payment of an annual leasehold excise tax would be made on all leases of public property (approximately 20 miles beneath the Strait of Juan de Fuca and Saratoga Passage). Estimates of probable revenue to be generated by the alternative route segment would not be available until a contract rent is established for leasing of the submarine pipeline route.

Sales tax revenues were based on construction costs and apportioned according to the length of pipeline and pump stations located within each county. Total sales tax revenues generated by the alternate segment would be $2,135,100; county revenues would be $209,400; and state revenues would be $1,925,700.

The submarine segments of the pipeline would not be subject to property tax (ad valorem).

## AROUND PUGET SOUND

A route around Puget Sound could be considered an alternative for the proposed TMC route across Puget Sound joining the proposed route near Stanwood, Washington. This alternative route would have a total mileage of 225 compared to 38 for the proposed route. Although this alternative may have more environmental disadvantages than the Cross Puget Sound proposal, future decisions by the State of Washington may eliminate considerations of any pipeline route across Puget Sound. Therefore, this possible legal constraint warrants consideration of an Around Puget Sound Alternative for the proposed pipeline system.

The Around Puget Sound Alternative for TMC would leave the proposed route at pipeline mile 47, near Fairmont, Washington and continue around Puget Sound to North Bend, Washington. This section was described in Chapter 9 for the Around Puget Sound Alternative considered for the NTPC System.

The route would then continue north to Stanwood, Washington rejoining the TMC proposed route at pipeline mile 85. This section was described for the NTPC System (between NTPC proposed pipeline mile 54 and 128) in Chapter 1.

The TMC Around Puget Sound Alternative would potentally have more environmental impacts than the proposed route across Puget Sound due primarily to the greater distance, 187 miles.

Construction impacts on air, land, and water resources would be greater. Operational impacts for oil spill risk would be greater due to the additional 187 pipeline miles. Overall environmental impacts would therefore be far greater for the Around Puget Sound Alternative.

Detailed environmental impacts for the Around Puget Sound segment from Green Point to North Bend were presented in chapter 9 for the NTPC System. From North Bend to

North Bend to Stanwood, environmental impacts were discussed in Chapter 3 under the NTPC System for pipeline miles 54 to 128. For comparison of the alternative impacts to the TMC proposed route, refer to the TMC analysis presented in Chapter 8 for proposed pipeline mile 47 to 85.

## 9.8 Other Crude Oil Transportation Systems

### LONG BEACH, CALIFORNIA, TO MIDLAND, TEXAS, AND MIDWEST (SOHIO)

SOHIO Transportation Company of California is sponsoring a combination of existing natural gas pipeline conversion and new pipeline construction from a new tanker terminal at Long Beach, California, to Midland, Texas, (1,027 miles) as shown in figure 9.8-1. The system includes reversal and conversion of 790 miles of existing 26- and 30-inch natural gas pipeline, and construction of 34 miles of new 30-inch pipeline, 194 miles of new 42-inch pipeline, and 9 miles of new 48-inch pipeline. Oil would travel 2,046 miles by tanker from Valdez to Long Beach, then through 790 miles of converted existing pipeline and 237 miles of new pipeline to Midland, Texas. Initial operational capacity would be 600,000 barrels per day, with eventual capacity of 1 million barrels per day. Sponsors predict that initial phase operation could begin 18 months after permits were issued. Estimated construction cost is $472 million. The Department of the Interior has approved the permit for crossing Federal lands. SOHIO was seeking approval for state permits when, on March 13,1979, the company announced abandonment of the project primarily due to economics and a decreased West Coast oil surplus. On June 20, 1979 SOHIO withdrew the right-of-way application filed under Title I, Mineral Leasing Act, with the Bureau of Land Management Department of the Interior.

The description and environmental analysis of the SOHIO port and pipeline system was presented in the Final Environmental Statement prepared by the BLM, U.S. Department of the Interior, in 1977.

### TRANS-MEXICO PIPELINE

Barber Oil Company proposed the Trans Mexico Pipeline (DOE Hearings July 1978) to transport Alaskan crude oil to U.S. Gulf or East Coast ports via a pipeline across the Isthmus of Mexico. The Alaska crude oil would be shipped by tanker from Valdez, Alaska to Salina Cruz, Mexico, off-loaded at the terminal, transported by pipeline across Mexico to Coatzacoalcos and then loaded on tankers bound for U.S. ports on the coast of the Gulf of Mexico and the eastern seaboard (figure 9.8-1).

The company proposes to construct a terminal at Salina Cruz, Mexico, that would have a total capacity of 1,750,000 barrels per day. The storage facility would have 30 days of storage, or 52.5 million barrels of oil.

The Pacific Ocean terminal would have one single point mooring, located 20 miles offshore and capable of off-loading one 400,000 dead weight ton tanker. The Gulf Coast side terminal would have 7 or 8 single point moorings located 4 miles offshore and capable of loading tankers in the 60,000 to 80,000 dead weight ton class.

A 36-inch to 48-inch pipeline with a design throughput of 1,750,000 barrels per day would be constructed across the Isthmus of Mexico for a distance of 165 miles. Another terminal and tank farm constructed at the pipeline terminus in Coatzacoalcos would also have 30 days' storage capacity.

A pump station would be located at the Pacific Ocean terminal and also at the Gulf of Mexico side. Three more pump stations would be located on the pipeline. All pump stations would be operated by diesel fuel which would be trucked to the sites.

Estimated construction cost is $700 million. Overall transportation costs from Valdez, via the Trans-Mexico pipeline to Houston, Texas was estimated at $1.65 per barrel of crude oil. The present status of this proposal is considered to be in the formative stages pending a more detailed feasibility study. The Mexican Government has been contacted but has not made any committment to approval of the project. However, Mexico would require 60 percent ownership of the project, which would eliminate United States control.

The marine environment on the pacific coast would be affected by the construction of a single point mooring and 20 miles of submarine pipeline to shore near Salina Cruz. Construction impacts would be short term. Chronic oil spills or leaks or ruptures of the line during operation could have long-term effects on marine resources.

Storage terminals for 52.5 million barrels at each end of the pipeline and five pump stations would change the use of an unspecified amount of terrain.

The 165 mile pipeline would pass between two mountain ranges, the Sierra Madre del Sur and the Sierra Madre, and would probably not have to rise more than 600 feet above sea level except for one short stretch that might go to 1,000 feet. Details of the route are not known but hazards and impact of mountainous terrain would be minimized.

Construction of seven or eight single point moorings, 4 miles offshore in the Gulf of Mexico and their connecting lines would have short-term impacts on the marine resources of that sea. Under operation chronic oil spills could have a long-term degrading affect on water quality and productivity. Pipeline leaks or ruptures could seriously impact this part of the Gulf. Under operation chronic oil spills could have a long-term degrading effect on water quality and productivity. Pipeline leaks or ruptures could seriously impact this part of the Gulf.

Lack of data precludes a detailed analysis of the environmental impacts of this proposal. EO 12114 did not extend NEPA's application for actions solely within a foreign country. The order does not affect NEPA requirements for proposals or portions of proposals within the United States. Thus, this proposal within Mexico has not been given an in-depth analysis. However, it has been briefly described to give the reader a full view of the alternative.

## TRANS-GUATEMALA PIPELINE (CAPICO)

Plans for the Trans-Guatemala pipeline proposed by the Central American Pipeline Company (CAPICO) were originally formed in 1974. CAPICO, is a Guernsey, Channel Islands, Corporation, which in turn owns 55 percent of the common stock of a Guatemalan Corporation, Intermares S.A. The remaining 45 percent of this company will be owned by Guatemalan interests, including possibly the Guatemalan government. CAPICO statements indicate that it has already been agreed in principle with the Guatemalan government that Intermares S.A. will have tax-free status and that the ports and pipeline corridor will be granted the status of an international free port. CAPICO also indicates that it has formed the Pacific and Atlantic Shipping Company with the express purpose of providing, together with the Intermares pipeline, an integrated service for Alaskan oil from Valdez to U. S. Gulf and East Coast markets (DOE 1979).

CAPICO has proposed a 42-inch, 227-mile pipeline from a new tanker terminal (up to 200,000 dead weight ton) at Buena Vista, Guatemala, to a new tanker terminal (up to 100,000 dead weight ton) at Puerto Barrios, Guatemala, where crude would be loaded into tankers for transshipment to Gulf Coast ports (figure 9.8-1). Oil would travel by tanker 4,125 miles from Valdez to Buena Vista, 227 miles through the new pipeline, and 1,067 miles by tanker to the Gulf Coast (Houston) and then utilize the mid-continent pipeline system for distribution to the Northern Tier states. Initial operational capacity would be 600,000 barrels per day with about 2 years construction time. Eventual capacity would reach 1.5 million barrels per day. Estimated construction cost is $600 million.

The pipeline would carry not only Alaska North Slope crude, but also foreign crudes to the United States Gulf Coast and the Caribbean. Jones Act vessels would be required to move Alaskan crude via this pipeline. However, since the export of Alaskan crude oil, is currently not permitted, the project would require a designation of "Fee Port" status. U.S. Federal Government approval is not required for the construction of the project but financing might prove difficult unless firm commitments could be obtained from U.S. companies willing and able to use the line for Alaskan crude oil.

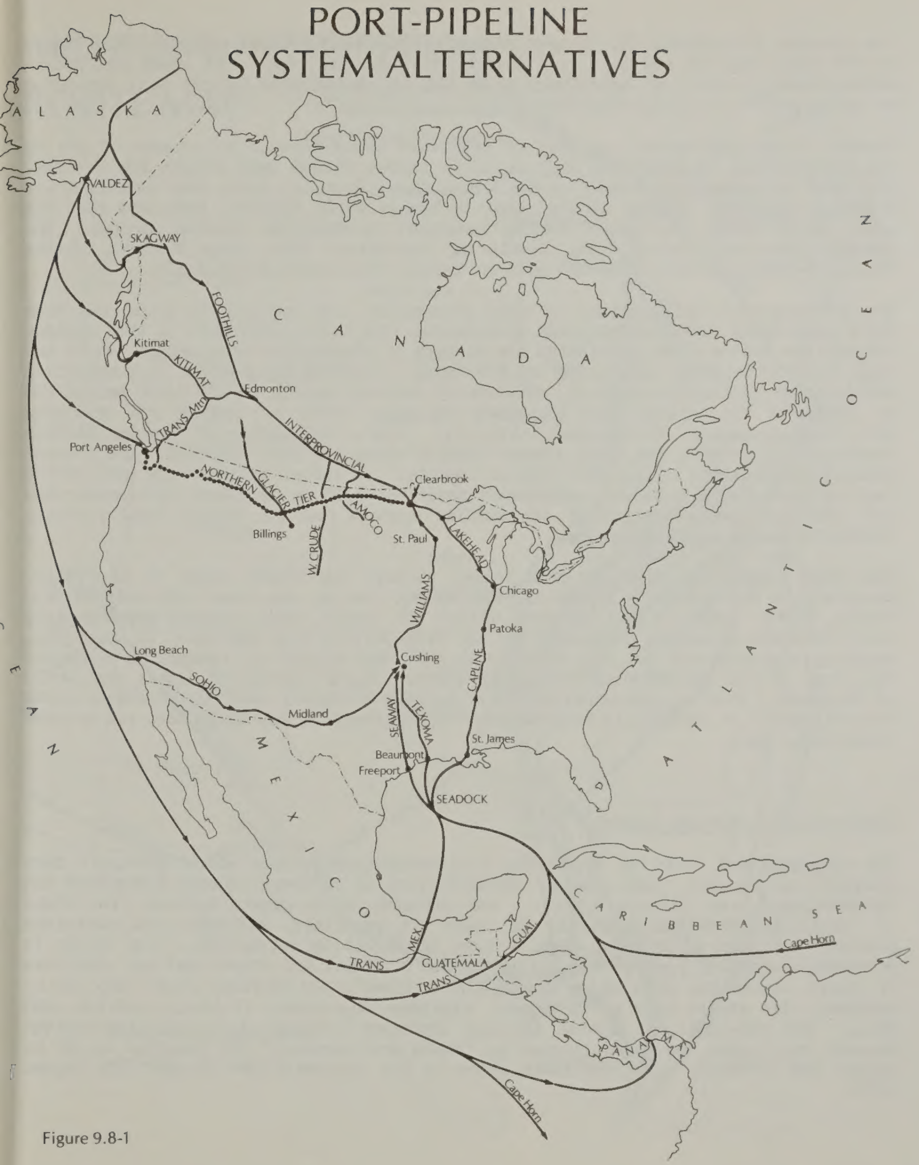
The Trans-Guatemalan Project involves the construction of two fixed berth facilities capable of servicing 200,000 dwt tankers at the unloading port, located at the entry point to the Canal de Chiquimulilla loading port, consisting of four fixed berths, capable of servicing 100,000 dwt tankers is proposed on the Caribbean Coast at Punta de Manibique. Both harbors would be manmade and dredged to 62 and 55 feet, respectively. Both would be furnished with supplementary dry cargo handling piers for construction and logistics purposes.

The system is designed for an initial throughput of 600,000 barrels per day, increasing to 900,000 barrels per day and ultimately to 1,200,000 barrels per day in the following 2 years. Maximum throughput would be 1,500,000 barrels per day after the final incremental investment.

Fixed-berth ports are needed because of the lack of protected waters for SPMs on the Pacific Coast and by the long distance to deep-water suitable for SPM on the Caribbean side. However, fixed berths require significant dredging, estimated at 25 percent of the combined costs of the terminals and storage. The 100,000 dwt tanker limitation on the Caribbean side appears an unnecessary limitation in view of the prospect that superports such as LOOP or Seadock might be built on the U.S. Gulf Coast.

A Pacific tank farm consisting of four tanks with 5 million barrels total capacity would be located about 1 mile from the Pacific port and a six-tank Caribbean tank farm with 7.5-million-barrel capacity would be sited about 1 mile inland from the Caribbean berths. A 250,000-barrel dirty ballast water tank and associated ballast-treating equipment would be located at the Caribbean terminal.

The proposed pipeline route starts at Buena Vista, near the Guatemala-ElSalvador border and ends in the Golfo de Honduras in the Caribbean, a distance of 227 miles (figure 9.8-1). A 42-inch pipeline is proposed, with 70,000 total installed horsepower to transport 1,200,000 barrels per day. There is some indication that by adding more pumping capacity and some looping, the line's throughput could be increased to 1,500,000 barrels per day although no detailed estimates are available regarding this potential expansion. A detailed route for the line has not been



PORT-PIPELINE SYSTEM ALTERNATIVES

Figure 9.8-1

selected, but a preliminary pipeline profile prepared by J. G. Mackin and Associates was used to design the required pumping stations and for estimating pipeline capital and operating costs. It appears that the proposed pipeline route would traverse some rather severe mountainous terrain for the first 85 miles and would then traverse level swampy terrain.

The entire project would take 24 months to complete, once all permits and authorizations are received. The system could be operational at half throughput (600MB/D) 18 months after initial construction work is completed. An early 1979 construction start was planned.

The Trans Guatemala proposal would result in environmental impacts on the marine environment and on the terrestrial environment across Guatemala. The potential for oil spills would exist for the marine sea leg from Valdez, Alaska to the terminal at Buena Vista, and from the Puerto Barrios terminal to the Gulf Coast ports. Construction of the 227-mile pipeline across Guatemala would cause short-term impacts on the terrestrial environment, such as vegetation and soils. The long-term impact would be the 227 miles of new utility corridor incluing 100 miles through mountainous areas and across four major rivers. Additional land would be required for the off-loading terminals and the onshore storage facilities. The potential for oil spills during operation would exist for the entire pipeline and also at the onshore storage facilities.

The potential advatages of this project aree as follows:

Would be the least expensive pipeline alternative for delivering ANS crude from the west to east coasts

Would poses no problem for conventional pipeline construction because the proposed pipeline route extends over relatively flat Guatemalan terrain.

Potential disadvantages of the project are as follows:

Would not be a U.S.-controlled pipeline,

Would have to rely on the midcontinent system to supply crude to the Chicago area,

Would not directly insure distribution of ANS crude to the northern tier states west of Minnesota, or solve predicted petroleum shortfalls in that area

Would require a longer distance for marine transport of ANS crude, increasing environmental hazards and security risks.

Further detailed environmental analysis was not conducted. EO 12114 did not extend NEPA's application extraterritorially for actions solely within a foreign country. The order does not affect NEPA requirements for proposals or portions of proposals within the United States. Thus, this proposal within Guatamala has not been given an in-depth analysis. However, it has been briefly described to give the reader a full view of the alternative.

## PANAMA CANAL AND MID-CONTINENT PIPELINES

Alternate supply sytems for transporting surplus West Coast crude oil could be by tanker around Cape Horn or through the Panama Canal to Gulf Coast ports. Both tanker systems would require utilizing the Mid-Continent Pipelines for distribution to refineries needing the crude oil supply.

### Shipment Around Cape Horn to the Gulf Coast

The largest vessels currently being built in U.S. shipyards are in the range of 200,000 to 390,000 dead weight ton. Assuming that U.S. flag carriers of 220,000 dead weight ton would be utilized in the marine movement from Valdez to the Gulf Coast, no 220,000 to 390,000 dead weight ton tankers exist for the Jones Act fleet.

Use of larger vessels would result in fewer tanker trips and in fewer loading and unloading operations at west coast terminals. To the extent that the possibility of spillage increases with the number of trips involved and that most chronic oil spills are associated with loading and unloading operations, the use of the larger vessels would perhaps give a slightly improved level of safety impact by reducing exposure to such risks. However, the weather and rough water associated with the passage around Cape Horn is substantially more hazardous than the weather conditions which prevail between Alaska and California, and to this extent, environmental debits accrue to the Sea Leg around Cape Horn in terms of risk of major oil spill. Furthermore, no facility currently exists on the Gulf Coast for accommodating vessels of the 220,000 dead weight ton class. One U.S. deepwater port facility project offshore of the Gulf Coast, LOOP, has been approved. While now under construction, the facilities to handle 220,000 dead weight ton tankers might be available by early 1981. At the present time, foreign flag tankers of this size are delivering their oil to Caribbean transshipment terminals such as Freeport at Curacao, West Indies for subsequent transfer to smaller vessels which can be accommodated in U.S. Gulf of Mexico coastal ports. Controlling depths along the Gulf Coast vary from 35 to 45 feet. Transshipment would require double handling of the oil, creating additional opportunities for chronic oil spills with resulting adverse environmental impacts.

The total round-trip distance from Valdez to the Gulf Coast via Cape Horn is approximately 31,000 nautical miles. During such a voyage, a 220,000 dead weight ton (or larger tanker available that could be loaded at Valdez) tanker would consume about 90,000 barrels of bunker fuel, or about 0.065 barrels of bunker fuel per barrel of crude oil delivered.

### Shipment through the Panama Canal to U.S. Gulf of Mexico Coast

The Maritime Administration, in a study commissioned by the Department of Energy, has determined that the existing and anticipated Jones Act fleet would be adequate to handle the full west coast surplus should the Panama Canal route and lightering be used. Lightering would allow 80,000 to 250,000 dead weight ton tankers to be used from Valdez to Panama and off-loaded at the Panama Canal to the 65,000 dead weight ton tankers able to transit the canal and off-load in Gulf Coast ports (SOHIO 1977).

The physical limitations for vessels transiting the Panama Canal are a maximum length of 960 feet, beam of 106 feet, and drafts of 37 to 39.5 feet. The canal can accommodate laden vessels of approximately 65,000 to 89,000 dead weight ton, depending on the vessel's particular dimensions.

Transit of 500,000 barrels per day of crude oil would require an average of one to two Panama Canal transits per day of fully loaded 65,000 dead weight ton vessels. The above information provided by the Panama Canal Company, which also expressed its desire to increase ability of the canal to handle world traffic, indicates that the canal could handle the tanker traffic necessary to move the Alaskan surplus. The company indicated further that lightering operations from large tankers of the Valdez-to-Panama route to tankers able to transit the canal are feasible.

The environmental implications of this alternative are not greatly different from those associated with the Cape Horn alternative. The major difference is that passage through the Panama Canal eliminates the dangers of stormy Cape Horn waters, while the Cape route eliminates lightering at the canal. Lightering results in substantial emissions of hydrocarbon vapors. The use of smaller vessels (65,000 dead weight ton or less) for the entire route increases the total number of loading and unloading operations necessary to transport this oil. Also, utilization of smaller tankers results in increasing the total tanker traffic along the west coast with the corresponding implications of greater risks of spills. If larger vessels were used on the Pacific side of the movement, additional handling would be necessary to transfer the oil from the larger vessels to the smaller vessels for the Panama Canal passage. Chronic spillage would be greater.

The total round-trip distance from Valdez through the Panama Canal to St. James, Louisiana is approximately 17,000 nautical miles. During the round trip portion from Valdez to the Canal, a 165,000 dead weight ton tanker would consume approximately 27,950 barrels of bunker fuel. During the trip portion from the Canal to Louisiana, assuming approximately two and one-half 65,000 dead weight ton tankers to transport the cargo of the 165,000 dead weight ton tanker, 15,840 barrels of bunker fuel would be consumed. This is approximately 0.037 barrels of bunker fuel per barrel of crude oil delivered, or about half that demanded by delivery to the Gulf Coast via a route around Cape Horn.

### Mid-Continent Pipeline System

The Mid-Continent Pipeline System is a network of pipelines which transport both domestic and foreign crude oils to redistribution or refinery centers throughout the Mid-Continent area (figure 9.8-2). The network, which generally runs from south to north, is comprised primarily of crude oil pipelines, although some petroleum product lines are also being used to move crude oil to refineries. The system is presently supplying much of the northern tier's demand for crude, and new pipelines or future expansions of existing Mid-Continent lines could increase crude supplies to northern tier states such as Minnesota, Michigan, Wisconsin, Illinois, Indiana, and Ohio. The Mid-Continent System is also important because crude oils transported through the system can be delivered to Canada and exchanged for Canadian crude to supply the needs of crude deficient areas in the Northern Tier states (DOE August 1978).

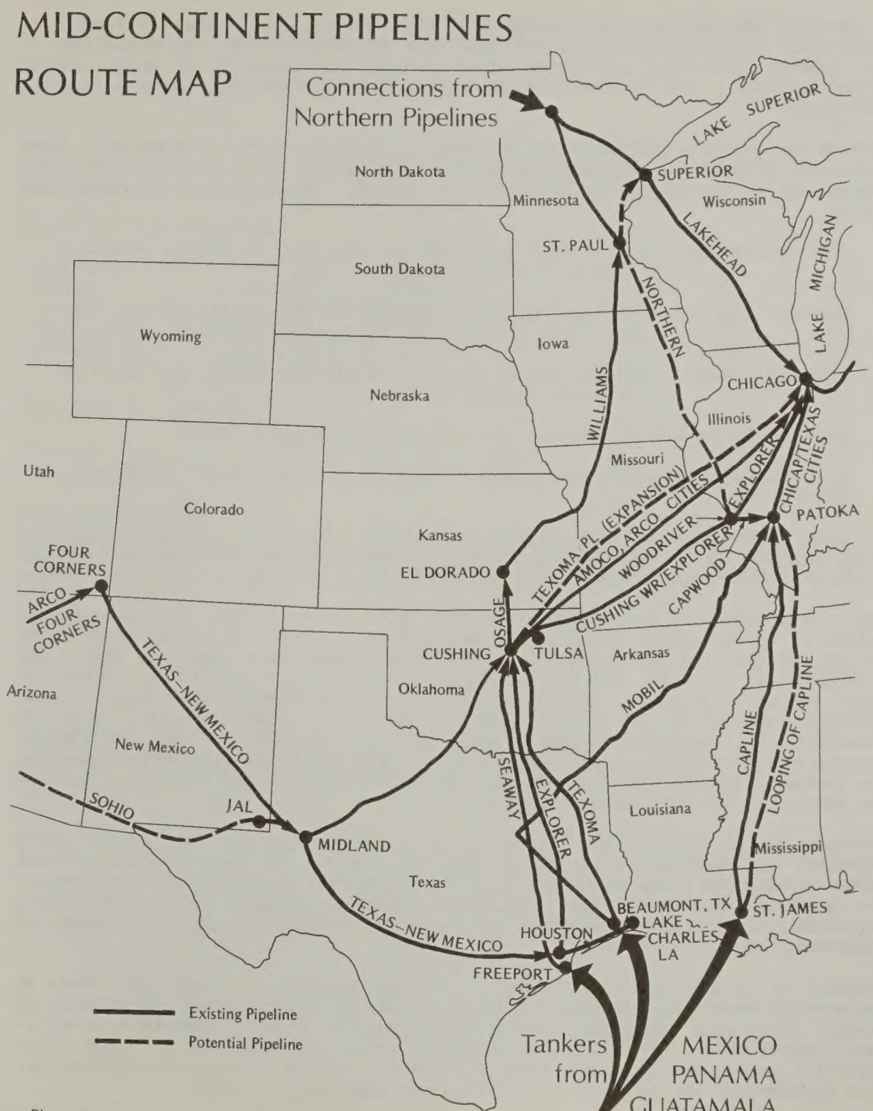


Figure 9.8-2

The existing Mid-Continent Pipeline System is separated into three parts, based on pipeline origins: 1) the Gulf Coast; 2) Patoka, Illinois; 3) and Cushing, Oklahoma. These are the three most critical areas in terms of analyzing crude capacities and identifying system deficiencies.

There are two main pipelines which exit the Patoka, Illinois, area. These are the Chicap and the Texaco Cities lines, both of which are currently operating at capacity.

The Chicap Pipeline is 203 miles of 26-inch line, plus 32 miles of another line, which extends from Patoka, Illinois, to the Chicago area. The 382,000 barrels per day line, now operating at capacity, receives crude from the Mobil and Capline Pipelines, and supplies crude to the Chicago refineries. The Chicap Pipeline expanded capacity to about 490,000 barrels per day, in September 1978.

The Texaco Cities Pipeline is an 18-inch line which extends from Patoka to Chicago. The line has a 153,000 barrels per day capacity and is operating at capacity. Expansion of the system's capacity is constrained by three factors: 1) capacities of installed pumps and pressure limitations, 2) supply constraints of the lack of crude oil from other interconnecting pipelines, and 3) delivery constraints because of upstream pipeline restrictions.

There are four main pipelines which exit Cushing, Oklahoma, for regional demand centers. These are the Arco, Amoco, and Texas Cities Pipelines which extend to Chicago, and the Williams Pipeline which extends to Minneapolis. The following summarizes the crude potential for these systems.

The Amoco Pipeline System is a common carrier serving the Mid-Continent area, which extends from the Rocky Mountains, west Texas, and the Gulf Coast to Kansas City, Chicago, and St. Louis. The main line serving the Mid-Continent area extends from Cushing to Chicago, and is a continuation of an 8-inch; two, 12-inch; and a 20-inch line. The system has a 370,000 barrels per day capacity and is currently operating at about 300,000 barrels per day. Expansions to the system would involve looping which is currently not under consideration.

The Arco Pipeline is a 24- and 22-inch line which extends from Cushing to Key, Missouri, and to Chicago. The line has a 300,000 barrels per day capacity and it has been operating at this level since December 1976. The only expansion possibilities for this line are to loop the line and the economics for such a project are presently uncertain.

The Texaco Cities service crude pipelines interconnect with several lines to transport crude from Cushing, Oklahoma and Patoka, Illinois to the Chicago area. One, 8-inch and two, 12-inch lines run from Cushing to Chicago, and an 18-inch line extends from Patoka to Chicago. The line from Cushing to Chicago has 46,000 barrels per day capacity and the line is operating at that level.

The Williams Pipeline carries refined products from refineries in Oklahoma and Kansas to markets in Nebraska, Iowa, Illinois, Missouri, Indiana, South Dakota, North Dakota, Minnesota, and Wisconsin. The main trunklines run north from Barnsdall, Oklahoma through Kansas City and Des Moines to the Minneapolis-St. Paul area. The Williams Product Pipeline has, since 1974, delivered some crude to the Northern Tier area as spare capacity has become available. Initally, about 20,000 barrels per day of crude oil moved to the Minneapolis area, but recent expansions to the system in

1977 allowed about 80,000 barrels per day of crude to move to the area. A second expansion was completed in August 1978 and is transporting 120,000 barrels per day of crude to move to St. Paul, Minnesota.

Williams Pipeline Company is also considering further expansion to its main line system which could raise the crude oil capacity of 285,000 barrels per day to the Minneapolis area and 70,000 barrels per day to the Wrenshall-Superior area. This expansion would entail 691 miles of 24-inch line from Cushing to Mason City and 163 miles of 12-inch line from Cottage Grove to Wrenshall-Superior, plus pumps and tankage, and cost about $189 million.

There are five major pipeline systems which originate in the Gulf Coast and supply crude to the Mid-Continent area. These are the Explorer, Texoma, Mobil, Seaway, and Capline Pipelines. The following summarizes these systems and their potential for supplying crude to demand centers.

> Explorer Pipeline is a product line which batches crude to the Tulsa and Chicago areas from Lake Charles, Louisiana. The 90,000 barrels per day of crude capacity of system, has been increased to 145,000 barrels per day. The system is being expanded to provide a total of about 335,000 barrels per day to Tulsa and 235,000 B/D to Chicago.
>
> Texoma Pipeline is a 300,000 barrels per day line extending from Beaumont, Texas to Cushing, Oklahoma. The line is presently operating at capacity, but could be expanded to 620,000 barrels per day with increased demand. Presently, Amoco is considering a 200,000 to 600,000 barrels per day extension to the Texoma line from Cushing to Chicago. This extension would necessitate an increase in the Texoma line to its ultimate capacity.
>
> Mobil Pipeline is a 165,000 barrels per day line from Beaumont, Texas to Patoka, Illinois. The line is presently full and there are no plans to expand capacity.
>
> Seaway Pipeline is a 320,000 barrels per day line extending from Freeport, Texas to Cushing, Oklahoma. The system is currently operating at 240,000 barrels per day. Ultimate capacity of the system is 592,000 barrels per day.
>
> Capline Pipeline is a 1,160,000 barrels per day line extending from St.James, Louisiana to Patoka, Illinois. The system is currently operating at capacity and the only means of expansion is to loop the line. This is presently being considered and the segment between St. James to Patoka is concurrent with the first stage operation of the LOOP project which would transport 140,000 barrels per day when completed in 1980.

In summary, the Mid-Continent Pipeline System comprises many major crude oil pipelines. Currently, most existing pipelines are at or near capacity; increases in demand or cutbacks on other crude sources, such as Canadian curtailments, must be offset with increases in existing lines or with new lines. There is very little unused capacity on the existing system. The Seaway Pipeline shows 80,000 barrels per day of excess. There also appears some capacity on the Explorer Pipeline actual throughput volumes are 90,000 barrels per day, but they are expected to reach 145,000 barrels per day. However, crude capacity on the Explorer Pipeline is also dictated by product throughput which has priority over crude.

In general, the Mid-Continent System is full. However, the system is capable of significant expansion. Based on published data or comments from representatives of the various pipelines, the system could increase its capacity by about 875,000 barrels per day. Most of these increases, 530,000 barrels per day, would be from the Gulf Coast.

Several new pipeline proposals are currently in various states of planning. These proposals, if built, would materially affect the supply of crude to the Mid-Continent System and to several of the Northern Tier states. These systems are summarized below:

> Capline Looping---up to 1 million barrels per day from St. James, Louisiana to Patoka, Illinois.
>
> Northern Pipeline---175,000 barrels per day to 240,000 barrels per day from Wood River, Illinois to Minneapolis, Minnesota.
>
> Texoma Extension---200,000 barrels per day to 600,000 barrels per day from Cushing to Chicago, Illinois.
>
> SOHIO---500,000 barrels per day from Long Beach to Midland, Texas.
>
> Four Corners---up to 150,000 barrels per day from Long Beach to Houston, Texas.

As shown, five major new lines are being considered which would materially affect the crude supplies to the Mid-Continent area. A summary of the existing Mid-Continent Pipeline System capacity and potential expansion was presented in table 9.8-1.

There is presently no detailed environmental data concerning these Gulf Port combinations to use in making an environmental analysis. Crude oil is presently being shipped through the Canal, with the aid of a transshipment facility, and a new permanent port facility. All four of the proposals involve a much longer shipment by water therefore present a greater spill risk and fuel cost. The three Central American proposals involve four transfers in port. As a result of these additional transfers a corresponding increase in spill risk could be expected. The construction impacts of either of the two Central American pipelines would also include building new berths on both the Pacific side and the Gulf of Mexico side, submarine pipelines and storage on the West and East Coasts.

Expansion of the Mid-Continent network would require substantial new construction of pipelines and expansion of the port facilities. The new pipeline construction would occur in many populated areas and could be expected to cause moderate disruption. The existing United States port facilities already exceed most Federal air quality standards and additional through-put could be expected to exaggerate the existing situation.

Shipment to the gulf ports and through an expanded Mid-Continent pipeline network to the Northern Tier refineries would require substantial investment and coordination by several independent companies. If, in the judgment of pipeline investors, a sufficient demand exists and a profit could be expected on the operation of such a transportation system, new proposals would be expected. Pending these further proposals, this hypothetical new capacity cannot be further analyzed.

TABLE 9.8-1 SUMMARY OF EXISTING MIDCONTINENT PIPELINE CAPACITIES, THROUGHPUTS, AND POTENTIAL CAPACITIES (MB/D)

|  | From | To | Current Capacity | Current Throughput | Maximum Capacity | Potential Over Current Capacity |
|---|---|---|---|---|---|---|
| Pipelines from Gulf Coast |  |  |  |  |  |  |
| Capline 1/ | St James | Patoka | 1,160 | 1,160 | 1,160 | 0 |
| Texoma | Beaumont | Cushing | 300 | 300 | 620 | 320 |
| Mobil | Beaumont | Patoka | 165 | 165 | 165 | 0 |
| Seaway 1/2/ | Freeport | Cushing | 320 1/ | 240 | 592 | 272 |

Proposed New/Expanded Systems

Capline looping--up to an additional 1 MMB/D from St. James to Patoka
Northern Pipeline--175MB/D to 240 MB/D from Wood River to Minneapolis
Texoma Extension--200MB/D to 600 MB/D from Cushing to Chicago

Source: Department of Energy 1979

1/ Transshipment of ANS crude from Valdez by 65,000 dwt tanker through the Panama Canal and into gulf ports located in Texas and Louisiana. To accommodate tanker movement, two offshore deepwater crude terminals have been proposed at these ports--the Louisiana Offshore Oil Port (LOOP) would be located 19 miles south of Grand Isle, near St. James, LA., and would send oil through the Capline system, currently operating at full design capacity.

2/ Data effective August 1978.

3/ Data for Explorer is based on crude flows only. These cannot exceed 50 percent of the throughput. Actual capacities are twice values shown.

## NORTHVILLE PANAMA TRANSSHIPMENT

Northville Industries Corporation, Huntington Station, New York, presented a proposal for transshipment of Alaskan crude oil through the Panama Canal to the Gulf Coast. The system moves crude from the Valdez, Alaska pipeline terminus via tanker through a Panama Canal transshipment facility to Gulf and East Coast ports for ultimate distribution by pipeline to Northern Tier states (Northville Industries 1978).

The Panamania Transshipment Port (PTP), currently in operation at Puerto Armuelles, was completed in December 1978 and operational in 1979. The site was selected for its proximity to the Canal, deep water, sheltered harbor, and suitable topography for the combination of docking and terminaling components.

While construction was being completed, oil shipment through the Canal was being accomplished by lightering operations carried out through two supertankers anchored at the Gulf of Parita. This temporary operation effectively transshipped in excess of 400,000 barrels per day.

The PTP terminal receives large oil tankers from Valdez, off-loads to storage tanks and reloads oil onto shuttle tankers transiting the Panama Canal. Transshipments are economically possible because the largest tanker which can transit the Panama Canal is 67,500 dead weight ton. The transshipment facility permits shippers to gain the economies offered by supertanker transport (up to 265,000 dwt) as far as Panama's west coast.

The PTP terminal has an initial throughput capacity of 425,000 barrels per day and storage of 2.5 million barrels in three, 830,000 barrel tanks. Two ship berths were constructed with the following specifications:

|  | Berth One | Berth Two |
|---|---|---|
| Maximum size tanker | 265,000 dwt | 90,000 dwt |
| Minimum size tanker | 30,000 | 30,000 |
| Water depth at berth (mean low water) | 80 feet | 58 feet |
| Maximum off-loading rate | 100,000 BPH | 48,000 BPH |
| Maximum loading rate | 48,000 BPH | 48,000 BPH |

Complete ballast treatment/oil recovery systems are also included in the transshipment complex.

Present crude oil throughput for the facility is not known. The PTP facility could be expanded to accommodate future needs by the addition of necessary storage capacity and two more jetties. Such expansion would provide a throughput capacity of approximately 900,000 barrels per day.

Until the completion of the onshore transshipment terminal, surplus Alaska crude was being transshipped via lightering off the West Coast of Panama. Two, 265,000 dwt vessels owned by British Petroleum were employed as floating storage vessels in the lightering operation.

Industry sources estimate that each vessel was outfitted at a cost of $2 million and costs $30,000 per day to operate. Including positioning expenses and transshipment fees, lightering costs approximately $0.15 per barrel.

Industry sources indicate that lightering between a floating storage vessel and a shuttle cannot be carried out in seas greater than 6 to 8 feet or winds greater than 30 miles per hour. It is reported that these conditions require a shutdown in operations at least 1 day a month, and during harsher weather spells, shutdowns have been considerably longer. Transshipment operations at the onshore terminal would not be subject to such delays.

Operational difficulties impair the effectiveness of a lightering operation. Approximately 4.5 million barrels of dirty ballast discharged by shuttles into the floating storage vessels must be reloaded into vessels returning to Valdez where the ballast is treated. These two ballast transfers result in the loss of up to 3 days per month of docking time. Such an operation is unnecessary at the onshore terminal, which is equipped with ballast treatment facilities. In addition, greater time must be allocated to berthing vessels against the floating storage ships as opposed to permanent jetties situated in a sheltered harbor. Finally, jetty loading arms at the onshore terminal pump at higher rates than those of the floating storage vessel.

Industry sources indicate that at least 1 additional day is required for loading and discharging via lightering as opposed to onshore transshipment. Experience with lightering off the West Coast of Panama confirms this estimate. In the month of June, shuttles and VLCCs averaged 41 to 84 hours, respectively, from time of arrival at the lightering site to time of departure. With operation of the onshore terminal, vessels arriving on schedule are loaded and unloaded within 24 and 30 hours, respectively.

Following shipment to the Gulf Coast Ports, the Alaskan Crude oil would be distributed to some of the Northern Tier states through the Mid-Continent pipeline system. For capacity and distribution, refer to the previous section which describes the Mid-Continent Pipeline System.

## UNIT TRAINS

Unit train transport has been proposed as a short-term alternative to transport the surplus flow of North Slope crude oil and supply the refineries in Montana. The General American Transportation Company (GATX) and the Burlington Railroad proposed the Unit Train System in 1977. The U.S. Army Corps of Engineers, Portland, Oregon District prepared an Environmental Assessment in April,1978 and began preparation of an Environmental Statement. In September, 1978 GATX announced plans for abeyance of the project with the U.S. Army Corps of Engineers. Although the specific project is presently inactive, the Unit Train System will be considered as an alternative.

A unit train consists of about 90 oversize tank cars with a total capacity of 50,000 barrels per train. GATX and the Burlington Northern Railroad, have proposed to use Port Westward, Oregon, an 850-acre U.S. Army fuel depot, as western terminus for unit trains. The port can presently accommodate 30,000 to 35,000 dead weight ton tankers and unloading facilities can transfer about 35,000 barrels of oil per day. Dredging to accommodate larger tankers up to 75,000 dead weight ton and expansions of unloading facilities to transfer up to 48,000 barrels per day is proposed. Approximately two to five tankers would call at the port each month. Burlington Northern proposes to transport the crude oil by train primarily to markets in Montana.

Potential environmental impacts exists from the tanker shipment in the Columbia River, construction and operation of the Port Westward terminal and unit train shipment near sensitive area in Oregon, Washington, Idaho, and Montana. The Oregon Department of Environmental Quality (DEQ) and the U.S. Army Corps of Engineers (COE) have presented preliminary environmental assessments on the GATX proposal.

The tanker shipment of Alaska sour crude oil and some foreign sweet crude oil would increase the oil spill risk in the Columbia River up to Port Westward. The Oregon DEQ Staff Report (November 1977) stated that no significant oil spills would occur from the tank farm and rail car loading pad based upon the technology of oil spill prevention. Oil Spill risk from the tanker and the off-loading at the dock would be regulated by the U.S. Coast Guard and by the Federal SPCC (Spill Prevention Control and Containment) plan. Following review of the GATX application, the Oregon DEQ issued an Air Containment Discharge Permit (No. 05-2569) and a Water Pollution Control Facilities Permit with special conditions attached.

The Port of St. Helens' Draft Public Notice and application for upgrading the docking facilities at Port Westward prompted the U.S. Army Corps of Engineers to prepare a preliminary Environmental Assessment. The COE summarized the environmental impacts as follows:

a. The issuance of the permit would result in an increase in tanker traffic and a substantial increase in the volume of crude oil shipped on the Columbia River. The level predicted would likely increase both the risk of major spill occurring as well as its associated impacts. A detailed risk analysis should be performed to determine the probability of a major spill occurring on the Columbia River, both with and without the GATX terminal.

A sufficiently detailed analysis should be prepared to identify both environmental and socioeconomic impacts of oil spills of different magnitudes at high and low flow periods, during major fish-spawning and migration periods, and during maximum, waterfowl use periods. The assessment should be done, as a minimum, for the area around Port Westward, for the immediate Columbia River Estuary, and for the Columbia River Bar.

b. Transporting crude oil by rail from Port Westward to Pasco, Washington, would also increase the potential for a major oil spill in the river. The risk analysis should include the probability of a spill and potential impacts associated with transporting the oil by rail along the Columbia from Port Westward to Pasco. The risk analysis should address the increased frequency of rail traffic, conditions of the track, and past records of accidents on the line. The impact assessment should include the conditions discussed above, as well as the potential impacts to the fish facilities at the Columbia River Dams downstream from Pasco and should be done for at least four separate upper river areas.

c. Since the impact of a spill also depends upon the effectiveness of the containment and cleanup operations, an assessment should be made of the available methods and equipment for containment and cleanup, as well as their respective effectiveness and availability in the upper and lower Columbia River, the Columbia River Estuary and Bar.

d. The proposal's consistency with the goals and guidelines of the local and State Land-use plans will have to be evaluated, as well as the applicability of the recent amendments to the Marine Mammal Protection Act.

e. The project may create a significant noise impact at the terminal and along the spur line. This should be assessed by determining the increase in noise above the ambient levels for noise-sensitive areas (residential areas, hospitals, schools, rest homes, etc.) along the spur line and near the terminal.

f. Though it would appear that the project will have little socioeconomic impact to the local or regional area, assessment would be necessary to confirm this. The assessment should include the potential impacts of using the facility for storage and transfer of locally used petroleum products.

g. An assessment of alternatives would be required in order to determine if the proposed action is the most desirable from an economic, environmental, and public interest standpoint.

## 9.9 Other Alternatives

A number of other alternatives have been considered by the Environmental Statement team and were raised by the public during the comment period. They include such alternatives as the following: Conservation, exchanges with Japan or Canada, retrofitting refineries, reducing Alaskan production, redistribution or, reallocation of domestic supplies, and arctic seatrains. Detailed environmental impact analysis for each of these alternatives would be inappropriate in the absence of specific proposals which would be subject to such an analysis. For example, conservation is a most important national goal, but it is a goal that is vague, has almost unlimited methods of being accomplished, and is nationwide in scope. To attempt to consider in detail the environmental impacts nationwide of an almost infinite number of combinations to reach an undefined goal has not been attempted. Another example: A swap of Alaskan oil, With whom? From what part of the world would the oil be shipped to replace the Alaskan oil sold to Japan? Again, it is believed not only unnecessary, but also impossible within the context of this ES to consider world-wide shipping of oil. When any of these currently broad concepts are reduced to specific proposals, they would, at that time, be subject to the provisions of NEPA.

Each of these altenatives have been outlined in the following discussion to present a general discusion of each to the public and the decisionmaker.

There are several alternatives not requiring a new west to east pipeline that would reduce or negate the need of the proposed projects. Although, individually they don't accomplish the purpose of the proposed projects, arranged in different combinations and proportions they could provide an almost unlimited number of actions that together would accomplish much of the same purpose. These can be discussed in three major categories: Those that reduce the surplus on the west coast, those that would supply crude oil to the northern tier states, and those that would reduce the projected demand for crude oil in the northern tier states.

### Reduce West Coast Surplus

Of the 1.2 million bpd that was being delivered by Trans Alaskan Pipeline (TAPS) in May 1979, 440,000 bpd was surplus to the demand on the west coast and was shipped to the Gulf Coast. 400,000 bpd a day was shipped through the Panama Canal and 40,000 bpd was shipped around Cape Horn. The TAPS line is scheduled to be increased to 1.35 million bpd in January 1980 and has an ultimate capacity with additional pump stations of two million bpd.

It should be understood that the surplus of heavy crude on the west coast is only surplus or in excess of the refinery preference for the type of crude they wish to process. This preference is determined by the design of the refinery and the demand for the mix of refined products in the area, the lighter the crude oil the higher the yield of gasoline. Because of this refinery preference large amounts of light foreign crude are imported into the west coast.

Retrofitting of existing refineries to process heavier crudes or the construction of new refineries is an extremely expensive undertaking, but conversions could be done and this is an action that would reduce the excess of heavy crudes on the west coast. Conversion could be voluntary or there could be some form of governmental stimulation. Voluntary conversion would be expected to occur when economic factors would favor such an action, such as ANS crude being priced to make it attractive in relation to foreign crude, or if foreign crude was not available. Governmental action, could stimulate conversion by methods such as tax credits, loan subsidies similar to the present Entitlements Program, or by placing a duty on foreign crude.

Exchange of ANS for foreign crude that could be delivered to U.S. ports more economically has been proposed by the state of Alaska and others. This is prohibited by the Alaska Pipeline Act (Public Law 93-153) unless the President determines that it will not diminish the quantity or quality of the petroleum available to the U.S. and is otherwise in the national interest. The President's decision to approve an export after making these determinations is subject to veto by Congress within 60 days after his decision. The state of Alaska proposal would involve the exchange of ANS crude with Mexico. The ANS crude would be shipped to Japan and the Mexican crude would be delivered to Gulf Coast ports. The shipping cost would be reduced because of the short distance from the west coast of Mexico to the Gulf ports and the economy of using large tankers for shipment from Valdez to Japan.

Any action that reduces the transportation costs on ANS crude, such as full utilization on the west coast or foreign exchange, would increase the profits to the owners of the oil and also the royalties to the state of Alaska. This could increase the incentive to the oil companies for further exploration and production in Alaska and could serve to reduce the U.S. dependence on foreign crude.

One method of eliminating the west coast surplus would be to reduce the production of ANS crude to the level of west coast demand. While this reduces the transportation costs and provides the lowest cost storage it would increase the U.S. dependence on foreign crude, adversely affect the balance of payments, reduce income to the state of Alaska and the owners of the oil and the pipeline. Presently almost all of the west coast surplus is being shipped through the Panama Canal or around Cape Horn. While there is a limit to the number of ships that can use the canal, there is no limit to the number of ships that can go around Cape Horn. The Cape Horn transit is limited due to the lack of deep water ports in the Gulf, which requires the use of small tankers or a lightering operation in the Gulf. Because of the higher transportation cost this is one of the least attractive options for the owners of the oil and the state of Alaska. A small portion of the surplus is being transported to Long Beach by the ARCO Company and through the recently reversed 16 inch Four Corners Pipeline to Red Messa, Utah. With additional pump stations the throughput of this line can be increased to 150,000 bpd. By connection to the nearby 16-inch Texas-New Mexico Pipeline, oil can be moved to Midland, Texas to connect with other pipelines that serve refineries in the southwest and east.

## Other Sources of Supply

There are several other actions or combination of events that would supply the northern tier states with additional crude oil to meet the transportation deficit that is projected. It is possible the Canadian Government could change or modify its plans to curtail exports of crude oil to the United States by 1982. There is no indication that this is going to happen, but if it did that would relieve all or much of the projected deficit. Additional imports from any country would be counter to this country's policy of energy independence and would adversely affect the balance of payments. There is presently some crude oil being exchanged by some U.S. refineries for Canadian crude. New exchange agreements could be negotiated that would increase supply in some of the Northern Tier states, but without construction of new ports or pipelines there is limited opportunity for such exchanges.

There is not believed to be substantial new opportunities for crude oil discoveries in the northern tier area. If the price of oil continues to increase, oil shale and more expensive secondary and tertiary recovery methods may be financially feasible. If new discoveries are made they would provide an alternative to the proposed project. It is also possible to change the existing transportation patterns in the Mid-Continent area to supply different refineries. Redirection of crude supplies would relieve individual refinery deficits, but because there is little idle capacity in Mid-Continent pipelines, redirection only serves to redistribute the deficit unless new pipelines are constructed. New pipelines from the Gulf ports would relieve a large amount of the transportation deficit and supply refineries in many, but not all, of the Northern Tier states.

Unit trains have also been proposed to connect to the Continental Pipeline at Cutbank, Montana to supply the Billings areas refineries. The proponent General American Transportation Corporation does not see this proposal as an alternative to a major west to east pipeline, but rather as a short term alternative for the Montana refineries. The tariff to Billings is projected at $2.24 per barrel from Port Westward on the lower Columbia River in Oregon to Billings, Montana. Unit trains to serve refineries further east would be less feasible as the rail cost is expected to be approximately two thirds of the total tariff.

## Reduced Demand

A final series of actions or events that would reduce the need for the proposed projects would be to reduce the demand for crude oil in the northern tier states. Further conservation of petroleum products would reduce demand. It must be understood that in all of the projections for demand, conservation has been taken into account. The accuracy of these projections is dependent on the validity of the assumptions that were used in determining them. For example, the projections for nuclear capacity installations were made prior to the accident at Three Mile Island, and any reduction or delay in nuclear installations could increase projected demand for petroleum products. If there is additional conservation beyond the amount projected in the different demand models, then the crude oil deficit is correspondingly reduced. Conversely, if conservation has been over projected then there is a greater deficit. It is difficult to discuss increased voluntary conservation without knowing the projected levels of conservation in the different models. Factors that could induce additional voluntary conservation would include; 1) increase of the conservation ethic among citizens for the nations and future generations benefit, 2) reduction of the supply of products to force conservation by inconvenience or denying access by the supplier, 3) increased conservation as a result of a higher price on the products, 4) mandatory conservation by government action. There is presently no evidence that demand for petroleum products is influenced in the U.S. by price. It is hypothesied that at a greatly increased price that there would be some conservation, but this remains unproven and would have to be a higher price then was assumed in the demand projections.

It is also possible for governmental actions to stimulate conservation, the opportunities range from a policy of not repairing or improving the highways system to the subsidy of mass transit to conserve gasoline. The National Energy Conservation Policy Act of 1978 provides 1) Utility Conservation Program for residences, 2)

Weatherization grants for low income families, 3) Solar energy loan programs, 4) Energy Conservation loan programs, 5) Grant programs for schools and hospitals, 6) Energy audits for public buildings, 7) Appliance efficiency standards, and 8) Civil penalties relating to automobile fuel efficiency. These types of programs can be increased or expanded to encourage conservation. To the extent that these types of actions are more successful than the assumptions in the demand projection, the projected deficit would be reduced. Finally, mandatory government controls such as rationing, or prohibiting the use of petroleum for certain purposes would reduce the projected deficit. The Powerplant and Industrial Fuel Act of 1976 prohibits the use of oil or natural gas in large new electric utility generation facilities or in large new industrial boilers and limits the use of natural gas of existing utility power plants. Similar legislation affecting the uses of other petroleum products could also conserve and reduce demand.

Importing petroleum products into the northern tier states would reduce demand for crude oil in these states but without state refineries and product pipelines and it would only relocate the projected deficit. In combination with other actions discussed previously, it could serve as a tool to relieve specific geographical shortages.

The substitution of other energy sources for petroleum products would also reduce the projected deficit. This could be encouraged by governmental action or could occur voluntarily because of a price imbalance between sources of energy.

None of the foregoing actions by themselves will eliminate the need for the proposed projects. A series of actions could serve to reduce the surplus of heavy crude on the west coast, supply crude oil to the Northern Tier refineries, or reduce the demand for crude oil in these states. There are unlimited combinations of the above actions, that could change the projected need for the proposals.

## 10.1 Introduction and Organization

The Bureau of Land Management (BLM) has consulted with federal, state, and local agencies as well as private companies and individuals concerning the development of this Environmental Statement (ES). Consultation with governmental agencies helped to insure proper coverage of all topical areas in the Environmental Statement and to minimize duplication of work. Public comment and participation was encouraged in the early development of the ES, prior to the completion of the draft ES (DES).

### Summary of Events Pertaining to the Preparation of the Environmental Statement

| | |
|---|---|
| 12-14-76 | Representatives of Northern Tier Pipeline Company (NTPC) met with the Department of the Interior (DOI) and other federal agencies to describe their proposal. |
| 02-22-77 | The Assistant Secretary, Land and Water Resources, DOI, sent a letter to NTPC outlining the requirements of the Mineral Leasing Act (pertaining to right-of-way requirements on federal lands) and of the need for an environmental statement. |
| 04-18-77 | NTPC filed a right-of-way application with the BLM, Montana State Director. |
| 01-19-78 | NTPC met with the Interagency Coordination Committee to describe its crude oil transportation proposal and to answer questions. |
| 02-08-78 | NTPC transmitted its Description of the Proposed Action (DPA) to the environmental statement team. |
| 03-08-78 | BLM began its first series of public information meetings. |
| 04-24-78 | Notice from NTPC of major changes in the proposed pipeline route in Idaho, Montana, North Dakota, and Minnesota. |
| 05-15-78 | The Interagency Coordination Committee met to discuss changes in the DPA, agency concerns, technical assistance, and schedule revision. |
| 06-06-78 | The Bureau of Indian Affairs advised BLM that the Tribal Council of the Confederated Salish and Kootenai Tribes refused NTPC permission to route the pipeline through the Flathead Indian Reservation. |
| 08-01-78 | NTPC amended the route designation and identified alternative route segments. |
| 08-01-78 | BLM began its second series of public information meetings. |
| 10-24-78 | NTPC notified the BLM of an additional route change (to be integrated into the FES). |
| 10-31-78 | The Interagency Coordination Committee met to discuss the preliminary draft ES and review comments. |
| 11-09-78 | Public Utility Regulatory Policies Act of 1978 (Public Law 95-617) (PURPA) approved. |
| 12-08-78 | Kitimat Pipe Line Ltd. applied to DOI for consideration under Title V of PURPA. |
| 12-08-78 | Northern Tier Pipeline Company applied to DOI for consideration under Title V of PURPA. |
| 12-08-78 | Northwest Energy Company applied to DOI for consideration under Title V of PURPA. |
| 01-11-79 | DES filed with the Environmental Protection Agency (EPA). |
| 02-06-79 | Trans Mountain Oil Pipe Line Corporation applied to DOI for consideration under Title V of PURPA. |
| 02-06-79 | Federal Register notice announcing public hearings on DES. |
| 03-06-79 | Public hearings were held in Coeur d'Alene, Idaho, and Billings, Montana. |
| 03-07-79 | Public hearings were held in Helena and Glendive, Montana. |
| 03-08-79 | Public hearings were held in Missoula, Montana, and Williston, North Dakota. |
| 03-12-79 | Public hearing was held in Ephrata, Washington. |
| 03-13-79 | Public hearings were held in Crookston, Minnesota, and Olympia, Washington. |
| 03-14-79 | Public hearings were held in Minot, North Dakota, and Seattle, Washington. |
| 03-15-79 | Public hearings were held in Bismarck, North Dakota, and Port Angeles, Washington. |
| 03-19-79 | Public hearing was held in Juneau, Alaska. |
| 03-20-79 | Public hearing was held in Skagway, Alaska. |
| 03-21-79 | Public hearing was reconvened in Juneau, Alaska. |
| 04-02-79 | End of period for public comment on DES. |
| 04-16-79 | Deadline for submission of project information from Title V applicants. |
| 05-22-79 | Federal Register notice announcing that FES would be available in August and that there would be a period for public comment on the FES. |
| 06-13-79 | The Coordination Committee met for a status report on the preparation of the FES. |

| | |
|---|---|
| 08-15-79 | Expected date for filing FES with EPA. |
| 09-27-79 | Expected end of period for public comment on FES. |

Organization of the Environmental Statement Team

The group responsible for preparation of the ES consisted of a project manager with staff for interagency coordination and public involvement, administrative support, technical analysis, typing, editing, preparation of graphics, and production. The technical team included specialists in the following disciplines:

- Air Quality and Noise
- Archaeology
- Economics
- Environmental Sciences
- Freshwater Fish Biology
- Geography
- Geology
- Hydrology
- Landscape Architecture
- Land Use
- Marine Biology
- Oceanography
- Engineering
- Sociology
- Soil Science
- Wildlife Biology
- Recreation

## 10.2 Data Collection

Data was collected by the BLM environmental statement team, five contractors, and seven federal agencies which had interagency agreements with BLM.

The environmental statement team collected data from federal, state, local, and private agencies. Under most circumstances the environmental statement team gathered and analyzed existing data. Data were collected through correspondence, telephone conversations, personal contacts, and field trips.

Contractors

BLM let six contracts during the preparation of the ES. BLM defined the contract work and reviewed, analyzed, and if necessary, revised the contract work before it was used.

Work was contracted to the following firms:

Fugro, Inc.

Fugro performed water quality analysis and geotechnic analysis along portions of the proposed NTPC pipeline route. Data collected includes information on soils, geology, hydrology, and water quality.

Oceanographic Insitute of Washington (OIW)

The work performed by OIW included analyses of the risks and trajectories of oil spills from tankers in-transit and at-berth, from fuel barges, storage tanks, and the pipeline for the NTPC proposal and several alternate port sites. The study also included a fire and explosion risk analysis for proposed NTPC facilities.

Oregon State University (OSU)

OSU tabulated and mapped existing land uses (i.e., urban, agricultural, rangeland, forestland, wetlands) within a 10 mile radius of NTPC's proposed port and onshore storage facilities. OSU also tabulated and mapped existing land uses along a 2-mile corridor of the portions of the pipeline alignment proposed by NTPC.

Science Applications, Inc. (SAI)

SAI prepared air quality analyses that included a description of the environment, environmental impacts resulting from the proposed action, mitigating measures, and impacts of alternative ports.

The principal study area was the NTPC port and onshore storage facilities area near Port Angeles, Washington. The study area also included the NTPC pipeline corridor and delivery facility sites.

SRI, International

The purpose of the SRI study was to collect social and economic data on existing and future conditions in communities potentially affected by the NTPC proposal and alternative route and port sites. Information was obtained on population, employment, income, taxes, and community facilities and services.

Boeing Computer Services

The purpose of the contract was to provide assistance in developing and maintaining a project management system, including computer time for schedule adjustments, graphic network displays, and tabular reports needed for project management.

Memos of Understanding and Interagency Agreements

Interagency agreements and memos of understanding were signed between BLM and seven other federal agencies: the Army Corps of Engineers, Department of Energy, Fish and Wildlife Service, Forest Service, Geological Survey, National Oceanic and Atmospheric Administration, and Soil Conservation Service. The agreements were established to hasten collection and analysis of data. The agencies provided BLM with copies of relevant environmental data from their files, collected and analyzed additional data in areas where they had specific expertise or program responsibility, and reviewed and provided comments on the ES as it was being prepared.

Other Assistance--Canadian

On March 21, 1978, members of the environmental statement team held informational meetings with the Canadian Department of Environment and Fisheries, and the Canadian Coast Guard, Ministry of Transportation, in Vancouver, British Columbia. In October 1978, members of the environmental statement team met with Fisheries Canada and Environment Canada. The major purpose of the meeting was to gain information on marine resources which could be affected by oil spills which could occur if the NTPC proposal or certain alternatives were constructed and operated.

In the FES potential impacts to Canadian resources are only briefly identified and not analyzed systematically. This treatment reflects a decision based on Executive Order 12114, which is explained in the Introduction to the FES.

## 10.3 Coordination Committee

A committee was established to coordinate activities between federal, state, and local agencies. The goal of the committee was to insure that the ES meets, to the greatest extent possible, the needs of permitting agencies.

The committee met twice during the data collection phase of preparation of the ES. A preliminary draft ES (PDES) was distributed to the committee and a meeting was held jointly to consider the comments on the PDES. The following federal, state, and local agencies were represented on the committee:

Federal

- Department of the Interior
  - Bureau of Indian Affairs
  - Bureau of Reclamation
  - Fish and Wildlife Service
  - Geological Survey
  - National Park Service

- Department of Agriculture
  - Forest Service
  - Soil Conservation Service

- Department of Commerce
  - National Oceanic and Atmospheric Administration

- Department of Defense
  - Army Corps of Engineers

- Department of Energy
  - Region X Office
  - Bonneville Power Administration

- Environmental Protection Agency
  - Region X Office

- Department of Transportation
  - Federal Highway Administration
  - U.S. Coast Guard

State

- State of Idaho
  - Bureau of Community Affairs

- State of Minnesota
  - Department of Natural Resources

- State of Montana
  - Department of Natural Resources and Conservation

- State of North Dakota
  - Energy and Natural Resources Coordinator

- State of Washington
  - Energy Facility Site Evaluation Council

Local

- Board of County Commissioners
  - Clallam County, Washington

- City Manager
  - Port Angeles, Washington

## 10.4 Public Involvement

It was the intent of the environmental statement team to promote public participation in all stages of the project. The goals were to maximize public involvement throughout the entire environmental statement process and to insure that public inputs and concerns were effectively considered and incorporated in the ES. Some components of this effort are described below.

News Releases

Six BLM news releases have been issued since the start of the environmental statement process. The first release was October 4, 1977, announcing BLM's task of preparing an environmental statement for the NTPC proposal. The second news release was February 22, 1978, announcing informal public meetings to be held along the proposed route. On July 18, 1978, it was announced that another set of informal public meetings would be held along NTPC's amended proposed route. A news release on January 12, 1979, announced the availability of the DES on the NTPC proposal. On February 16, 1979, public hearings on the DES were announced and four applicants which had filed for consideration under Title V of PURPA were identifed. On May 22, 1979, it was announced that the Department of the Interior will solicit comments on the four crude oil transportation systems proposed by the Title V applicants by establishing a period for public review and comment on the FES.

Solicitation of Public Inquires

In November 1977, a brochure entitled "Environmental Statement Procedure--Northern Tier Pipeline System" was produced. The brochure described the proposed route, lands to be crossed, areas to be served, sources of crude oil to be transported, the environmental statement procedure, and public participation process. The purpose of the brochure was to encourage public participation in the environmental statement preparation process.

The mailing list used to distribute public information notices has been continually expanded and updated. Public agencies, private individuals, newspapers, radio and television stations are on the list. As of July 1979, the mailing listed included more than 2,000 entries.

A toll free number, (800) 547-5532, was installed to provide the public with easy access to the environmental statement team throughout the preparation of the statement. Since responses to public inquiries are too numerous to be placed in the environmental statement, the correspondence pertaining to inquiries not answered by telephone are on file and open to public inspection.

Public Meetings

Prior to the completion of the DES, 12 informal public information meetings were held along the proposed pipeline route. The first set of meetings was held in March 1978.

Those meetings were held at:

| | |
|---|---|
| Port Angeles, Washington | March 8 |
| Olympia, Washington | March 9 |
| Missoula, Montana | March 14 |
| Coeur d'Alene, Idaho | March 15 |
| Spokane, Washington | March 16 |
| Billings, Montana | March 21 |
| Bismarck, North Dakota | March 22 |
| Crookston, Minnestoa | March 23 |

Because of a proposed route change by NTPC in April 1978, additional information meetings were held in August at:

| | |
|---|---|
| Grand Forks, North Dakota | August 1 |
| Minot, North Dakota | August 2 |
| Williston, North Dakota | August 3 |
| Helena, Montana | August 4 |

Public Hearings

Public hearings were held in March 1978, to receive comments on the DES. All testimony was recorded and transcribed and the transcripts are open to public inspection. Information about the hearings follows:

| Date | Place | Approximate Number Attending | Number Testifying |
|---|---|---|---|
| March 6 | Coeur d'Alene, ID | 35 | 6 |
| March 6 | Billings, MT | 30 | 8 |
| March 7 | Helena, MT | 45 | 8 |
| March 7 | Glendive, MT | 45 | 5 |
| March 8 | Missoula, MT | 140 | 33 |
| March 8 | Williston, ND | 35 | 4 |
| March 12 | Ephrata, WA | 35 | 8 |
| March 13 | Crookston, MN | 15 | 5 |
| March 13 | Olympia, WA | 50 | 10 |
| March 14 | Minot, ND | 25 | 4 |
| March 14 | Seattle, WA | 55 | 12 |
| March 15 | Bismarck, ND | 30 | 10 |
| March 15 | Port Angeles, WA | 150 | 51 |
| March 19 & 21 | Juneau, AK | 35 | 10 |
| March 20 | Skagway, AK | 110 | 20 |

## 10.5 Consultation Required by Statute

The environmental statement team has consulted with those agencies having jurisdiction or special expertise in accordance with the requirements of the Fish and Wildlife Coordination Act, the National Historic Preservation Act, the Endangered Species Act, and other applicable acts relating to the four crude oil transportation system proposals.

Consultation has been initiated with U.S. Fish and Wildlife Service and the National Oceanic and Atmospheric Administration concerning possible effects of the proposals on endangered and threatened species. In July 1978, BLM requested consultation, as required under Section 7 of the Endangered Species Act, from the Fish and Wildlife Service (FWS) concerning the NTPC project as then proposed. In April 1979, FWS responded and identified six threatened or endangered species that could be affected by the NTPC proposal. The potential impacts on those species are discussed in the Terrestrial Wildlife sections of chapter 3 or in the appropriate sections on Route Segment Alternatives of the Northern Tier Pipeline Proposal in chapter 9 of the FES.

In July 1979, BLM amended its request for consultation from FWS to include consideration of the portions of NTPC's proposed route which has been changed since the original request, and to consider the U.S. sections of the proposals from the other two Title V applicants. Since that time BLM has responded to requests from FWS to provide additional information about the potential areas of impact of the several proposals. At the time of final preparation of the FES this process of consultation was continuing.

In July 1979, BLM also requested information from the National Marine Fisheries Service (NMFS) concerning endangered species and their habitats as provided for under Section 7(c) of the Endangered Species Act. All four of the Title V proposals would involve tanker sea legs from Valdez, Alaska, and from foreign ports in U.S. territory. This consultation process was also continuing at the time of final preparation of the FES.

Following discussion with the Advisory Council on Historic Preservation, BLM initiated consultation with the Advisory Council and the State Historic Preservation Officers of the five states which would be affected by the NTPC proposal. The purpose of the consultation was to develop an adequate course of action for compliance with Section 106 of the Historic Preservation Act should NTPC's proposed project be approved. In July 1978, BLM initiated the process to establish a Memorandum of Agreement with the Advisory Council and the State Historic Preservation Offices which would state how BLM would proceed to comply with Section 106 and other applicable laws. The procedure which was established would also apply to the proposals from NEC and TMC. If one or more of the proposed systems which would affect cultural resources in the United States is approved, a Memorandum of Agreement would be established between the appropriate consulting agencies.

The Council on Environmental Quality regulations note that the Office of Management and Budget Circular A-95 (Revised) provides a means of securing the views of state and local environmental agencies through its system of clearinghouses. Copies of the DES were sent to statewide clearinghouses of the six states which would be affected by one or more of the proposed projects and to appropriate areawide clearinghouses.

## 10.6 Distribution of the Environmental Statement

The DES was available for public inspection at the BLM office of Public Affairs in Washington, D.C., at BLM state and district offices in areas that would be affected by one or more of the proposals, and at most city and county offices and public libraries along the proposed pipeline routes. Approximately 1,500 copies of the DES were distributed for review to federal, state and local agencies, members of Congress, to the U. S. Department of State for distribution to interested agencies of the government of Canada, and to public and private interest groups and individuals.

The FES will be available for public inspection at the same places noted in the paragraph above. The FES will be distributed to those who received the DES, to organizations and individuals that made comments on the adequacy of the DES, and to those who request the FES from the BLM.

## 10.7 Comments Received on the Draft Environmental Statement and Responses

A total of 250 comment letters were received from 31 federal agency offices, 2 Indian tribal organizations, 38 state agency offices, 34 local government agencies, 42 organizations, and 103 individuals. The comment letters were numbered consecutively as they were received by the environmental statement team. Those letters postmarked before the end of the public comment period (through April 2, 1979) are numbered 1 to 180. Additional letters, postmarked from April 2 through May 15, 1979, are numbered L-1 through L-60. Some numbers were mistakenly assigned to pieces of correspondence which were not official comments on the DES, and they are so noted in the list of comment letters received. Occasionally a number was assigned to a comment letter which actually contained several discrete parts and the parts are indicated by capital letters following the number (for example 82A and 82B). All numbered comment letters are printed in the following pages. All comment letters postmarked after May 15 were reviewed and filed but could not be included in the FES.

Comments are numbered in consecutive order on each letter, with the exception of comment letter 126, where each titled section is numbered separately. Most comments and responses can be identified by a letter number followed by a comment number (70-12 or L-13-46). Comments and responses for comment letter 126 are identified with a word as well, for example: 126-Alternatives, 83. All responses are printed in the responses to comments section which follows the entire comment letters section. The list of comment letters received indicates the page numbers of the letter and its responses, if any. Also, at the end of chapter 10, there is a comment letter index in which the letters are arranged in categories.

Comments which provided relevant information, which raised questions about the adequacy of the DES, or requested clarification about procedures or analyses were responded to specifically. Specific responses were written for all such comments contained in Letters 1 through 180. For letters L-1 through L-60 specific responses were written only for those letters received from federal agencies. All other letters with L-numbers were reviewed by the appropriate members of the environmental statement team. Revisions in the text of the FES were made if required, but no specific responses were written for publication in chapter 10.

General responses, as well as responses to specific comments, were written for a number of comment letters in order to explain an overall approach to issues or questions raised by the letters. Similar comments were often made by more than one reviewer. In most cases a response has been written for the comment the first time it is raised, with later comments being referred back to the full response. A number of sections of the FES (such as Biological Components of Marine Resources) are complete revisions of the DES material. In many cases the response to comments on those sections is simply to refer to the revised section of the FES.

A total of 194 people gave testimony at the 15 public hearings held during March 1979. None of that testimony has been printed in the FES. Many speakers were indicating their support or opposition to one or more of the proposals. A number of the speakers sent in written copies of their testimony which have been included among the comment letters. These materials which either did not require a response or which duplicated other comments were eliminated from consideration. Then the remainder of the testimony was carefully examined by the environmental statement team to see if any issues pertinent to the adequacy of the DES were raised which had not already been identified and responded to by either revisions in the FES or written responses in chapter 10. No pertinent new comments were identified.

A number of general concerns were raised frequently in comment letters and hearing testimony. Many people, especially those along proposed pipeline routes, requested site specific details about the nature and precise location of potential impacts. They often indicated that they believed the DES to be inadequate because of this lack of detailed impact analyses. It is true that this ES lacks site specific analyses, especially along proposed pipeline routes. This is unavoidable since this ES is a report on the analysis of four proposals, each of which is only in the early stages of planning. Responsible planning and regulation of projects of the scale of major trans-continental pipeline systems require that relatively general environmental analyses be performed during the preliminary stages of project development. Some specific potential impacts and many general types of potential impacts have been identified. This makes it possible for later stages of planning and project review to include consideration of environmental variables and to incorporate route adjustments if appropriate. However, because of the nature, purpose, and timing of this ES, it has generally not been possible to evaluate potential impacts of the proposals on particular resources at specific, precise locations.

Residents of two areas, Island County in western Washington, and the Ninemile Valley in western Montana, provided numerous comments on the inadequacy of the DES treatment of resources in their areas. Both are areas which were only recently identified as revised locations for the proposed pipeline routes. Many people in the Island County area requested that BLM extend the public comment period beyond April 2, 1979, and that BLM issue a revised DES. The decisions about issuing the FES and providing a period for public review and comment of the FES are outlined in the Introduction to the FES. Expanded discussions of the Puget Sound area are included in the sections on the NTPC and the TMC proposals, and the discussion of potential impacts in the Ninemile Valley are incorporated into the sections in the NTPC proposal.

Another major area of concern expressed in comments is the potential for adverse impacts at Port Angeles, Washington, the proposed site for the NTPC port facility. These concerns have been presented and responded to in great detail in the comment letters and responses to comments which follow.

The general topic of greatest concern to many reviewers is the potential for oil spills, both at sea from tankers and on land from pipelines. Considering that an oil spill could have impacts on virtually all components of the environment, it is not surprising that it is a major concern. The sections on the FES which deal with Oil Spill, Fire, and Explosion Risk Analyses are more complete and detailed than was possible in the DES. In addition, potential impacts have been identified more clearly in the impact analysis sections of the FES. Finally, many responses were written to specific comments about oil spill risk analyses leak detection systems, and potential oil spill impacts.

LIST OF COMMENT LETTERS RECEIVED

| LETTER NO. | AGENCY OR INDIVIDUAL |
|---|---|
| 1 | Peter Suenpolla, Ashland, OR |
| 2 | City Plan Commission, Spokane, WA |
| 3 | Mary Pinkham, Seattle, WA |
| * 4 | State of Washington, Planning and Community Affairs Agency, Olympia, WA |
| 5 | Mrs. Harry B. McFarland, Port Angeles, WA |
| 6 | Emmy K. Ibison, Bozeman, MT |
| 7 | John David Gilbert, Bozeman, MT |
| * 8 | U.S. Dept. of Health, Education & Welfare, Region VIII, Denver, CO |
| 9 | Comment number assigned in error |
| * 10 | U.S. Dept. of Transportation, Federal Aviation Administration, Rocky Mountain Region, Aurora, CO |
| * 11 | Montana Historical Society, Historic Preservation Office, Helena, MT |
| 12 | Eileen J.K. Holmes, Port Angeles, WA |
| * 13 | U.S. Dept. of Housing & Urban Development, Region X, Seattle, WA |
| * 14 | Michael J. Howell, Jr., Wallace, ID |
| 15 | North Dakota State Planning Division, Bismarck, ND |
| * 15A | Williston Basin Regional Council, Williston, ND |
| * 15B | Ward County County Commission, Kenmare, ND |
| 15C | Pierce County County Commission, Orrin, ND |
| * 15D | University of North Dakota, Dept. of Geology, Grand Forks, ND |
| 16 | U.S. Dept. of Transportation, U.S. Coast Guard, Ninth District, Cleveland, OH |
| 17 | North Dakota State Planning Division, Bismarck, ND |
| 17A | Governor's Office, State Capitol, Bismarck, ND |
| * 17B | City Planning & Zoning Commission, Grand Forks, ND |
| * 18 | Eric Wunz, Shelton, WA |
| 19 | Robert Cerrier, Bozeman, MT |
| * 20 | U.S. Dept. of Transportation, Federal Aviation Administration, Northwest Region, Seattle, WA |
| 21 | Beth Yount, Belgrade, MT |
| * 22 | Department of Public Utilities, Tacoma, WA |
| * 23 | State of Washington, Dept. of Natural Resources, Olympia, WA |
| * 24 | U.S. Dept. of Transportation, Federal Highway Administration, Region 5, Homewood, IL |
| * 25 | U.S. Dept. of Interior, Fish & Wildlife Service, Twin Cities, MN |
| * 26 | U.S. Dept. of Interior, Heritage Conservation & Recreation Service, Lake Central Region, Ann Arbor, MI |
| * 27 | Clallam County Fire District #3, Carlsborg, WA |

* COMMENT LETTERS WHICH HAVE RECEIVED SPECIFIC RESPONSES ARE INDICATED WITH AN ASTERISK.

| | |

January 10, 1979

Bureau of Land Management
U.S. Department of the Interior
Oregon State Director
Portland, Oregon

Gentlemen:

We have received and reviewed the Draft Environmental Statement for the Crude Oil Transportation System. The primary route now proposed is along the southern border of Spokane County and thus will have a minimal environmental effect on the City of Spokane. We are pleased to note that the line will not traverse the Spokane Valley aquifer, the source of Spokane's water supply.

In general we support the proposal and stand ready to aid in any way that we can to see this project completed.

Sincerely,

E. Terry Clegg,
Planning Director

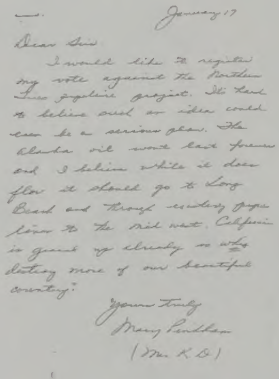
**3**



January 17

Dear Sir

I would like to register my vote against the Northern Tier pipeline project. It's hard to believe such an idea could even be a serious plan. The Alaska oil won't last forever and I believe while it does flow it should go to Long Beach and through existing pipe lines to the mid west. California is giving up already so why destroy more of our beautiful country?

Yours truly
Mary Pendleton
(Mrs. K. D.)

STATE OF WASHINGTON
Dixy Lee Ray
Governor

PLANNING & COMMUNITY AFFAIRS AGENCY
[illegible]
Dean Cole, Director

January 18, 1979

Mr. Ron Sundell
U.S. Bureau of Land Management
Oregon State Office
729 N.E. Oregon St.
Portland, Oregon 97208

Dear Mr. Sundell:

The Planning and Community Affairs Agency is a service agency which is responsive to local government. Among one of our tasks is to provide notification to cities and counties through our A-95/EIS Log if a major project would affect or involve a particular county. We also notify the lead agency of a possible oversight as a matter of routine.

① The BLM Northern Tier EIS distribution list did not indicate that King, Pierce and Thurston counties were distributed copies of the EIS. If the BLM Northern Tier draft EIS distribution list is correct, I would suggest that those jurisdictions receive a copy of the draft.

Cordially,

Mike Wong

135 W. 2nd
Port Angeles, Wa.
98362
1/22/79

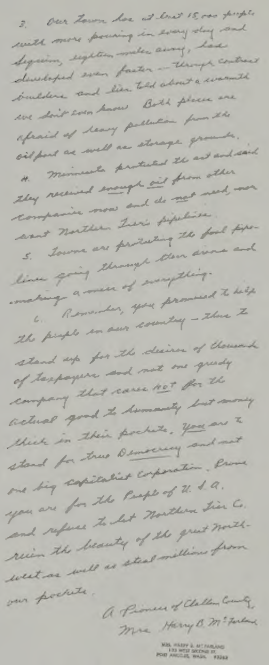
State Director
BLM
P.O. Box 2965
Portland, Ore.

Dear Sir:

You are considering Northern Tier's proposition of unloading oil at Port Angeles, Wash. to go through a 1,557 mile pipeline to Minnesota. Please remember the following:

1. Millions spent on an unneeded pipeline as Canada will put one through and there are already lines in California to be used. Therefore U. S. Steel Co. is simply trying to take unnecessary millions from the taxpayer for their greedy profit. The people know that U. S. Steel is the main company of Northern Tier. Help America — not the thief!

2. We are a main source for large salmon and a few small oil spills going east or west will do a lot of harm. There are continuous small spills with steady unloading and the water currents here are strong and could [illegible] carry oil away to do harm.



3. Our town has at least 15,000 people with more pouring in every day and Sequim, eighteen miles away, has developed even faster — through contract builders and lies told about a warmth we don't even know. Both places are afraid of heavy pollution from the oil port as well as storage grounds.

4. Minnesota protested the act and said they received enough oil from other companies now and do not need, nor want Northern Tier's pipeline.

5. Towns are protesting the fuel pipe-lines going through their towns and making a mess of everything.

6. Remember, you promised to help the people in our country — there to stand up for the desires of thousands of taxpayers and not one greedy company that cares NOT for the actual good to humanity but money thick in their pockets. You are to stand for true Democracy and not one big capitalist corporation. Prove you are for the People of U. S. A. and refuse to let Northern Tier Co. ruin the beauty of the great North-west as well as steal millions from our pockets.

A Pioneer of Clallam County,
Mrs. Harry B. McFarland

JAN 24, 1979

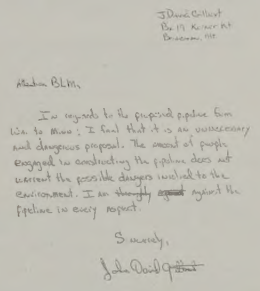
Dear BLM -

In regards to the proposed pipeline extending from wash to Minn, I feel the last thing our state needs is an oil pipeline The increadable costs don't justify the minimal amount of people that would be employed (putting how many truckers, & railroad people out of work?) Not to mention the environmental destruction that would occur during construction, & any oil spills from equipment failure and vandalism.

I am against any pipeline in Montana—

Box 19 Kenner Kourt
Bozeman, MT 59715

**7**



J David Gilbert
Box 19 Kenner Kt
Bozeman, MT

Attention BLM,

In regards to the proposed pipeline from Wa. to Minn; I feel that it is an unnecessary and dangerous proposal. The amount of people engaged in constructing the pipeline does not warrant the possible dangers involved to the environment. I am ~~thoroughly~~ ~~against~~ against the pipeline in every respect.

Sincerely,

John David Gilbert

DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE

January 26, 1979

ROFEC

Mr. Murl W. Storms
Director
Oregon State Office
Bureau of Land Management
Department of Interior
729 N.E. Oregon Street
P.O. Box 2965
Portland, Oregon 97208

Dear Mr. Storms:

This will acknowledge receipt of your Draft Environmental Statement for the Crude Oil Transportation System from Port Angeles, Washington to Clearbrook, Minnesota.

We wish to offer the following comments:

① 1. There are no assurances of compliance with Federal Health and Safety Standards (OSHA) during construction and operation.

2. There are no references to State Safety and Health Standards.

② 3. The issue of medical care for work-related emergencies has not been adequately addressed. Many of the hospitals described as being "within 50 miles" of the pipeline construction site would not be able to deal with the severe trauma of construction accidents. In addition, appropriate transportation from the construction site to medical care for the injured is not addressed.

③ 4. There seems to be a good analysis of the severe impact on local housing conditions along the pipeline construction route. However, all proposed methods to minimize the impact (HUD loans, temporary housing developments, etc.) require more lead time than is available under the proposed construction schedule. The result could be:

a. Overcrowding of existing available housing.

b. Development of substandard temporary housing that will overload water, sewage and trash removal capabilities.

c. Inappropriate "camps" sprouting up around worksites with limited sanitary facilities.

④ 5. The draft states that there should be no significant impact on the school systems within the areas of the project; however, very little data is given to back up that statement. It is recommended that before a final EIS is prepared, these school districts be consulted and their comments be made a part of the document.

Sincerely yours,

Thomas E. Moore
Director, ROFEC
Regional Environmental Officer

DEPARTMENT OF TRANSPORTATION
FEDERAL AVIATION ADMINISTRATION

ROCKY MOUNTAIN REGION

FEB 5 1979

Bureau of Land Management
Attention: State Director
700 N E Multnomah
Suite 1250
Portland, Oregon 97232

Dear Sir:

We have reviewed your draft environmental statement, Crude Oil Transportation System, as proposed by Northern Tier Pipeline Company.

① The potential impact of the pipeline on aviation activities seems to be negligible. However, it is possible that pipeline construction, when passing in proximity to air navigational aids and/or airports, could have a detrimental effect on aviation related equipment or airport operations. In that case, we recommend that a Notice of Proposed Construction or Alteration, FAA Form 7460-1, as required by Federal Air Regulation, Part 77, be filed.

When you encounter this situation and have any questions, please contact the FAA Rocky Mountain Region Planning Staff, ARM-4, 10455 East 25th Avenue, Aurora, Colorado 80010.

Thank you for the opportunity to review your draft environmental statement.

Sincerely,

for Kenneth Thompson
FRED M. JAEGER, JR.
Chief, Planning Staff

Portland, OR 97208

RE: draft EIS, Northern Tier Pipeline

Dear Sir:

① Thank you for the opportunity to comment on the above environmental statement. My main concern is that the document addresses only archaeological and historical properties which have been identified from state survey files or site compendiums. Since only a fraction of the whole state of Montana has been surveyed for cultural resources, the archaeological and historical site data provided in the draft statement represents an incomplete and inadequate data base for discussion of the effects of the pipeline project on cultural resources.

② Adequate time schedules to fully assess cultural resources not yet identified, as well as assessment of the identified cultural resources, must be allowed so that compliance with E.O. 11593, sec. 106 of the Historic Preservation Act, NEPA requirements, and the Advisory Council's procedures in 36CFR800 can be completed prior to ground disturbance.

③ At this time the draft statement is incomplete in its treatment of archaeological and historical resources. My office staff and I will be happy to assist the BLM so that the requirements can be met.

Sincerely,

Ken Korte
State Historic Preservation Officer

2/3/79

State Director
Bureau of LandManagement,
P.O.Box#2965.
Portland Oregon.97208

Dear Sir,

This is in response to the BLM newsletter regarding the proposed crude oil, transportation system from Port Angeles Wa. to Clearbrook Minnesota.

As public comment is invited I would like to add my input to the concerned citizensof this area who are opposed to this facility. I have lived in areas of Canada and California that house similar establishments to the one proposed for this area and can only shake my head in wonderment at the shortsightedness of the idiots who back such a proposal.It is evident that they have never lived with such danger in their immediate environs and if they wish to live dangerously, I suggest they move to an area where they can gaze at the pollution and despoilment of nature that such an operation brings with it.

Most of the people who live in this area obviously choose to live here, we like it as it is,and we do not wish to see it altered in any way.I could meander at great length on the hazards of an oilport here in Port Angeles,you men of intellect know the why-nots however, as well as I, and they outweigh any positive aspect you can put forward, although I must confess I find no affirmative thoughts regarding a Port Angels oilport,only horror, weigh your decision carefully, because nature, once despoiled, can never be regained.

Label me,"A Concerned Citizen" Eileen JK Holmes (Eileen JK Holmes)

Mr. L. Leonard, Project Manager
700 N. E. Multnomah
Suite 1250
Portland, Oregon 97232

Dear Mr. Leonard:

Re: Draft Environmental Statement
Crude Oil Transportation System
(Northern Tier Pipeline Company)

We have reviewed the draft statement dated January 3, 1979.

Although the location of the pipeline is not site specific, we believe you have adequately analyzed the impacts in our areas of concern.

① The expected employment build-up which is described in detail should allow communities to plan for needed housing and associated community facilities. We would like to see the pipeline location conform to local zoning. ② We are aware of some of the concerns expressed by some communities. Perhaps to alleviate some of the concerns, the degree of hazards from explosion, fire or odor can be better defined. ③ You state the pumping stations are a source of high noise. We would like to see mitigating measures incorporated where they would be located near residential areas. We strongly support your plan not to locate the pipeline over the Spokane Valley Rathdrum Prairie Sole Source Aquifer.

We defer to other agencies to comment on areas not within our areas of expertise or jurisdictions.

Thank you for the opportunity to comment.

Sincerely,

Robert C. Scalia
Director
Regional Office of Community Planning
and Development

Northern Tier Pipeline Project
c/o BLM State Director
700 N.E. Multnomah
Suite 1250
Portland, Oregon 97232

210½ Cypress St.
Wallace, Idaho
February 12, 1979

Dear Sir:

I have just completed reading the draft environmental statement reviewing the proposed pipeline. Despite my general opposition to such large scale abuse of the land I am certain that one of the proposed alternatives will be implemented. In that case the thoroughness of the planning of the northern tier route is impressive. If all of the safeguards in the environmental statement are enforced I would have only three specific objections regarding the route.

The plan to use Port Angeles and Green Point is the most serious fault in the whole plan. It requires the crossing of all of the major and minor streams and rivers at their junction, or near it, with the whole southern half of Puget Sound. This route includes acknowledged prime habitat for raptors, marine mammals, waterfowl, fish, and invertebrate marine animals. It also passes through areas of instable soil. This intentional crossing of a major fresh and salt water interface is unacceptable because it is one of the most productive and at the same time threatened habitat types in the

① country. I strongly suggest that Grays Harbor in the area of Hoquiam be considered for the origin of the route. The pipeline could parallel existing transportation arteries to Olympia where it could continue along the planned route. This would remove it from much of the area where the greatest potential for severe biological impact exists. This alteration would not significantly increase the tanker travel distance. Restrictions requiring a minimum distance of travel from the coast until the tankers reached Grays Harbor would allow a safety buffer zone not present in the original plan regarding near coast spills. A spill in the open ocean would cause less damage by being farther from critical habitat rather than directly introduced into the current in the Strait of Juan DE Fuca which would propel the oil into the salt marshes. By requiring the tankers to travel at a safe distance from the coast until they are offshore from Grays Harbor the time margin available for control in the case of a spill is increased.

② My second objection to the route is actually more of a constraint. In the vicinity of Lake Coeur d'Alene and the marshes upstream to Mission Flats the pipeline is planned to make the most economical traverse possible by running in straight segments which repeatedly cross these marsh areas. I feel that because this area holds the largest remaining population of osprey in the U.S. and one of the largest easily visible populations of eagles in the winter, and prime migratory waterfowl stopping areas for Canada geese, swans, and numerous species of duck the route should be averted from the water as much as possible. Once the pipeline reaches the area of Plummer it should remain on the south side of the Coeur d'Alene river away from the marshes. This can be accomplished with less difficulty than the Idaho-Montana border crossing with regard to elevation gained. The slope of the foothills above the marshes is not severe enough to pose construction problems other than following the contour of the slopes to Cataldo. At that point only one well constructed crossing of the river would be necessary.

③ My final objection would be to the construction proposed in Montana between Thompson Falls and Helena. The numerous crossing and recrossing of most of the major rivers of western Montana especially in unstable soil and strong seismic activity areas poses a severe threat in the case of a spill. The draft statement outlined the safeguards but nowhere was the estimated quantity of oil that would escape even with the safeguards mentioned. That leads me to believe that it is either difficult to predict or of sufficient magnitude that the public would be alarmed by including this in the report. I want to see more detail about actual control times and quantity of oil spilled in the final statement. This can surely be predicted by a fairly simple computer model for various locations along the pipeline, especially in proximity to waterways. As for the route through Montana I feel it should be redesigned to cause the minimum number of river crossings possible, which may not necessarily be the cheapest construction route for the Northern Tier Pipeline Company.

Thank you for reading these comments and I sincerely hope that they are helpful in finding the most compatible solution between energy and conservation needs.

Sincerely,

Michael J. Howell Jr.

Bureau of Land Management
Oregon State Office
P.O. Box 2965
Portland, Oregon 97208

Dear Mr. Hamerski:

Subject: Draft Environmental Impact Statement for the Crude Oil Transportation System.

This Draft EIS was received in our office January 11, 1979.

Thank you for submitting your draft environmental impact statement for review and comment through the North Dakota State Intergovernmental Clearinghouse.

In the process of review, the University of North Dakota, the Pierce County County Commissioner, Ward County Commissioner and from the Williston Basin Regional Council offered the attached comments, which should be addressed in the preparation of your final environmental impact statement.

Please send copies of the final environmental impact statement and any supplemental impact statements to the North Dakota agencies that have commented on the draft, and to this office. The opportunity to review your draft is appreciated, and if this office as Clearinghouse can be of further assistance with this project, please let me know.

Sincerely yours,

① A RESOLUTION CONCERNING THE POTENTIAL IMPACT OF THE PROPOSED NORTHERN BORDER AND NORTHERN TIER PIPELINES ON THE WILLISTON BASIN REGION

WHEREAS, Northern Tier (Crude Oil) Pipeline and Northern Border (Natural Gas) Pipeline are proposed to cross Region I and both will be crossing the Missouri River in or near the Region; and

WHEREAS, such pipeline and river crossing construction could entail several hundred construction workers; and

WHEREAS, Region I is already experiencing a local oil development boom with area housing vacancy rates of 1% or less and unemployment rates of only 2% or 3%; and

WHEREAS, the Northern Border Pipeline proposes to cross irrigated lands in Williams County which are the only irrigated lands this pipeline proposes to cross; and

WHEREAS, the presence of these two pipelines together with Region I resources of coal, major water supplies, major rail service, potash reserves, and deep salt beds may inevitably commit the counties of Region I to massive future industrial development;

NOW THEREFORE BE IT RESOLVED, that the Williston Basin Regional Council for Development encourages a dialogue between citizens, elected officials, state agencies, federal agencies, and pipeline companies by taking the following course of action:

a. Formally request our U.S. Congressman and U.S. Senators to investigate this issue with the Federal Department of Energy.
b. Formally request the Bureau of Land Management and ND Public Service Commission to examine the decision to cross irrigated land in the Northern Border's EIS.
c. Host an information meeting in Region I with representatives available from the Northern Tier and Northern Border pipelines, the Bureau of Land Management, the Department of Energy, the Defense Department's Strategic Storage Program, Governor's Natural Resource Council and North Dakota Public Service Commission.

SIGNED THIS DATE, ____________, 1978 in Williston, ND.

Roger L. Sanders, Chairman

State Capitol, Bismarck 58505

A review of the Draft EIS for the Crude Oil Transportation System submitted by the Northern Tier Pipeline Company has indicated that a complete evaluation of the environmental impact of the project on specific sites in North Dakota requires consideration of geologic information on a more specific scale than that used in the Draft EIS. Included below are comments intended to aid in generation and consideration of such information.

① 1) Data on maximum flood scour depths of the major rivers crossed by the pipeline, the Des Lacs, Souris, and Red rivers should be included. This information is necessary to indicate and evaluate proper location and construction techniques at river crossings.

② 2) Near pipeline mile 1470 the proposed route encounters a region of extremely saline soils (locally known as Kellys Slough) resulting from the discharge of saline groundwater. The combination of a year-round high water table and a very saline soil would substantially increase the potential for corrosion of the pipe.

③ 3) The potential for oil spill pollution of water supplies for the cities of Minot and Grand Forks is greatly increased by the location of pipeline river crossings upstream from municipal water intakes. This potential could be easily eliminated by relocating the river crossings downstream from the cities.

④ 4) The landslide potential along the valley walls of the Souris and Des Lacs rivers is not realistically discussed in light of the fact that landslides have been mapped along the valley walls of the Des Lacs River in the area near Donnybrook, N.D. (approx. 20 miles NW of the Des Lacs and Souris river crossings) by Lemke (1960), USGS Prof. Paper 325.

⑤ 5) Evaluation of the impacts on cultural resources, as indicated in the Human Alignment Sheets section of the map addendum, is at best difficult; the legend is much too general. For example, what is the significance of the "P" included within the cultural resources symbol near pipeline mile 1140 on Alignment Sheet 19, page 173? Also, no information regarding paleontologic, archeologic or historic sites is included within the legends or text. And, it seems highly unlikely that there will be only one instance of critical impact on human resources in the entire state, as indicated by the Human Alignment Sheets.

In conclusion, it is hoped that these comments will serve to improve the quality and usefulness of information in the final EIS on this project and therefore aid in minimizing potential adverse effects of the project on North Dakota's environment and citizens.

Sincerely,

Garth Anderson

CITY OF GRAND FORKS
GRAND FORKS, NORTH DAKOTA 58201
CITY PLANNING & ZONING COMMISSION

February 13, 1979

North Dakota Public Service Commission
State Capitol Bldg.
Bismarck, ND 58505

Gentlemen:

① Enclosed find a copy of the minutes of the Grand Forks Planning and Zoning Commission meeting held on February 7, 1979, at which time the Commission took action requesting that the Northern Tier Pipeline Company move its proposed Red River crossing so that it passes north of Grand Forks.

The City of Grand Forks makes this request because of the problems involved in the probability of an oil spill, regardless of how slight, getting into the water supply of the City.

Mr. Don Wilson and Mr. Steve Shores, the Butler Associates representatives, were in attendance and stated that crossing major rivers is very important criteria in selecting the route of the proposed pipeline.

Following the Butler Associates presentation, planning and zoning commission members and citizens in attendance expressed concern about the pipelines proposed route south of Grand Forks. Local concern centered on the possibility of an oil spill affecting the water supply for the City. It was strongly recommended by those in attendance that the Northern Tier Pipeline route be moved north of Grand Forks. Staff of the Grand Forks City Engineering Department gave a presentation that illustrated alternative pipeline routes that could be utilized if a north route decision were implemented. (See Exhibit A)

Other factors which reinforced the north route follows: (1) If the route were north of Grand Forks, it would not be impacting as much agricultural lands that are classified as prime agricultural land. (See Exhibits B and C enclosed (i.e. Soil Classifications and Soil Salinity)). (2) It was pointed out by Butler Associates that it is very important to Northern Tier Pipeline Company that the number of major river crossings be kept to a minimum, and the north route would eliminate one river crossing on the Red Lake River in Minnesota. (See Exhibit D)

In conclusion, there are important reasons for rerouting the Northern Tier Pipeline to the north of the City of Grand Forks. First, if the pipeline was north of the community and an oil spill did occur, the water supply of both Grand Forks and East Grand Forks would not be jeopardized (current metropolitan population of 52,000 people). Second, if the pipeline were routed north less prime agricultural land would be affected. Third, if the

---

**CONT**

Public Service Commission -2- February 13, 1979

pipeline were to run north of the City, one major river crossing on the Red Lake River in Minnesota could be eliminated.

The City of Grand Forks expresses its thanks for being heard and adamantly opposes the pipeline crossing south of Grand Forks, North Dakota.

Very truly yours,

Frank B. Orthmeyer

P. C. PROCEEDINGS -4- February 7, 1979

Commission members, which included the Background Studies, the Land Use Plan, and the Implementation Program. He outlined the entire plan for the members pointing out areas covered in it. Discussion followed Mr. Ulland's presentation. Mr. Orthmeyer complimented the staff for the excellent plan and report. It was agreed by the members present that they study the plan and discuss it further at the March meeting.

NORTHERN TIER PIPELINE COMPANY PRESENTATION ON CRUDE OIL PIPELINE CROSSING IN NORTH DAKOTA

Attorney John Shaft introduced two gentlemen, Don Wilson and Steve Shores, who were present to represent Butler Associates and the Northern Tier Pipeline Company. Butler Associates is one of seven companies which compose Northern Tier Pipeline Company. Mr. Shores gave a brief history of the Northern Tier Pipeline Company and also facts about the pipeline which will stretch from Washington to Clearbrook, Minnesota, stating that the pipeline will travel 344 miles across the state of North Dakota crossing south of Grand Forks. Don Wilson followed with a slide presentation of a pipeline crossing in North Carolina. Following the presentation, there was much discussion. Several people questioned whether Northern Tier Pipeline Co. would consider rerouting the pipeline north of the city. Mr. Orthmeyer asked the representatives of Northern Tier Pipeline Co. to consider rerouting the proposed pipeline North of Grand Forks in order to avoid the possibility of an oil spill into the City water intakes. He used a map illustrating alternative routes, marked Exhibit A. Mr. Shores and Mr. Wilson suggested that the Public Service Commission and the Corps of Engineers be advised of this concern and added that the City of Grand Forks will be notified of the decision that is reached by the company. After further discussion, a motion was made by Mr. Polovitz and seconded by Mr. Malm that we recommend to the Public Service Commission that the pipeline crossing be north of the city. The motion carried. (Exhibit A was sent to the Public Service Commission.)

ADJOURNMENT

A motion was made by Mr. Malm and seconded by Mr. Polovitz that we adjourn until March 7, 1979. The motion carried.

Respectfully submitted,

Frank B. Orthmeyer

Frank B. Orthmeyer, Secretary

C. J. Thomforde, Chairman

FBO/mb

**18**

Gentlemen,

I do not feel that the "Draft Environmental Impact Statement" on the Northern Tier Pipeline completely addresses the impacts on the environment, or explores enough alternatives.

Some major areas of concern:

① 1. Cannot a way be found to cross rivers on a bridgework or suspension system to eliminate the disturbing of the stream channel? This is especially important in such pristine rivers such as those found on the Olympic Peninsula and Hood Canal regions.

② 2. Why isn't a pipeline proposed from the unloading facilities to the tank storage via a land route? This would have less chance of leaking into the harbor and the Strait of Juan de Fuca and potentially be cheaper.

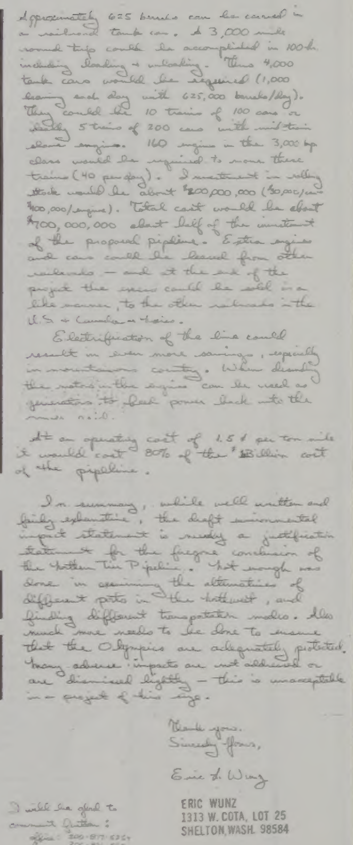
③ 3. Why the "wedge" cut for the pipeline at Green Point? You don't see that on other pipelines traversing rough terrain.

④ 4. We are experiencing some minor electrical power shortages this winter, and the rapidly increasing population of the NorthWest isn't helping. Where is the additional power for the electric pumps coming from? The NorthWest has virtually run out of additional hydroelectric sites, and the nuclear plants are in political + economic trouble.

⑤ 5. Why unload the oil at Port Angeles and pipe it the length of the Olympic Peninsula? It looks to me that Grays Harbor + Aberdeen would have been more logical economically. Also the Olympics are uniquely pristine and even the slightest degradation would have noticeable effect.

⑥ 6. Since the pipeline parallels existing rail lines for much of its length why not explore that alternative. The "Milwaukee Railroad" is in economic trouble and the line could probably be bought for $500 million — scrap value. An Aberdeen — Clearbrook railline would involve little additional impact because the right-of-way is already in place.

CONT



6 Approximately 625 barrels can be carried in a railroad tank car. A 3,000 mile round trip could be accomplished in 100 hr including loading + unloading. Thus 4,000 tank cars would be required (1,000 leaving each day with 625,000 barrels/day). They could be 10 trains of 100 cars or ideally 5 trains of 200 cars with mid-train slave engines. 160 engines in the 3,000 hp class would be required to move these trains (40 per day). Investment in rolling stock would be about $200,000,000 ($30,000/car $400,000/engine). Total cost would be about $700,000,000 about half of the investment of the proposed pipeline. Extra engines and cars could be leased from other railroads — and at the end of the project the excess could be sold in a like manner, to the other railroads in the U.S. + Canada [illegible].

Electrification of the line could result in even more savings, especially in mountainous country. When descending the motors in the engines can be used as generators to feed power back into the power grid.

At an operating cost of 1.5¢ per ton mile it would cost 80% of the $Billion cost of the pipeline.

In summary, while well written and fairly exhaustive, the draft environmental impact statement is merely a justification statement for the foregone conclusion of the Northern Tier Pipeline. 7 Not enough was done in examining the alternatives of different ports in the Northwest, and finding different transportation modes. 8 Also much more needs to be done to ensure that the Olympics are adequately protected. Many adverse impacts are not addressed or are dismissed lightly — this is unacceptable in a project of this size.

Thank you.
Sincerely Yours,

Eric A. Wunz

Regarding: Northern Tier Pipeline Proposal

I have looked over the Draft Environmental Statement for the Northern Tier pipeline. I am opposed to any pipeline, transmission line, or other such construction requiring a corridor cutting thru native lands. A proposal this size would literally dissect the state. There is (and rightly so) much concern for lands in western Montana. I support wilderness advocates and environmentalists in their conclusions. Included but overlooked is the other half of Montana - Townsend to Williston. This route would cut thru almost exclusively native lands where no previous corridor has existed - from the Big Belt Mountains thru the monocline (as the DES calls it) native prairie lands to the North Dakota Border.

Not only ~~then~~ would the Pipeline border Special Care II areas - which seems of little consequence considering the ES final statement - ~~PBR~~ and experimental forest and all municipal stream crossings and wildlife habitat but it passes thru many areas of eastern Montana I would think should be considered 'prime' for BLM wilderness consideration.

The creation of a new corridor is completely unacceptable. The seemingly [illegible] is the following of an existing corridor (ie road, railway) because of increased river crossings, traffic congestion and many other human factors. I can find no compromise and will not propose any alternatives.

Thank you
Robert [illegible]

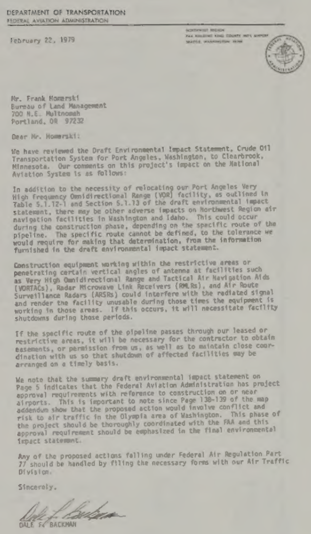
20



DEPARTMENT OF TRANSPORTATION
FEDERAL AVIATION ADMINISTRATION

February 22, 1979

Mr. Frank Homerski
Bureau of Land Management
700 N.E. Multnomah
Portland, OR 97232

Dear Mr. Homerski:

We have reviewed the Draft Environmental Impact Statement, Crude Oil Transportation System for Port Angeles, Washington, to Clearbrook, Minnesota. Our comments on this project's impact on the National Aviation System is as follows:

In addition to the necessity of relocating our Port Angeles Very High Frequency Omnidirectional Range (VOR) facility, as outlined in Table 5.1.12-1 and Section 5.1.13 of the draft environmental impact statement, 1 there may be other adverse impacts on Northwest Region air navigation facilities in Washington and Idaho. This could occur during the construction phase, depending on the specific route of the pipeline. The specific route cannot be defined, to the tolerance we would require for making that determination, from the information furnished in the draft environmental impact statement.

Construction equipment working within the restrictive areas or penetrating certain vertical angles of antenna at facilities such as Very High Omnidirectional Range and Tactical Air Navigation Aids (VORTACs), Radar Microwave Link Receivers (RMLRs), and Air Route Surveillance Radars (ARSRs) could interfere with the radiated signal and render the facility unusable during those times the equipment is working in those areas. If this occurs, it will necessitate facility shutdowns during those periods.

If the specific route of the pipeline passes through our leased or restrictive areas, it will be necessary for the contractor to obtain easements, or permission from us, as well as to maintain close coordination with us so that shutdown of affected facilities may be arranged on a timely basis.

We note that the summary draft environmental impact statement on Page 5 indicates that the Federal Aviation Administration has project approval requirements with reference to construction on or near airports. This is important to note since Page 138-139 of the map addendum show that the proposed action would involve conflict and risk to air traffic in the Olympia area of Washington. This phase of the project should be thoroughly coordinated with the FAA and this approval requirement should be emphasized in the final environmental impact statement.

Any of the proposed actions falling under Federal Air Regulation Part 77 should be handled by filing the necessary forms with our Air Traffic Division.

Sincerely,

Dale F. Backman
DALE F. BACKMAN

Belgrade, MT 59714

Bureau of Land Management
c/o State Director
Granite Tower, 222 N 32nd
Billings, MT 59101

To Whom it May Concern:

I would like to comment on the Northern Tier Pipeline project.

To build and bury a pipeline that will only last 20 years and then remove it seems absolutely absurd. The cost of such a project with the present rate of inflation could not possibly be practical. Trucking the oil across the country, crazy as it may sound, would not be as ludicrous as the Northern Tier Pipeline.

And last but not least, is the damage and potential to the land this pipeline will cross. Can NTP, Co. assure me that all the rivers it crosses will not be destroyed in those areas or that siltation damage downstream will not occur. Can NTP, Co. state that they will supervise every employee involved so there will be no littering, no driving off right of ways, no poaching of wildlife?

It seems likely that more than the 118 miles of agricultural land that it crosses will be destroyed; by construction, removal and oil spills. I consider the preservation of our already shrinking agricultural land more important than the transportation of oil.

I am against the construction of the Northern Tier Pipeline. To me, fresh water, wildlife and crop land are more important than the high price of oil.

Thank you for your time.

Sincerely,

Beth Youst
Beth Youst

City of Tacoma
WASHINGTON

DEPARTMENT OF PUBLIC UTILITIES

February 15, 1979

State Director
Bureau of Land Management
P. O. Box 2965
Portland, Oregon 97208

Gentlemen:

Draft Environmental Statement for
Crude Oil Transportation System

We have reviewed the subject statement as it relates to our water utility. The proposed pipeline alignment now avoids the City of Tacoma's Green River Watershed, the City of Seattle's Cedar River and Tolt River Watersheds, and the Spokane-Rathdrum Sole Source Aquifer. This is extremely important in our view because these water sources serve over 40 percent of the State's population. Additionally, these water sources rely only on watershed and aquifer protection and simple chlorination to produce high quality drinking water. An oil spill would be unacceptable due to the lack of conventional water treatment facilities for these water sources. The Northern Tier Pipeline Company has taken a responsible position in avoiding these major water sources.

1 The subject statement does not indicate what the long-term effects of an oil spill would be on a water system using only simple chlorination for treatment. We are concerned that parts per million and parts per billion concentrations of oil components would leach from a spill area for years. The resulting reactions with chlorine could cause taste and odor problems and health problems related to the formation of chlorinated hydrocarbons in the water supply. As long as the oil pipeline avoids the major State water sources, we think this question does not have to be addressed. If the alternate route through the Green River Watershed were chosen, this question would have to be adequately addressed.

The alternate route through the Green River Watershed is a poor choice in our view, especially since an oil spill could impact both our surface water diversion and our North Fork of the Green River aquifer.

Thank you for the opportunity to comment on this project. If you should have questions regarding our comments, please call Mr. Glenn Medervold at (206) 593-8212.

Very truly yours,

John A. Roller
John A. Roller
Superintendent

STATE OF WASHINGTON
Department of
Natural Resources

COMMISSIONER
BERT L. COLE

February 23, 1979

State Director
Bureau of Land Management
P.O. Box 2965
Portland, OR 97208

Dear Sir:

SUBJECT: Northern Tier Pipeline - Draft EIS

The DNR has reviewed the Draft EIS for the Northern Tier Pipeline proposal. In addition to the draft, we requested five sets of county maps (scale 1/2" = 1 mile) showing the proposed Northern Tier Pipeline route. These maps were sent to our respective area managers to determine the relationship of the proposed pipeline to lands managed by the DNR. In some instances, the pipeline and access roads will pass through DNR managed lands. In addition, the crossing of numerous water bodies is also of interest to DNR since this agency manages lands within beds of navigable waters, ie., rivers, lakes and marine.

DNR concerns Northern Tier should be aware of include the following:

①

1. Fire permits, fire tool and equipment requirements for operations on all state and private forest lands.
2. Forest Practice Applications on state and private lands.
3. Surface mining permits (off site borrow pits) on state and private lands.
4. Right of way on all public lands of the State of Washington.
5. Waiver of damages from leasees on DNR lands.
6. Extra requirements would be needed as the pipeline crosses irrigated lands.
7. Need to be advised ahead of work schedule prior to entering State land.

Obviously, as a State Land Management agency, the DNR has proprietary interest where such lands may be affected by pipeline activity. However, the DNR also has environmental concerns for those segments of pipeline that cross water ways, particularly marine waters, where we have aquaculture activities associated with marine plant life production and shellfish harvesting activities. There are potential problems from accidental breaks in a submerged pipeline crossing Puget Sound near those activities.

These are our primary comments at this time. If you have any questions, please contact Jerry Probst, Olympia, (206)753-5308.

Sincerely,

BERT L. COLE
Commissioner of Public Lands

Ralph A. Beswick
Supervisor

FEDERAL HIGHWAY ADMINISTRATION
REGION 5
18209 DIXIE HIGHWAY
HOMEWOOD ILLINOIS 60430

February 26, 1979

IN REPLY REFER TO:
HED-05

Bureau of Land Management
Oregon State Director
Northern Tier Project
Room 1250, Lloyd Building
700 N.E. Multnomah
Portland, Oregon 97232

Gentlemen:

The draft EIS for the Crude Oil Transportation System, Port Angeles, Washington to Clearbrook, Minnesota has been reviewed.

The draft EIS, on page 3-106, discusses the impacts to road and highway networks. This section indicates that there will be some road damage due to heavy truck traffic and pipeline construction, and some congestion as a result of the construction traffic. The draft EIS also recognizes that permits will be required from Transportation Agencies.

① In order to minimize these impacts, it is recommended that close coordination be maintained with the State and local Transportation Agencies to establish acceptable road crossing construction methods and to insure traffic safety through construction zones.

Sincerely yours,

Donald E. Trull
Regional Administrator

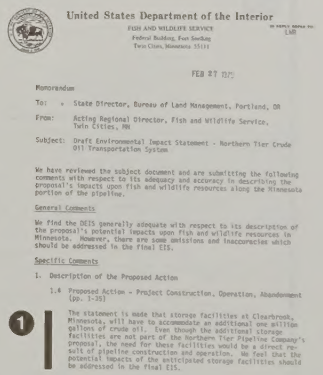
**25**



United States Department of the Interior
FISH AND WILDLIFE SERVICE
Federal Building, Fort Snelling
Twin Cities, Minnesota 55111

IN REPLY REFER TO:
LMR

FEB 27 1979

Memorandum

To: State Director, Bureau of Land Management, Portland, OR

From: Acting Regional Director, Fish and Wildlife Service, Twin Cities, MN

Subject: Draft Environmental Impact Statement - Northern Tier Crude Oil Transportation System

We have reviewed the subject document and are submitting the following comments with respect to its adequacy and accuracy in describing the proposal's impacts upon fish and wildlife resources along the Minnesota portion of the pipeline.

General Comments

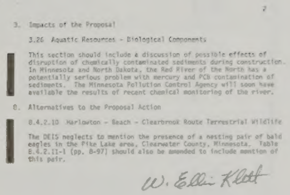
We find the DEIS generally adequate with respect to its description of the proposal's potential impacts upon fish and wildlife resources in Minnesota. However, there are some omissions and inaccuracies which should be addressed in the final EIS.

Specific Comments

1. Description of the Proposed Action

1.4 Proposed Action - Project Construction, Operation, Abandonment (pp. 1-35)

① The statement is made that storage facilities at Clearbrook, Minnesota, will have to accommodate an additional one million gallons of crude oil. Even though the additional storage facilities are not part of the Northern Tier Pipeline Company's proposal, the need for these facilities would be a direct result of pipeline construction and operation. We feel that the potential impacts of the anticipated storage facilities should be addressed in the final EIS.



2

3. Impacts of the Proposal

3.26 Aquatic Resources - Biological Components

② This section should include a discussion of possible effects of disruption of chemically contaminated sediments during construction. In Minnesota and North Dakota, the Red River of the North has a potentially serious problem with mercury and PCB contamination of sediments. The Minnesota Pollution Control Agency will soon have available the results of recent chemical monitoring of the river.

8. Alternatives to the Proposal Action

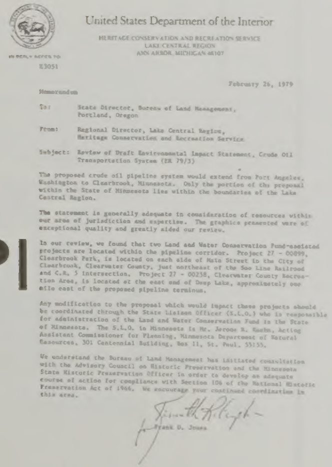
③ 8.4.2.10 Harlowton - Beach - Clearbrook Route Terrestrial Wildlife

The DEIS neglects to mention the presence of a nesting pair of bald eagles in the Pike Lake area, Clearwater County, Minnesota. Table 8.4.2.11-1 (pp. 8-97) should also be amended to include mention of this pair.

W. Ellis Klett

---

**26**



United States Department of the Interior
HERITAGE CONSERVATION AND RECREATION SERVICE
LAKE CENTRAL REGION
ANN ARBOR, MICHIGAN 48107

IN REPLY REFER TO:
E3051

February 26, 1979

Memorandum

To: State Director, Bureau of Land Management, Portland, Oregon

From: Regional Director, Lake Central Region, Heritage Conservation and Recreation Service

Subject: Review of Draft Environmental Impact Statement, Crude Oil Transportation System (ER 79/3)

The proposed crude oil pipeline system would extend from Port Angeles, Washington to Clearbrook, Minnesota. Only the portion of the proposal within the State of Minnesota lies within the boundaries of the Lake Central Region.

The statement is generally adequate in consideration of resources within our area of jurisdiction and expertise. The graphics presented were of exceptional quality and greatly aided our review.

① In our review, we found that two Land and Water Conservation Fund-assisted projects are located within the pipeline corridor. Project 27 - 00099, Clearbrook Park, is located on each side of Main Street in the City of Clearbrook, Clearwater County, just northeast of the Soo Line Railroad and C.R. 5 intersection. Project 27 - 00238, Clearwater County Recreation Area, is located at the east end of Deep Lake, approximately one mile east of the proposed pipeline terminus.

Any modification to the proposal which would impact these projects should be coordinated through the State Liaison Officer (S.L.O.) who is responsible for administration of the Land and Water Conservation Fund in the State of Minnesota. The S.L.O. in Minnesota is Mr. Jerome H. Kuehn, Acting Assistant Commissioner for Planning, Minnesota Department of Natural Resources, 301 Centennial Building, Box 11, St. Paul, 55155.

We understand the Bureau of Land Management has initiated consultation with the Advisory Council on Historic Preservation and the Minnesota State Historic Preservation Officer in order to develop an adequate course of action for compliance with Section 106 of the National Historic Preservation Act of 1966. We encourage your continued coordination in this area.

for Frank D. Jones

Portland, Oregon 97208

A review of the Draft Environmental Statement Crude Oil Transportation System, Port Angeles, Washington to Clearbrook, Minnesota (AS proposed by Northern Tier Pipeline Company) has been made by the Board of Commissioners, Clallam County Fire Protection District #3, P.O. Box 186, Carlsborg, WA. 98324.

Clallam County Fire Protection District #3 is a Political subdivision of the State of Washington. It is located in Clallam County, Washington. If the proposed crude oil transportation system becomes a reality, the on shore facility (Tank Farm) and some of the pipeline will be with in the boundries of the Fire Protection District.

The Board of Commissioners is composed of three resident electors of the District and represent the residents in the management of the Fire Protection District for the purpose of the elimination of fire hazards and for the protection of life and property outside of incorporated cities.

To assist the Bureau of Land Management and anyother interested party comments of each current Commissioner will be identified with his name to expedite inquiries.
Current Commissioners are:

J. Claud Courtier, Jr.

| | Item | Page | | Individual |
|---|---|---|---|---|
| ㉘ | 34 * | Ch. 2 | Generally the air quality addressed Port Angeles and the Olympic National Park. However the area to the East of the proposed port and on shore facility is ignored. Since the prevailing wind is from a Westerly direction considerable attention should be given to air quality to the East of the proposed facility. | Courtier |
| ㉙ | 35 | 2-44 | Par 2 As it relates to Fire Protection District #3 should read: Fire Protection District #3 which serves the Green Point area encompasses over 164 square miles It has a full time paid Chief and 80 volunteers. There are five Fire Stations, 6 Pumpers, 3 water tankers, 2 Aid Cars and a Chief's vehicle. It is rated 8 by the Washington Surveying and Rating Bureau. (The scale used is 1 to 10 with 10 being the lowest level of protection.) | Courtier |
| ㉚ | 36 | 2-44 | Par 3 is not accurate. Sequim has one Pumper, one Pumper belongs to Fire Protection District #3 is housed in the Sequim Fire Department. It is used by the Sequim Volunteer Fire Department to respond to fire in Sequim and in part of Fire Protection District #3 immediately around Sequim. | Schmuck |
| ㉛ | 37 | 2-115 | Par 8: The Dungeness River is not included but should be since it is an important salmon and steelhead spawning river as well as being the source of water for irrigating a large area. | Courtier |
| ㉜ | 38 | •2-133 | Par 3: Last sentance should read: In North Dakota there would be numerous Intercontinental Ballistic Missile (ICBM) Cable crossings. | Courtier |
| ㉝ | 39 | •2-156 | Par 1: Reference is made to U.S. 101 and figure 2.1 1.13-1 (page 2-33) Figure 2.1.1.13-1 does not depict the fact being verbalized. | Courtier |
| ㉞ | 40 * | 5-1 | Par 5 Since there would be an unavoidable increase on $SO_2$ over the Port Angeles area for such a short period of time does this mean the downwind area will have the $SO_2$ most of the time?<br>It is recommended that scrubbers be required to capture the $SO_2$. | Courtier |
| ㉟ | 41 | 5-2 | Generally the Air quality with respect to particulates $SO_2$, $NO_x$ and $O_3$ address the Port Angeles area and ONP. The area to the East which is down wind of the proposed sites should be considered in more detail. | Courtier |
| ㊱ | 42 | •5-2 | Par 10 odor: Odors related to the on shore facility are not addressed. It is assumed odors will be similar to other crude oil facilities. If this is so the problem must be delt with. | Schmuck |
| ㊲ | 43 | 5-9 | Table 5.1.12-2 Added to the possible impacts column should be a statement that reads essentally: : Oil | Courtier |

| | Item | Page | | Individual |
|---|---|---|---|---|
| | | | froth caused by water turning to steam in the oil could cause wide spread damage." Water changing to steam expands in excess of 1,500 to 1. 1 gallon of water makes in excess of 1,500 gallons by volume of steam under normal atmospheric pressures water changes to steam in crude and heavy oils results in a froth wave that engulf structures, people and stock. It is adhesive and can be hot enough to cause burns on flesh. | |
| | 44 | 5-12 | Table 5.1.15-1 Unavoidable impacts: Fire Protection during operation: In addition to straining local departments residents in the Green Point area would be greatly inconvienced by Fire Fighting activities, spectators, New media and from the smoke, ~~[illegible]~~ and possibly oil froth. Residents with shore property that permits a view of the Green Point area would undoubtedly be bothered by the Press and Television News people seeking spectacular photo. coverage of any major fire or explosion. | Courtier |
| | 45 | •5-16 | Par 8 and 9 It appears that if it will take up to 20 years for complete recovery of a destroyed salmon population, they might as well be written off as lost. | Courtier |
| | 46 | •6-2 | Par 7 With respect to the Bald Eagles. The author of the DES may know of alternative habitat being available nearby, but how do we tell the Bald Eagle that? | Courtier |
| ㊳ | 47 | 6-4 | Par 4 Air quality for the inhabited area East of the proposed Port and On Shore Facility is not considered since that area is downwind a carefull analysis should be made. | Courtier |
| | 48 | •8-3 | Par 2 and 3 Clallam County to the East of the proposed site at Green Point is similar to Burrows Bay in that it has neglegable industry and has important Marine and terrestrial resources and like Freshwater Bay the area has relatively little developement. It is believed the impacts at Port Angeles and Green Point would be equal to or greater than the impacts at Burrows Bay or Freshwater Bay. | Schmuck |
| | 49 | 8-5 | Par 14 If Alaskan Crude spilled at Long Beach would cause critical environmental impacts it is believed the same spill at Port Angeles, Green Point or along the pipeline in Clallam County and Jefferson County would be devistating. | Schmuck |
| ㊴ | 50 | •8-10 | Since the down wind area was considered for Cherry Point the leeward side of Port Angeles and Green Point should also be considered. | Courtier |

| | Item | Page | | Individual |
|---|---|---|---|---|
| ㊵ | 51 | 8-12 | Par 4 If a spill were to have an impact on the nearly level and fertile land in the Cherry Point area, it is more than probable that a spill in anyone of the irrigation ditches or in the Dungeness River would have an impact on fertile farm land in Clallam County. | Schmuck |

While the DES is an impressive document it appears that there is much more research needed before the final environmental statement is completed.

The Board of Commissioners for Fire Protection District #3 are intensly interested in all safety, social and other fragments of the propsed system. If it must be in or transit Fire Protection District #3 it is their wish to have a system that is safe now and will continue to be that way.

March 1, 1979

Having come across your article with an address to write to, I decided for once I wanted to have my feelings known.

I am a homemaker, having a husband and three teenage children, live in a small home. I am for environment protection, clean air and water. But I think the time has come for compromise between the Federal and State governments. People in the northern part of this country have always had to pay more for every thing. Just because we live where we do. With a pipeline in this region we wouldn't have to depend on other countries. Canada has cut back on our fuel, so that leaves the greedy Arab countries. They have forgot who put them in the position they are in now. If it hadn't been for this countries money they wouldn't have the technology they have today. I don't say we should get oil for nothing, but why blood us and others to death.

When we have refineries up here it is crazy to not have our own supply of oil brought in to this region by a pipeline. This country better start looking out for its own people. People are feed up with being taken for a ride. People will conserve, but they better now be lied to any more. We are feed up with a few people making decisions that cost us middle class people more money every time we go for food, heating oil, utilities. Some of us have to work without cost of living raises. We can't increase our wages when we feel like we need more money each month.

We need a pipeline here and the people against better decide if they can heat their homes, businesses, farms and equipment on fuel or pride.

2.

For they may find themselves with nothing. We will see how long this keeps them warm when it gets -50 below zero. The Federal and State Officials should be able to work together for the people of this region for one time. This pipeline will help this whole country also.

My letter will probably be filed in the unimportant, but at least I had my say. Even if I am just a homemaker that had to go find a part time job to help offset the cost increases every week. It use to be every month, now it is every day and week.

Thank you for taking the time from your busy job to let me put my feeling on paper.

Sincerely Yours,
Mrs. Rodney L. Anderson

Gentlemen:

This is in regard to your hearing in Billings, March 6, on the Northern Tier Pipeline.

I am unable to be there, but will appreciate having this letter entered into the record.

Our newspaper favors the project very strongly, and I am confident that we reflect the attitude of the great majority in our area on this.

Many miles of the pipeline will go through an area served by our newspaper, and we have heard no opposition expressed to the pipeline. We have, however, heard much said for it.

The need for this pipeline to Montana is vital as much of our source of crude oil from Canada is being cutoff.

Also, the international situation on crude is very serious for the United States and the entire area to be served by the Northern Tier Pipeline. So it seems very important that we make our Alaskan oil available just as quickly as possible.

Respectfully yours,
Ken Byerly

STATE INTERGOVERNMENTAL CLEARINGHOUSE SUPPLEMENTARY "LETTER OF COMMENT" ON PROJECT REVIEW IN CONFORMANCE WITH OMB CIRCULAR NO. A-95

To: Bureau of Land Management, Oregon State Office

STATE APPLICATION IDENTIFIER: 7901119034

Mr. Frank Hamerski, Acting Project Manager
U.S. Dept. of Interior
Bureau of Land Management - Oregon State Office
P.O. Box 2965
Portland, Oregon 97208

Dear Mr. Hamerski:

Subject: Draft Environmental Impact Statement for the Crude Oil Transportation System.

This Draft EIS was received in our office January 11, 1979.

The above referenced draft EIS has been reviewed through the North Dakota State Intergovernmental Clearinghouse in compliance with Office of Management and Budget Circular No. A-95 and/or North Dakota Executive Order No. 48. Previous comments were forwarded to you with a "Letter of Comment ", dated January 15, 1979 and "Supplementary Letter of Comments' dated February 22 and 26, 1979.

Since then, additional comments have been received from the North Dakota Soil Conservation Committee.

This letter and the attached comments constitute the further comment of the State Intergovernmental Clearinghouse. To further document your compliance with Office of Management and Budget Circular No. A-95, this letter, the attached comments and your response to those comments should be made a part of your development proposal.

Please use the above SAI number for reference to the above project with this office. Your continued cooperation in the review process is much appreciated.

Sincerely yours,

Bonnie A. Banks/aj

NORTH DAKOTA STATE SOIL CONSERVATION COMMITTEE

March 1, 1979

Mrs. Bonnie Banks, Associate Planner
State Planning Division
State Capitol
Bismarck, ND 58505

Dear Mrs. Banks:

We have reviewed the Draft Environmental Impact Statement on the Crude Oil Transportation System as proposed by Northern Tier Pipeline Company and submit the following comments.

❶ We recommend the following suggestions (not otherwise addressed) be considered during pipeline construction:

- To save, segregate, and respread all topsoil and subsoil on crop and rangeland during construction of the pipeline based on a soil survey, if available.
- That weed control measures be incorporated in all phases of pipeline construction.
- That special emphasis be given to critical areas where erosion potential is greatest.
- If encountering areas of heavy claypan soils where landowners use deep tillage operations (2 to 3 feet depth), the pipeline should be buried at a sufficient depth needed for proper protection.

We suggest that mainline valves and other surface structures that are located on privately owned land be situated in areas that least affect local farm and ranch operations.

Sincerely,

STATE SOIL CONSERVATION COMMITTEE

Gary L. Puppe
Executive Secretary

700 N. E. Multnomah
Portland, Oregon 97232

Gentlemen:

As an influential part of this business community of Williston, North Dakota, and its area, you can expect our full support of the Northern Tier Pipeline Project.

As the energy crisis becomes more serious day by day, we consider the pipeline project to be a No. 1 priority. We believe a "step-up" in the development of the United States oil resources to be all important, and the transportation of oil, after it is brought out of the ground, is one of the most important factors in the overall picture of national security.

It is our firm belief that the sooner this nation gets down to "brass tacks" in the devlopment of its own vast oil resources, the sooner we will whip the energy crisis which faces us.

The security of this nation, the maintaining of peace in the world, and our country's economic structure all rest on the action taken in projects such as yours.

Sincerely,

Carl R. Larson

700 N.E. Multnomah St.
Portland, Oregon 97232

Gentlemen:

I wish to go on record in support of the Northern Tier Pipeline as it is presently presented. I am a citizen of Montana and plan to spend the rest of my life in Montana. I plan to marry and raise my family in Montana. Therefore, it is a concern to me to be able to find employment in this state in which to raise a family. The Northern Tier Pipeline, as I see it, will give me a greater opportunity for a job to support my family.

Moreover, I feel that the proposed pipeline is the most economical means of shipping the Alaskan crude oil to the midwest. It is my understanding that the high percentage of the oil used by our refineries comes from Canada and that Canada will not guarantee its supply of oil in the future. Therefore, I'm in full support of the Northern Tier Pipeline.

Sincerely,

Lee Vanica
Laborer, Local 98

NORTH DAKOTA STATE HIGHWAY COMMENTS
ON DRAFT EIS: CRUDE OIL TRANSPORTATION
SYSTEM (AS PROPOSED BY THE NORTHERN TIER
PIPELINE COMPANY)

February 21, 1979

On pages 3-107 and 3-108, it is stated that there is a potential for significant road damage during the construction phase of the pipeline. We concur in that assessment since local road systems, particularly structures, are inadequate to carry heavy construction loads and traffic.

To minimize the impact on roads, it will be necessary to initiate a comprehensive program of planning, coordination and review for improvements, repair and maintenance of state, county and local roads affected by construction and operations of the pipeline.

❶ U.S. Highway 2 has been relocated from the Williams-Mountrail County Line easterly to 5 miles east of the Ward-Mountrail County Line. A map showing the new location is attached.

U.S. Highway 2 across the entire state is being reconstructed to provide a four lane facility. Since the pipeline follows much the same corridor as U.S. Highway 2, there is a potential for conflicts in location.

❷ It is recommended that the mitigating section include commitments for:

1. Detail review and coordination of final design pipeline plans to avoid conflicts with future highway construction.
2. Restrict contractor hauling to designated construction haul roads. State & local officials must be consulted and given an opportunity for review and comment.
3. Provisions for restoration of haul roads either in construction contracts or by agreement with state and local officials.

9 March 1979

Bureau of Land Management
Northern Tier Project
Room 1250 Lloyd Building
700 N. E. Multnomah
Portland, Oregon 97232

Dear Sirs:

I presented oral testimony at the BLM draft Northern Tier Pipeline EIS Hearing in Missoula, Montana on March 8, 1979. At that meeting, I said that I would also be submitting a written statement. Enclosed is one copy of my written comments on BLM's Draft Northern Tier EIS.

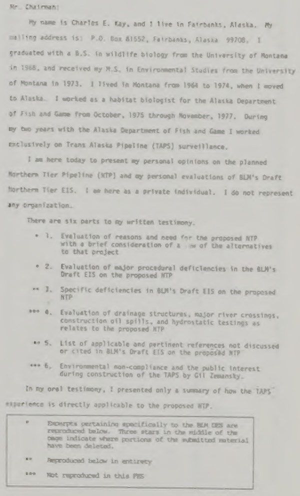
I am,

Sincerely yours,

Charles E. Kay

Charles E. Kay

CEK:e'h



Mr. Chairman:

My name is Charles E. Kay, and I live in Fairbanks, Alaska. My mailing address is: P.O. Box 81552, Fairbanks, Alaska 99708. I graduated with a B.S. in wildlife biology from the University of Montana in 1968, and received my M.S. in Environmental Studies from the University of Montana in 1973. I lived in Montana from 1964 to 1974, when I moved to Alaska. I worked as a habitat biologist for the Alaska Department of Fish and Game from October, 1975 through November, 1977. During my two years with the Alaska Department of Fish and Game I worked exclusively on Trans Alaska Pipeline (TAPS) surveillance.

I am here today to present my personal opinions on the planned Northern Tier Pipeline (NTP) and my personal evaluations of BLM's Draft Northern Tier EIS. I am here as a private individual. I do not represent any organization.

There are six parts to my written testimony.

* 1. Evaluation of reasons and need for the proposed NTP with a brief consideration of a few of the alternatives to that project

* 2. Evaluation of major procedural deficiencies in the BLM's Draft EIS on the proposed NTP

** 3. Specific deficiencies in BLM's Draft EIS on the proposed NTP

*** 4. Evaluation of drainage structures, major river crossings, construction oil spills, and hydrostatic testings as relates to the proposed NTP

** 5. List of applicable and pertinent references not discussed or cited in BLM's Draft EIS on the proposed NTP

*** 6. Environmental non-compliance and the public interest during construction of the TAPS by Gil Zemansky.

In my oral testimony, I presented only a summary of how the TAPS experience is directly applicable to the proposed NTP.

* Excerpts pertaining specifically to the BLM DES are reproduced below. Three stars in the middle of the page indicate where portions of the submitted material have been deleted.

** Reproduced below in entirety

*** Not reproduced in this FES

### Reasons, Needs, and Alternatives

BLM is in error when they consider this proposal to be the Northern Tier Pipeline. What we really are discussing today is the Washington to Minnesota extension of the Trans Alaska Pipeline (TAPS) plus the Long Beach, California to Midland, Texas or SOHIO extension of the TAPS for the Northern Tier Pipeline Company (NTPC) has officially stated that their project is not in competition with the planned SOHIO pipeline. The TAPS was the wrong pipeline built to the wrong place and now the public is faced with the possibility of building two new crude oil distribution systems to aleviate the "surplus oil" situation that has been created on the West Coast by construction of the TAPS.

* * *

This historical ANS "surplus" oil perspective is important since we are in this position today because National decisions were based on figures supplied by the oil companies. ① In the BLM's Draft EIS on the proposed Northern Tier Project, BLM states that the two overriding considerations in their review of the Northern Tier extension of the TAPS are: 1) ANS oil "surplus" on the West Coast, and 2) shortfall or lack of oil in the Northern Tier states. The only "surplus" or shortfall figures that BLM presents were compiled by oil companies or with company consultants. BLM does not present any independent analysis of "surplus" or shortfall. The American people believed the oil companies once and we are here today. Why should the American public now believe these new estimates from these oil companies? Why has BLM not developed a totally independent evaluation of the ANS "surplus" problem?

BLM estimates that there is currently a "surplus" of 500-600,000 bpd on the West Coast. BLM does not mention the fact that during the first four months of 1978 624,300 barrels per day of foreign crude oil were imported to this same West Coast.

> It was considered that the Valdez terminus could free the Pacific district from foreign imports and yet in the first 4 months of 1978 the Pacific district imported 624,300 barrels of crude daily. Few steps were taken to modify existing refinery capacity to accept North Slope oil with its relatively high sulphur content. As a result, the Pacific district continues to import foreign crude while North Slope production is deemed surplus.
>
> Shannon Wall, President
> National Maritime Union of America (54)

How can we be importing over 600,000 bpd of foreign crude oil to the West Coast at the same time BLM would have us believe there is a "surplus" of 500,000 bpd of ANS oil on the same West Coast? The oil refineries on the West Coast import foreign crude oil in part because those refineries are not designed to refine ANS oil. Oil is not oil is not oil. An oil refinery is designed to process a particular type of crude oil based on the specific gravity and sulfur content of the crude. The ANS oil is called a sour crude because it has a sulfur content slightly above one percent.

* * *

However, retrofitting West Coast oil refineries to process the ANS oil is a viable alternative to the proposed NTP.

* * *

② If the oil refineries on the West Coast were retrofit to process the ANS oil, this would alleviate the "surplus" on the West Coast and at the same time over 600,000 bpd of foreign oil would not have to be imported to that region. In their Draft NTPC EIS, BLM does not discuss this alternative. NTPC officials have publicly stated that the estimated construction cost of their proposed project is approximately 1.8 billion dollars. How much would it cost to retrofit the oil refineries on the West Coast so that they could process all of the "surplus" ANS? I believe that BLM should undertake a complete analysis of retrofitting as a solution to the "surplus" ANS on the West Coast.

③ The Northern Tier Pipeline Company states that because of scheduled curtailments of Canadian crude oil into the Northern Tier states there will be a shortfall of crude oil in that region during the 1980's. In the BLM draft EIS on the proposed Northern Tier Pipeline, the only data BLM presents on "anticipated" or "estimate" shortfall was again, developed by oil companies, or oil company consultants. BLM does not present any independent analysis of projected shortfall in the Northern Tier states. During debate on the TAPS, the government accepted oil company data that said there would be no "surplus" on the West Coast. We now have the Alaskan Pipeline and the refineries on the West Coast cannot use ANS oil. It is logical to ask which specific oil refineries in the Northern Tier states will buy exactly what volume of oil from the Northern Tier Pipeline for how long. What refineries have signed agreements to purchase oil transported through the proposed Northern Tier Pipeline? This is a critical consideration. BLM should present the public with data that shows exactly which oil refineries in the Northern Tier states have agreed in writing to purchase exactly how much ANS oil and have it delivered to their refineries by the proposed Northern Tier Pipeline. If BLM or the oil refineries cannot or will not do this, I then suggest that there is absolutely no need for the Northern Tier Pipeline Project.

④ Another alternative that BLM fails to address is the abandonment of the TAPS. The TAPS from Delta Junction to Valdez could be abandoned and a new 48" oil pipeline built from Delta Junction down the Alcan Highway into the Midwest states where BLM tells us the ANS oil is now needed. This is the route originally favored by various environmental groups during the congressional debate on the TAPS in the early 1970's. The U.S. and Canada have already agreed to construct a large diameter natural gasline down this corridor[1] and the two pipelines could be built together off of the same right-of-way. The U.S. has a Hydrocarbon Transport Treaty with Canada that guarantees uninterrupted flow of U.S. gas or oil through any pipeline constructed in Canada. This alternative would eliminate the TAPS Valdez terminal and all TAPS generated tanker traffic. This would protect the Alaska, British Columbia, Washington, Oregon, California, Mexican, and Central American coasts from being impacted by a catastrophic oil spill that will occur when there is a tanker accident. I recommend that BLM conduct a detailed evaluation of this method of handling the problem of "surplus" ANS oil. This alternative would eliminate any need for either the Northern Tier Pipeline or the SOHIO Pipeline.

⑤ BLM also fails to present a complete analysis regarding shipment of ANS oil to the Gulf States. There is no "surplus" of ANS oil on the West Coast. BLM's "surplus" figure of 500-600,000 bpd ANS oil is not accumulating on the West Coast. The "surplus" oil isn't sitting off of the West Coast in tankers nor is it being stored on the West Coast. BLM's "surplus" ANS oil is currently being shipped to Gulf Coast ports where it is offloaded and distributed into the middle United States via the numerous pipelines which serve that region. ANS oil is presently reaching oil refineries in Minnesota and Chicago via the existing pipeline systems. This is part of the reason why the large refineries in the Midwest have not supported the Northern Tier Pipeline. Those oil refineries are presently obtaining ANS oil at a similar cost through the Gulf states. Furthermore, other pipeline companies are proposing to build additional pipelines from the Gulf area into Minnesota to transport more ANS oil into that region. These other pipeline proposals are in direct competition with the planned Northern Tier Project and they are the reason the State of Minnesota has denied a Certificate of Need to the NTPC. Yet, BLM in their Draft EIS fails to present more than a cursory analysis of this alternative. A recently released Department of Energy (DOE) study has concluded that for the NTPC to be economically viable, the NTPC must sell most of its throughput in the Minnesota to Chicago market. DOE states that approximately 1/2 of NTPC throughput would have to compete in the Chicago market. This region is presently served by numerous pipelines that start in the Gulf States. The NTPC, to be economically viable, must compete in an area served by an array of other pipeline companies. It is my opinion that BLM should undertake a comprehensive study of the utilization of mid-continental pipeline systems to transport ANS oil to determine if the NTPC could compete in that market.

⑥ A fourth alternative to the proposed NTP that BLM does not consider involves reducing the throughput of the TAPS down to the level that can presently be utilized on the West Coast.

* * *

In conclusion to this portion of my testimony, I believe that the United States and the American public need a comprehensive National Energy Policy before any pipeline project is approved by the Federal Government. The question of how to best utilize our ANS oil should be considered in its entirety not on a peacemeal SOHIO here NTPC there basis. We are here today because National Energy decisions were formulated and promoted by oil companies not in the true national interest, but in the name of company profit. I believe it is time for the public and our elected representatives to decide what is best for ourselves and not have this function performed for us by oil companies.

### ⑦ Major Deficiencies in BLM's Draft EIS on the Proposed NTP

30 U.S.C.A. Section 185 of the Mineral Leasings Act is the federal law that applies to rights-of-way for pipelines through public lands. Subsection (d) in width limitations states:

> The width of a right-of-way shall not exceed fifty feet plus the ground occupied by the pipeline (that is, the pipe and its related facilities) unless the Secretary or agency head finds and records the reasons for his finding, that in his judgment a wider right-of-way is necessary for operation and maintenance after construction, or to protect the environment or public safety. Related facilities include but are not limited to valves, pump stations, supporting structures, bridges, monitoring and communication devices, surge and storage tanks, terminals, roads, airstrips and campsites, and they need not necessarily be connected or contiguous to the pipe and may be the subjects of separate rights-of-way.

In BLM's draft EIS on the proposed Northern Tier project, BLM states that the NTPC has requested a temporary right-of-way 90 feet wide for construction and a permanent right-of-way width of 75 feet. Under 30 U.S.C.A. 185 (d) the Secretary of the Interior or the head of the BLM must record his reasons for permitting a right-of-way greater than 50 feet plus the ground occupied by the pipeline which in this case is approximately 54 feet. In their draft EIS, BLM does not present any reasons to support NTPC's request for right-of-way widths of 75 feet permanent and 90 feet temporary. As I understand this law, the head of the BLM or the Secretary of the Interior must submit a detailed report specifying why the NTPC should be granted a right-of-way greater than 54 feet. I hereby respectively request this report from the BLM since this report is not presented in their draft EIS. In this regard, it must be remembered that Alyeska's federal grant of right-of-way for the TAPS was limited to 54 feet (1). I believe that the question that BLM must adequately address is Why does the NTPC require a 90-feet temporary and 75 feet permanent right-of-way when Alyeska constructed the TAPS on a Federal right-of-way of 54 feet.

30 U.S.C.A. 185 (h) states:

> Environmental Protection
>
> ⑧ (h) (1) Nothing in this section shall be construed to amend, repeal, modify, or change in any way the requirements of section 4332(2) (C) of Title 42 or any other provision of the National Environmental Policy Act of 1969.
>
> (2) The Secretary or agency head, prior to granting a right-of-way or permit pursuant to this section for a new project which may have a significant impact on the environment, shall require the applicant to submit a plan of construction, operation, and rehabilitation for such right-of-way or permit which shall comply with this section. The Secretary or agency head shall issue regulations or impose stipulations which shall include, but shall not be limited to: (A) requirements for restoration, revegetation, and curtailment of erosion of the surface of the land; (B) requirements to insure that activities in connection with the right-of-way or permit will not violate applicable air and water quality standards nor related facility siting standards established by or pursuant to law; (C) requirements designed to control or prevent (i) damage to the environment (including damage to fish and wildlife habitat), (ii) damage to public or private property, and (iii) hazards to public health and safety; and (D) requirements to protect the interests of individuals living in the general area of the right-of-way or permit who rely on the fish, wildlife, and biotic resources of the area for subsistence purposes. Such regulations shall be applicable to every right-of-way permit granted pursuant to this section, and may be made applicable by the Secretary or agency head to existing rights-of-way or permits, or rights-of-way or permits to be renewed pursuant to this section.

It is my opinion that BLM's draft NTP EIS does not comply with these provisions of the federal law. This portion of the federal pipeline right-of-way law states that the Secretary of Interior or head of the BLM must issue regulations or impose stipulations that shall be formulated to insure the adequate protection of the environment. BLM does not discuss any such regulations and I have not found any such regulations in the Federal Register. BLM does not discuss or present any preliminary stipulations that BLM would place on the proposed NTP.

* * *

30 U.S.C.A. 185 (l) permits the federal government to have continuous surveillance on the proposed Northern Tier Pipeline.

> Reimbursement of Costs
>
> (l) The applicant for a right-of-way or permit shall reimburse the United States for administrative and other costs incurred in processing the application and the holder of a right-of-way or permit shall reimburse the United States for the cost incurred in monitoring the construction, operation, maintenance, and termination of any pipeline and related facilities on such right-of-way or permit area and shall pay annually in advance the fair market rental value of the right-of-way or permit, as determined by the Secretary or agency head.

Under this provision of the federal pipeline right-of-way law, the NTPC would have to pay for all federal government monitoring and surveillance on their proposed project as Alyeska was required to do on the TAPS. This is another reason why the TAPS experience is directly applicable to the proposed NTP.

* * *

On the applicability of the TAPS experience to the proposed NTP, I would like to quote from an Alaska Pipeline Office (APO) Trans-Alaska Pipeline Overview Study that was prepared by Mechanics Research, Inc. in 1977. This is the official position of the Department of Interior's Alaska Pipeline Office.

> Stipulations for future projects should reflect the experience concerning mitigation of environmental impact gained during the construction and early operational phases of the Trans-Alaska Pipeline System. Experience gained in such potential problem areas as revegetation and rehabilitation, slope failures, icing due to disturbance of water flow, protection of wildlife, erosion control, etc., should be incorporated into the environmental and technical sections of the Stipulations. (40)

There were four years of continuous government surveillance by engineers and biologists during construction of the TAPS. There are scores of official documents evaluating the construction impacts and mitigation measures that were observed on the TAPS. There are thousands upon thousands of internal governmental memos and reports relating to the TAPS. In BLM's Draft NTP EIS there is not one mention or reference to any of the knowledge, experience or data that was gained on the Alaska project. BLM's total absence of the TAPS experience is even more unexplainable when one realizes that the BLM office in Portland which wrote the NTP Draft EIS had former Alaska Pipeline Officials on their staff. To assist BLM with their evaluation of the proposed NTP, I have included a list of 59 applicable documents for BLM's consideration. As part of my written testimony, I have also presented BLM with a copy of Mr. Gil Zemansky's publication entitled Environmental Non-Compliance and the Public Interest During Construction of the Trans Alaska Pipeline.

A large diameter natural gas pipeline is to be built from Prudhoe Bay down the TAPS corridor to Delta Junction where that gas line will turn to the east and proceed down the Alcan Highway through Canada and into the Midwest states. The state of Alaska and the federal government have profited from the TAPS experience in their formulation of stipulations for this gas line project. ⑨ The state of Alaska and the federal government have analyzed the TAPS experience, evaluated what worked, what didn't work, and why and then they used this knowledge to develop a more comprehensive set of stipulations under which the gas line will be built. (3) Alaska has even developed entirely new Social Economic stipulations that the state will impose on the Northwest Gas Company to reduce the adverse social and economic impacts that would otherwise accompany gas line construction. In short, the government in Alaska has utilized the TAPS example to design their next pipeline project so that the pipeline will produce fewer adverse impacts. The question that BLM must answer is why has BLM not followed a similar course of action in their evaluation of the proposed NTPC?

---

[1] On September 22, 1977, pursuant to the Alaska Natural Gas Transportation Act of 1978, 15 U.S.C. 719, et seq., the President issued his Decision and Report to Congress on the Alaska Natural Gas Transportation System. In that Decision, the President designated a Northwest Energy subsidiary to construct and operate the Alaskan portion of the Alaskan Gas Project. On November 2, 1977, the President's Decision was ratified by Congress, and on December 16, 1977, the FERC issued a conditional certificate of public convenience and necessity (which is presently held by Alaskan Northwest Gas Transportation Company) authorizing the construction of facilities identified by the President. On July 4, 1977, the National Energy Board of Canada issued its Reasons for Decision, Northern Pipelines, and subsequently on April 4, 1978, subsidiaries of Foothills (Yukon) were issued Certificates of Public Convenience and Necessity by the Parliament of Canada under the provisions of the Northern Pipeline Act.

34 CONT

* * *

I have reviewed NTPC's preliminary Construction Management Procedures and they do not appear to be conducive to a meaningful Quality Control Program. As was experienced during installation of the TAPS, quality control would be given a role subserviant to pipeline construction. NTPC's proposed Quality Control program is inferior to Alyeska's Quality Control. If the NTPC is permitted to build their project, I recommend:

1. QC/QA lease conditions and stipulations similar to those on the TAPS, but with certain modifications including a specific provision for adequate environmental QC.
2. Government review and approval of QC/QA manual, QC/QA personnel qualifications, and a QC/QA training program before any construction begins; with absolutely no exceptions.
3. QC/QA be totally independent of the Execution Contractor's or Construction Management's control or supervision.
4. QC/QA have stop work authority so that they are able to halt construction that is non-compliance.

Quality Control is one of the most important parts of any construction project. It does no good to have the best environmental stipulations, best welding procedures, technical specifications and the like if these are not enforced by a Quality Control Program. Without proper quality control procedures, adequate QC staff, QC independence, and QC stop work authority other regulations are ineffective and meaningless.

* * *

In this regard, it should also be remembered that four major oil spills occurred in the first month of operations of the TAPS; a pipeline that was supposedly designed, engineered and built not to leak once in its 30 year projected lifeline. During start-up, APSC experienced a human error coupled with a design failure as the crude oil reached pump station #8 that caused an explosion which completely destroyed the pump building. At pump station #9, a different design failure-human error problem resulted in the shutdown of that pump station when crude oil flooded the pump building and flowed out of the door. On the north slope, a front-end loader operator back-filling around check valve #7, struck a 3 inch bypass pipe on that check valve and approximately 50,000 barrels of crude oil escaped to cover the tundra. One month later, crude oil was discovered in Washington Creek north of Fairbanks. Upon investigation, APSC discovered that the bolts on check valve #64 had never been properly tightened and that 50 to 150 barrels of oil per day had leaked out of the TAPS undetected for 30 days until that oil was discovered in Washington Creek. How would BLM prevent similar situations from occurring if the NTPC is permitted to build their project?

It is my position that these examples clearly demonstrate that BLM should conduct a complete analysis of the TAPS data, knowledge and experience to determine what worked, what didn't work, and why. A thorough evaluation of the TAPS example is necessary to insure that adequate technical and environmental stipulations are formulated for any future pipeline construction project. Government surveillance on the TAPS should be carefully reviewed to guarantee that the mistakes of the past are not perpetuated into the future. The Department of Interior's Alaska Pipeline Office did an unsatisfactory job of enforcing Alyeska's compliance with the TAPS stipulations in part because APO's philosophy was "we are helping APSC build this pipeline" instead of "we are here to insure compliance with technical and environmental stipulations." APO disregarded environmental protection during construction of the TAPS to speed pipeline construction. APO engineers were in the position of authority and the biologists were only advisors.

Near the end of construction on the TAPS, JFWAT biologists were elevated to positions of authority and only then were long standing environmental problems given the attention that was mandated by the U.S. Congress when they passed the TAPS stipulations into law. On any future construction projects, biologists should be in positions of authority and not subservant to engineers. The Alaska Pipeline Office developed such an unfavorable reputation that APO will not perform government surveillance on the natural gas line that is to be built from Alaska through Canada

CONT

and into the Midwestern United States. An entirely new surveillance team is being organized for gas line monitoring based on the lessons that were learned on the TAPS project.

Montana's Senator John Melcher has repeatedly stated that he doesn't want the NTP project to turn into another Alaska pipeline. I agree with Senator Melcher, I would hope that Montana's environment would be accorded a much higher degree of protection than the inadequate protection that was extended to Alaska's resources. While I was working on TAPS surveillance, I never thought that I would be attempting to raise a pipeline company up to the standards of Alyeska, but this is the position I find myself in today.

10

BLM has not proposed any pipeline right-of-way lease conditions, technical stipulations, environmental stipulations, quality control or government surveillance in their draft EIS on the NTP. I contend that BLM must adequately address all these considerations to fulfill BLM's obligations under the National Environmental Policy Act and 30 U.S.C.A. 185 of the Mineral Leasing Act.

In conclusion, BLM states on page 4-1 of their Draft NTP EIS:

> Presently available information on the proposal described the pipeline route in terms of a 2-mile-wide corridor. The port and onshore storage facilities are described in terms of initial design specifications. This information is not sufficiently detailed to identify and quantify most site specific impacts. Federal, state, and local agencies generally require more specific information on proposed locations, design of system components, construction, and reclamation methods, and operating procedures to determine what mitigating measures would be required under existing regulations and codes. Similarly, private landowners need more site specific details about the proposal in order to determine what measures they would require as easement provisions.

BLM says that at this time they cannot delineate specific impacts that would be created by the proposed NTP because that project has not been adequately defined. Why then has BLM issued a Draft EIS when BLM admits they do not know what the impacts will be? The purpose of an EIS is to allow for a detailed evaluation and comparison of all the specific impacts that would be generated by any proposed project. Since BLM says they cannot yet define the specific impacts of the Proposed NTP, I question BLM's compliance with the provisions of the National Environmental Policy Act.

In these review comments, there are frequent references to the Trans Alaska Pipeline System (TAPS). The TAPS is used as an example because it involved construction of a large diameter pipeline similar to the proposed Northern Tier Pipeline. On the TAPS, there was continuous government surveillance by biologists and engineers during all phases of construction. These government monitors, through actual field experience, evaluated various mitigating techniques. Portions of this knowledge are applicable to any pipeline project.

Only those portions of the Draft BLM Northern Tier Pipeline EIS pertaining to Montana were reviewed.

Chapter 1. Description of the Proposed Action.

11

Page 1-3 and 1-4. "Projected Supply and Demand."

All the BLM figures on projected supply, demand, and shortfall within the Northern Tier States were estimated by oil companies or consultant firms working for oil companies. It must be remembered that when the oil companies were seeking passage of the Trans Alaska Pipeline Authorization Act (Public Law 93-153), the oil companies assured the U.S. Congress and the American people that if they were allowed to build their Alaskan pipeline there would not be a surplus of that Alaskan oil in the U.S. West Coast. Now these same oil companies are stating that there is a surplus of Alaskan oil on the West Coast, there will be an oil shortfall in the Northern Tier States, and in the "National Interest and Energy Selfsufficiency" the oil companies must now build a new 1557 mile crude oil pipeline. As a minimum, BLM should retain their own experts and formulate projected oil supply, demand and shortfall totally independent of oil company influence.

CONT

11

On page 1-4 BLM states, "The West Coast surplus is estimated to be about 500-600 thousand barrels per day (bpd) for 1978 (out of 1.2 million bpd ANS (Alaskan North Slope) production) and to rise to about 1 million bpd by 1985." In Table 1.4-1 on page 1-7, BLM quotes NTPC as stating that at the initial throughput of 709,000 bpd, 53 percent or 375,770 bpd would be Alaskan oil; the other 47 percent would be foreign crude oil. There is supposed to be a 500-600,000 bpd surplus of Alaskan oil on the West Coast yet Northern Tier proposes to transport only 375,000 bpd.

At ultimate capacity, Northern Tier would move 930,000 bpd, if we make the unsupported assumption that the throughput increase from the initial phase, 709,000 bpd to the ultimate phase, 930,000 or 237,000 bpd increase would be all Alaskan oil, then at ultimate capacity Northern Tier could transport the present West Coast surplus of Alaskan oil. However, by 1985 there would be an additional 500-600,000 bpd of Alaskan crude oil reaching the West Coast. Another surplus of 500-600,000 bpd will exist on the West Coast and the Northern Tier Pipeline would be full and at ultimate capacity. Whatever the advantages of the Proposed Northern Tier Pipeline happen to be, it is obvious that this project would not solve the problem of surplus Alaskan crude oil on the West Coast.

Pages 1-7 to 1-16. On the Marine Terminal were not reviewed.

Pages 1-16 to 1-17.

There would be 624 miles of pipeline in Montana. Of this total 60.4 miles would be in the Flathead Indian Reservation, 35.0 miles on BLM administered lands, 19.3 miles in the Lolo National Forest, and 9.7 miles in the Helena National Forest.

Page 1-18.

Under "State of Montana", line 9, Bitterroot River is incorrect; it should be Little Bitterroot River. The Bitterroot River is south of Missoula, Montana, not near the Flathead Indian Reservation. See page 93 of Map Addendum.

Page 1-18.

DOT requires that RX's be buried a minimum of 48 inches below the depth of scour of a waterway. BLM states that the pipeline will be buried 48 inches below the depth of scour. How is depth of scour to be computed? NTPC also plans to use pipe of increased wall thickness at all RX's.

Most of mainline is either .344" (40"OD) or .375" (42"OD).

| | Wall Thickness | Total Length |
|---|---|---|
| | .469" | 3.78 mi. |
| | .500" | .26 mi. |
| Total RX (NTPC Data) | .562" | .32 mi. |
| | .625" | 1.48 mi. |
| | .638" | .09 mi. |
| | 1.000" | .49 mi. |

BLM states that the RX pipe will be either concrete coated or that river weights will be utilized to keep the pipe from floating to the surface. How are RX's to be installed? At what time of year will the RX's be installed? On the TAPS a fish stream list was developed that set "windows" for allowable or permitted in stream work for each fish stream that was crossed by that pipeline.

Pages 1-21 and 1-22. RX's in Montana.

NTPC lists 25, but no data is provided on the size of each river and RX, depth of scour, depth of pipe below river bottom, etc.

Page 1-22.

NTPC lists 136 minor stream crossings in Montana. What is the size of each? How will these be installed? Will concrete coated pipe and a small RX be utilized or will it just be a "typical" pipeline spread digging up the watercourse?

Page 1-23.

BLM states that severe route conditions will result in an aerial RX. Severe route conditions are defined by NTPC as "very steep approaches to the stream bed such as canyons or gorges."

BLM states that the pipeline will parallel HVAC powerlines for 332.4 miles. These should be checked quite closely since some HVAC lines are located in some rather sensitive environmental areas; side hills, river bottoms, as examples.

Page 1-24. Mainline Valves.

BLM states that block and check valves will be installed to isolate pipeline sections in case of oil leakage from the line; on either side of PS, and at waterway crossings, as required by DOT. As per DOT requirements mainline valves will be installed at each of the following locations:

a) each side of PS.
b) lines to and from tank farms.
c) "on the mainline at locations along the pipeline system that will minimize damage from accidental discharge of crude oil, as appropriate for the terrain in open country or for locations near cities or other populations."
d) on each lateral line, ?
e) "on each side of a water crossing that is more than 100 feet from high-water mark to high-water mark."
f) "on each side of a reservoir holding water for human consumption."

BLM in Table 1.4-12, pages 1-25 and 1-26, lists the location of mainline valves as proposed by the NTPC. There is no analysis of the maximum spill volume for all pipeline sections. What is the maximum probable oil spill that could occur at sensitive areas, river crossings, and the like? BLM states that all PS and the pipeline RGV's will be remote controlled from the OCC. What type of leak or spill detection system will NTPC have? What about seismic or earthquake considerations as relates to design and oil spill probability analysis?

34 CONT

⑪

Pages 1-24 to 1-32. Pump Stations.

PS are shown as having no buildings over the pumps, manifolds, and the like. How will this function in cold weather as relates to an oil spill induced shut off? On the TAPS pump stations, all the pumps, turbines, manifolds, and controls are located in heated buildings.

All NTPC's PS do not appear to be permanently staffed. Who will respond to an oil spill? How will these people be trained and equipped? Also, NTPC's communications system should be designed to insure a timely response in case of an oil spill or other system malfunction.

Due to the noise of the pumps and maintenance activity, all PS should be located away from sensitive wildlife areas. This includes siting away from watercourses since PS are prone to leaks and human errors that generate oil spills. Reference: TAPS PS #8 Explosion, and TAPS PS #9 Major Oil Spill.

NTPC plans to have "yard lights" around all PS. These lights will effect wildlife use of the adjacent areas during nighttime. NTPC will have back-up diesel fueled generators at each PS. How will the generator fuel be stored and handled? NTPC states that they will need permanent all weather access roads to each PS. Some of these APS will no doubt be new roads. This impact must be considered during the PS site selection and review process.

All pumps at NTPC's proposed PS are run by electric motors and therefore HVAC lines must be built to each PS. The HVAC lines will vary from 69 to 230 KV. These HVAC lines pose additional environmental considerations and they should be considered as part of the PS for PS siting purposes. NTPC states that their proposed PS will have a demand of 121.3 megawatts of electrical power at initial pipeline capacity and 349.6 megawatts at ultimate pipeline throughput. NTPC states that initial demand within Montana is for 39.0 MW with a final demand of 92.8 MW. Questions: Where is this power supposed to come from? Does NTPC presently have power contracts?

Pages 1-32 to 1-37. Delivery Facilities.

NTPC plans delivery facilities at its PS and intersection with the Glacier pipeline where NTPC plans to build 847,000 barrels of crude oil storage. At NTPC's intersection with the Western Crude Oil Line, 394,000 barrels of crude oil storage are slated for construction. Due to possible ruptures of storage tanks, associated noise and traffic, and other permanent disturbances, it is best to locate these proposed delivery facilities away from sensitive wildlife resources and all watercourses.

Page 1-35 and Figure 1.4-10 on page 1-38. Stages of Construction.
Page 1-41. Pipeline Construction.

NTPC intends to construct all the pipeline portion in just 8 to 12 months, mostly from April to November. This time limit to build over 1,500 miles of large diameter pipe in conjunction with NTPC's stated manpower and equipment estimates is, in my opinion, totally unrealistic if adequate environmental safeguards are enforced by the governmental regulatory agencies.

NTPC's inspection plan - QC/QA is not conducive to independent or meaningful quality control. For example, NTPC plans to have only two inspectors per pipeline spread or section. This number appears low especially when one considers all the paperwork requirements NTPC has outlined for their inspectors. Who will be watching the construction? NTPC should be required to have an independent QC/QA program. The QC/QA personnel must have stop work authority to be effective. NTPC's QC/QA plan should be specifically reviewed and approved by all government permitting agencies before any field construction is allowed to commence.

On the TAPS, the pipeline company, APSC, had undue influence over the inspection activities and procedures of their QC subcontractor -- Bechtel, Inc. And as a result, effective QC was almost totally lacking on the TAPS. For instance, due to falsification of records, no records, and a host of other reasons, APSC was forced by the Federal Government to re-x-ray over 4,000 welds that did not have proper documentation. These approximately 4,000 welds were on already buried below ground pipe or on already installed above ground pipe. These re-x-ray activities would have been unnecessary if there had been proper QC inspection and documentation, and therefore, due to this lack of an independent adequate QC/QA program, APSC caused unnecessary environmental problems during their re-x-ray program. It has been estimated that this re-x-ray due to inadequate QC, cost APSC (and finally all oil consumers - us) over $80,000,000.00.

Furthermore, to insure that NTPC's QC/QA program actually functions according to approved procedures, there must be continuous government surveillance and monitoring of all NTPC's work during a) preconstruction and planning, b) construction, c) O&M, and d) termination. The government inspectors must also have stop work authority. On the TAPS, the cost of all government surveillance, State and Federal, was fully reimbursed by APSC. This condition should also be applied to the NTPC as a mitigating measure. Continuous government surveillance is necessary to insure that the conditions of the various governmental permits are followed by NTPC and all their contractors/subcontractors. Continuous government surveillance will also enable on-site evaluations by government personnel to make additional restrictions or delete unnecessary permit requirements as the site specific conditions change or warrant. This minimizes environmental problems and actually speeds pipeline construction.

One additional note: NTPC should have environmental QC inspectors with stop work authority to enforce governmental mandated environmental stipulations. Reference the Environmental Stipulations attached by the U.S. Congress to the Grant and Agreement of ROW for TAPS.

Page 1-41. Pipeline Construction.

NTPC is requesting a permanent ROW of 75 feet plus an additional 15 feet of temporary ROW for a total disturbed width of 90 feet. This is very wide. APSC has a TAPS permanent ROW of 54 feet and the actual construction ROW was in most cases limited to that amount. NTPC states in their DPA but not in their BLM EIS, that "Narrower widths will slow construction process, increase costs, and aggravate the potential for accidents." NTPC should be requested to prove this claim and to submit data to substantiate their need for the requested ROW width.

CONT

⑪

How will the ROW be cleared? By Hydoax? By hand clearing? The latter should be done within 100 feet of all water bodies. What will be done with the debris? How much of a civil effort will be needed? How much WP will have to be built on unstable soils? How many MS will be needed? Where will these be located? The picture on page 1-42 shows a cat simply pushing over trees and tearing up the soil. This was not allowed on the TAPS and should not be permitted if NTPC is allowed to build their proposed pipeline.

Figure 1.4-11 on page 1-43 is entitled, "TYPICAL PIPELINE CONSTRUCTION SPREAD" in large capital letters while below in fine print it is stated "not drawn to scale". This figure depicts most of the standard pipeline construction procedures from clearing to final cleanup on one page. This presents the viewer with the entirely false impression that construction activity will be limited to a very short segment of pipeline ROW at any one specific time. This is entirely false. A typical pipeline construction spread is often simultaneously working on a 10-20 mile or greater section of ROW (see BLM's estimate of 8-16 miles for 2 weeks to 1 month on page 3-56). This BLM figure should be omitted because it is deceptive. If this figure is retained, the "not to scale" should be in large capital letters like the figure's title, plus it should also state, in large capital letters, that a "typical pipeline construction spread" often occupies 10-20 miles of ROW. Pipeline construction is not as nice and neat as this BLM figure (quoted from the NTPC) would have one believe.

Page 1-44.

BLM states that all the pipe will be coated, but BLM does not say what coating will be applied. This is a very important consideration because some pipeline coatings work better than others and this in turn affects the long term oil spill frequency rate due to corrosion of that pipeline.

Figure 1.4-12 on page 1-45.

NTPC's drawing shows padding under the pipe (according to specifications). What are these specifications and where will the padding come from? What are the locations of the needed MS? The extraction of gravel from flood plain or in-river material sites caused very serious short and long term environmental problems on the TAPS. (Reference JFWAT Special Report Number 13 on MS site selection and operations.)

Under the column titled "Crossing of Water Courses", NTPC states that the width of the ditch at the bottom of RX is 76 to 78 inches" with implied near vertical ditches walls. From TAPS experience, this is incorrect since ditch wall slough or erosion by flowing water, plus the natural angle of repose of the sub-stream bed material caused RX ditches to widen greatly at the top and bottom. On the TAPS RX at the Chena River where that river was only 300 feet wide, the excavated ditch approached 100 to 150 feet wide at the top before the ditch was excavated deep enough for proper (below depth of project design scour) pipeline burial. (Reference JFWAT Section III Surveillance Reports.)

Figure 1.4-13 on page 1-45.

DOT regulations require that all pipelines be buried at least 48 inches below the river beds. On page 1-18, BLM indicates that the Northern Tier Pipeline would be buried below the depth of scour at all river crossings. Often the depth of scour is greater than the 48 inch minimum cover requirement. How deep the pipeline would be buried below the rivers will determine in part how much material must be excavated to obtain the necessary ditch depth which in turn affects the amount of silt that buried RX's will generate. The more digging in the riverbed, the more siltation, and the greater the impact on downstream aquatic resources. However, the pipeline must be buried below the maximum scour depth so that the pipeline would not be exposed and subjected to rupture during flood conditions.

Page 1-44 and 1.46.

BLM states "RX will be constructed in accordance with the requirements of the permitting agencies and sound engineering practice." Underlining is the reviewer's. What does this mean? Would NTPC directional drill all RX's if so required by the various government permitting agencies? BLM indicates that during RX excavation NTPC's backhoes, draglines, or the like will operate in the water. This should not be allowed due to fuel, grease, and hydraulic leaks that would directly enter the water. NTPC wants instream storage of excavated material at RX's. This should not be allowed, as it restricts the stream flow channel and causes additional siltation. The USACE does not allow the instream storage of excavated material. If necessary, you can use a suction dredge and pipeline to move the excavated material to shore storage. Where physically possible, NTPC should be required to flume or by-pass pump all small streams while they are installing their pipeline under those waterways. BLM states that NTPC plans to dewater, with well points, sand bottom streams carrying subsurface water to permit a dry excavation during pipeline crossing.

1) How will this effect downstream aquatic resources that are dependent on this subsurface flow?
2) What will be done with the water?

BLM indicates that stream bottoms of solid rock will require blasting. The shock waves that are generated by blasting will kill fish and other aquatic organisms. Underwater drilling and blasting was not done on the TAPS. I suggest a bored or aerial RX at these sites. With the number of major and minor RX's NTPC has to do in Montana, and with the equipment and manpower figures NTPC has presented, I seriously doubt that NTPC can clear the ROW at RX's, weld pipe, x-ray, coat, concrete coat, hydrotest, excavate, pull pipe, backfill, and do restoration with the time limits (8 to 12 months total; 1 to 3 months use at each RX) that NTPC has presented. This is especially true when one considers that all stream crossings work will most assuredly have to be performed within Montana Fish and Game Department approved critical timing windows and at low stream flows to make the physical aspects of construction easier. From TAPS experience, you need a detailed site specific RX plan for each RX plus a site specific RX restoration plan.

Page 1-46.

How does NTPC propose to install their pipeline in flood plain situation? Excavation in most flood plains will result in a ditch full of water due to groundwater flow into the excavated area even if the surface watercourse is not entered. On the TAPS, this type of construction caused major environmental problems because APSC wanted to dewater the ditch before lowering in the pipe. The silty water was pumped from the ditch and in a flood plain situation, it was difficult, if not impossible, to keep this silty water out of the adjacent watercourses which often resulted in the siltation of sensitive fish streams.

CONT

⑪

Page 1-47. Hydrostatic Testing.

This section does not tell you how the hydrotest would be done. There is no mention of 1) water sources, 2) length of test segments, 3) discharge points, etc., etc., etc. A detailed hydrotest plan is needed. Hydrotest water should not be discharged into waterways because 1) there is oil and grease inside the pipe (and in the discharge water--reference TAPS Data on the Salcha River hydrotest) from the internal mandril of the pipe bending machine, 2) rust, 3) dirt, etc. You also must have an energy dissapation system controlling the discharged hydrotest water to prevent all erosion. Water removal for hydrotest uptake may be critical during low stream flows especially when on considers irrigation withdrawals. On the TAPS, APSC was not permitted to withdraw more than one-fourth of the actual stream flow. How will NTPC's water withdrawals for hydrotest mesh with Montana water laws and water ownership rights? Especially low flows that are left in the watercourses to maintain the fisheries resources?

APSC did not move hydrotest water from section to section for any great distance. It was fill/dewater, fill/dewater over and over again. In the TAPS Section III hydrotest for 156 miles of pipeline, there were five water sources and approximately ten discharge points. APSC wanted several more water intake sources, but APSC's request was denied due to insufficient stream flows or because instream excavation would have been needed on the smaller streams for placement of the hydrotest pump intakes. APSC wanted the water to be a minimum of six feet deep at all withdrawal points for their withdrawal pumps to properly function. NTPC states that they will "cleanup" their hydrotest water before discharging that water into watercourses. How does NTPC propose to "cleanup" this water?

Page 1-47. Restoration.

These should be government approved restoration revegetation specifications. The reclamation specifications should also apply to all private land unless the landowner specifically objects; as was done on the TAPS. NTPC needs to institute erosion control measures during construction. These procedures should be planned before any construction begins. On the TAPS, APSC had a system of "greensheets" for each homogenous portion of the pipeline system. APSC had hundreds of site specific erosion control and/or restoration greensheets or plans. These plans were necessary for government review and approval and because QC personnel need a plan to QC to. Everything must be in writing for verbal agreements are subject to misunderstanding. Reference TAPS Stipulations, APSC Erosion Control Manual, APSC greensheets and APSC QC Manual.

In NTPC's "Preliminary Construction Schedule", figure 1.4-10 on page 1-38 under the heading Pipeline System, all pipeline construction is to be done between April 1, 1980 and December 1, 1980 with "system testing" scheduled for April 1, 1981 to July 1, 1981. Does this mean that the hydrotesting will be delayed until 1981? If so, NTPC will not want to do any restoration or vegetation until after hydrotesting since they must traffic the ROW during hydrotesting. This could result in serious erosional problems, as well as pose access problems across rivers and creeks. In addition, if hydrotesting is done in the early spring when the ground is still frozen, NTPC would probably have to add antifreeze, methanol or heat to the hydrotest intake water to keep that water from freezing inside their pipeline. Antifreeze or methanol would effect the water quality and prevent that water from being discharged without treatment to remove the methanol or antifreeze. Heating the intake water could cause thermal pollution effects when that water is discharged.

Pages 1-48 to 1-50. Operations and Maintenance.

BLM does not specifically discuss NTPC's leak detection system. What is the minimum detectable leak? That is to say, at what rate can the pipeline leak oil into Montana's environment without this being noticed by NTPC's remote leak detection system? DOT requires an aerial pipeline surveillance flight every two weeks. NTPC then states, "Areas where leaks may have developed can also be spotted by the line flyer . . .". This leaves some doubt as to the reliability of the NTPC's leak detection system.

How is the NTPC man on the ground who finds a crude oil leak going to be able to contact the necessary people immediately? On the TAPS, APSC has a communication system with their own relay towers where any APSC employee with a mobile unit can talk to anyone else on the 789 miles of the TAPS. APSC's mobile system also connects with the telephone system. That is to say, a man in the field can, via his mobile radio, direct dial any phone number in Alaska. A communication system is extremely important in generating the quickest possible response to an oil spill. This in turn allows for containment of the oil in the shortest possible time thus minimizing the environmental damage of that particular oil spillage.

Table 1.4.23, Page 1-51; Table 1.4-24, page 1-52; and Table 1.4-26, page 1-53 all present estimates of construction costs. The last cost item in each of these tables is very misleading. It is listed as "Environmental Studies, Engineering, and Construction Management", thereby implying that the majority of that line item cost is for Environmental Studies. This is not true. Most of the total for this line item will not be spent on Environmental Studies but on Construction Management or Engineering. This line item should read, "Construction Management, Engineering and Environmental Studies."

Page 1.54.

The tariff rate from Port Angeles, Washington to Minneapolis, Minnesota is listed as $0.184. How can this be when the tariff rate to Clearbrook, Minnesota would be $1.014 plus the tariff on the Minnesota Pipeline $0.170 = $1.184 not $0.184.

Pages 1-54 to 1-56. Oil Spill Contingency Plan.

APSC submitted a detailed 15 volume mainline oil spill contingency plan to APO and SPCO about 180 days prior to scheduled pipeline start-up. APSC's plan was then reviewed by all the government monitoring agencies and recommendations or corrections to APSC's plan were made. In some instances, APSC's preliminary oil spill contingency plan showed their oil flowing uphill from hypothetical pipeline breaks. Mainline oil spill contingency plans must be site specific, adequately detailed, and should contain many technical requirements, such as predesignated containment and booming sites on watercourses.

CONT

⑪

After APSC's mainline oil spill contingency plan was tentatively approved by APO and SPCO, the government ordered APSC to demonstrate their capability and readiness to execute their plans. The government's test involved simulated oil spills. The government notified APSC that the government would simulate a mainline oil spill within a segment of the pipeline during a certain week. APSC was not informed of the exact location or time of the government's test. For the actual test, the government called up APSC and told them that they had a break in their line somewhere in a 200 to 300 mile section. APSC then initiated their oil spill plan sending out helicopters, aircraft, and ground reconnaissance units. Government officials had marked the location of the simulated oil spill in the field by using black plastic on land and a green non-toxic dye in affected waterbodies. The government monitored and recorded APSC's detection time, response time, adequacy of simulated containment, and the like. In this manner, the government field tested APSC's oil contingency plan and APSC's implementation of that plan.

It is the policy of the U.S. Government that there should be no discharge of oil upon land or water during the life of the TAPS. This included construction. At the direction of APO and SPCO, Alyeska published a Construction Oil Spill Contingency Plan. APSC's government approved plan contained the names, addresses, and phone numbers of APSC personnel who were responsible for construction oil spill containment and cleanup. APSC's plan also listed the types of oil spill cleanup equipment that were kept in various pipeline construction camps and pump stations. APSC's plan also described basic oil spill containment methods and techniques.

During construction of the TAPS, APSC spilled large volumes of oil upon Alaska's environment. Estimates of the volume of petroleum spilled vary from 535,058 gallons to over 2,000,000 gallons, but the exact figure will never be known because of the nature of some of the spills, inadequate reporting and other problems.

In this regard, it should also be remembered that four major oil spills occurred in the first month of operations of the TAPS; a pipeline that was supposedly designed, engineered and built not to leak once in its 30 year projected lifeline. During startup, APSC experienced a human error coupled with a design failure as the crude oil reached pump station #8 that caused an explosion which completely destroyed the pump building and cost the life of one person. At pump station #9, a different design failure - human error problem resulted in the shutdown of that pump station when crude oil flooded the pump building and flowed out the door. On the north slope, a front-end loader operator backfilling around check valve #7, struck a 2-inch bypass pipe on that check valve and approximately 50,000 barrels of crude oil escaped to cover the tundra. One month later, crude oil was discovered in Washington Creek north of Fairbanks. Upon investigation, APSC discovered that the bolts on check valve #64 had never been properly tightened and that 50 to 150 barrels of oil per day had leaked out of the TAPS undetected for 30 days until that oil was discovered in Washington Creek.

Pages 1-56 to 1-58. Additional Measures Proposed for Environmental Protection.

The NTPC presented BLM with a list of 34 mitigating measures that it would institute. BLM lists these 34 measures and then presents a short one or two sentence discussion on the anticipated effectiveness of these mitigation methods.

1. Not applicable to Montana - NA.
2. NA.
3. Paint all storage tanks and landscape PS.
4. One Environmental QC per section. This is not enough; at least 2 or 3 are needed. Environmental QC must have stop work power.
5. Restoration - NTPC states that "yes, we will restore the ROW". This is not specific enough, lacks detail. Where is the enforcement power?
6. NA.
7. NA.
8. NTPC proposes to survey their pipeline route anywhere from a few months to several days prior to construction (DPA). Here NTPC states that they will retain archaeologists to evaluate the previously undisturbed portions of the ROW for things of archaeological significance after surveying that ROW but before construction. This does not appear to allow much time for the archaeologists to do their work.
9. NTPC proposes to reroute or reschedule pipeline construction if #8 identifies an archaeological site that cannot be recovered in time to permit pipeline construction. This would be effective only if adequate time is allotted in #8 above.
10. Landscape all mainline valves.
11. Water dusty ROW during construction in urban areas.
12. Use blasting mats to limit blast throw. I believe that this is an OSHA regulation.
13. Provide settling ponds as needed to reduce siltation of streams.
14. NA.
15. NA.
16. NA.
17. NTPC will route pipeline to produce the minimum number of RX's. This is sound engineering practice.
18. NTPC will route pipeline to avoid recoverable coal resources.
19. NTPC will route pipeline to avoid Little Missouri River and Missouri National Grassland.
20. NTPC will route pipeline to avoid crossing the Yellowstone River.
21. NTPC will compute depth of scour at each RX prior to construction. This is sound engineering practice.
22. NTPC will avoid rivertraining structures and rip-rap. These cost money and hence it makes economic sense to avoid them if possible.
23. NTPC will follow all DOT codes and regulations. NTPC has to do this, by law.
24. NTPC will reroute the pipeline to avoid ecologically sensitive areas. Who will determine what is an avoidable ecologically sensitive area? Biologists from regulatory agencies should provide this information.

34 CONT

⑪ 25. "NTPC will provide advice and assistance to county and local governments to identify government programs (e.g., the Energy Impact Program) or other means under which grants, loans, or other income sources are available to energy impacted communities, and will assist, where necessary, in the application for these grants and loans. Anticipated effectiveness: The fiscal impact of the construction and operation of the NTPC facilities on local governments will be partially or totally mitigated by this means, at the time during which the fiscal impacts are experienced." NTPC's social impact mitigation measure is of minimal value and BLM's anticipated effectiveness is incorrect. NTPC would help local governments seek money from the State or Federal governments to pay for the social impacts caused by the NTPC. What if the State or Federal Government has no money? (Remember California Proposition 13.) How would this then mitigate the adverse social costs of the Northern Tier Pipeline?

26. "After the completion of the environmental impacts assessment process and permitting of the project, and prior to construction, NTPC will coordinate with the appropriate state officials or local planning agencies in each locality, to establish the availability of local labor and the potential for immigration of construction workers and their families and to establish the availability of housing for these persons. NTPC will arrange for development of a temporary housing plan and for the provision of temporary housing, preferably by local private persons or concerns, to meet the needs of the construction work force and their families. Anticipated effectiveness: To ensure ordered and planned housing of construction workers and their families and to minimize disruption of ongoing housing patterns in each locality." In their DPA but not in BLM's EIS NTPC states, "Construction and supervisory personnel will generally be housed in existing local facilities. Travel trailers may be used by some contractor's personnel for housing, but existing trailer parks will be utilized for accomodating these units." Questions: Where are these to be found in the rural areas NTPC intends to cross, especially in eastern Montana? People "just camped along the road" will generate a wide range of environmental problems such as sanitation, sewage, garbage which attracts animals and could increase the rabies problem, disturbance to wildlife, poaching, off road vehicle use, and much more.

27. NA.
28. NA.

Six measures duplicate other portions of the NTPC application and these were not discussed by BLM.

Page 1-58.
West Coast surplus is stated as 450,000 bpd; on BLM page 1-4, it is listed as 500-600,000 bpd for 1978 and 1,000,000 bpd by 1985.

Page 1-59.
Two competing proposals have been filed under the Public Utilities Regulatory Act of 1977; Kitamat and Foothills Pipeline. BLM needs to address this situation.

## Chapter 2. Description of the Environment.

Pages 2-1 through 2-47 on the marine terminal were not reviewed.

Page 2-47. Pipeline System.
This entire section is generally descriptive with few detailed facts.

⑫ On page 2-57, BLM states that scour depth for NTPC RX are based on NTPC field inspections in 1978. Table 2.1.2.6-6 on page 2-65, "Characteristics of Major River Crossings - Columbia Basin" lists NTPC scour depths of the major RX's in western Montana. How did NTPC arrive at its scour depth figures? What estimating techniques did NTPC employ? Are the scour figures the average scour depth or the estimated scour depth for the 50 year flood, hundred year flood, or what? This is extremely critical because the proposed pipeline must be buried at least 48 inches beneath the maximum flood scour depth or it would be exposed when that river floods.

Table 2.1.2.6-10 on page 2-71, "Characteristics of Major River Crossings - Missouri Basin" also lists scour depth measurements. The Big Dry Creek RX at pipeline mile 968 is listed as being zero feet wide, zero feet deep, zero velocity and having a scour depth of zero; but at the 100 year flood this crossing is estimated to be 250 wide. What this appears to mean is that when NTPC's consultants visited this RX on Dry Creek in 7/78 it was in fact dry with a scour depth of zero since there was no flowing water. If this is how NTPC estimated all their scour depth data, it is of little value in determining how deep the proposed pipeline should be buried at RX's (Also see comment on Figure 1.4-13 on page 1-45).

⑬ Table 2.1.2.6-6 lists only 12 major RX in the Columbia Basin but NTPC lists 20 major RX on pages 1-21 and 1-22. There is no discussion or information presented on the RX's on the Thompson River, two crossings of the Little Bitterroot River, North Fork Jocko River, and Middle Fork Jocko River. All these tables on RX's are misleading in that they give the casual reader the impression that there are fewer major RX's than there would in fact be if NTPC is permitted to undertake the project. These BLM tables should be revised to include all the major RX's.

Pages 2-78 to 2-88. Biological Components of the Aquatic System is extremely weak with practically no detailed information on Montana's rivers and streams. This is especially true of Table 2.1.2.6-17 "Fish Occurrence and Fishery Value in Selected Streams Within Major Drainages" as few rivers are covered and almost no meaningful data is presented.

Section 2.1.2.8. Terrestrial Vegetation.
BLM has provided a general discussion of the vegetation types crossed by NTPC proposed pipeline.

⑭ Section 2.1.2.9. Terrestrial Wildlife.
In a very general discussion, this section only addresses "Endangered Species" and "Areas of Special Concern". Other wildlife resources are not mentioned. On page 2-101, Bitterroot River should be changed to Little Bitterroot River (see comment on page 1-18).

CONT

Section 2.1.2.10. Cultural Resources.
General discussion of archaeological and historical resources.

Section 2.1.2.11. Visual Resources.
General discussion.

Section 2.1.2.12. Land Use.
General discussion. It is impossible to make specific comments and/or review when very few specifics are presented by BLM for consideration.

Section 2.1.2.13. Transmission and Utility Networks.

Section 2.1.2.14. Recreation Resources.

Section 2.1.2.15. Social and Economic Conditions.

Section 2.2.2. Future Environment - Pipeline.

## Chapter 3. Environmental Impacts of the Proposal.

Pages 3-1 to 3-55 on the marine terminal were not reviewed.

Page 3-57. Table 3.2.2-2.
BLM's fugitive dust estimate of 7700-11000 lb./day/per 5 mile working section may be conservative depending on soil type, precipitation, and the like. Dust will effect vegetation and in turn that vegetation's use by livestock or wildlife, as well as adding to particulate pollution of the air.

On page 3-59 BLM states, "Excavating and grading for the pipeline could block or divert small surface drainages and result in minor impacts of short duration, 5 years or less." The only way a drainage block or diversion would be of short duration would be if it eroded out in BLM's given five years. This degradation of the environment is unnecessary. Adequate drainage structures should be installed, and the ROW should be cleared and graded in a manner that would not alter surface drainage patterns. Reference TAPS Stipulations and TAPS experience.

⑮ On page 3-59, BLM states, "This impact would be most severe along the major streams, including the Columbia, Missouri, and Musselshell Rivers, because of their high streamflows." The Musselshell River is listed by BLM on Table 2.1.2.6-10 as having a maximum recorded flow of 16,000 cfs with an average discharge of 268 cfs. BLM's Table 2.1.2.6-7 lists the Clark Fork River as having a maximum discharge of 134,000 cfs with an average flow of 20,140 cfs. The Northern Tier Pipeline would cross several rivers "larger" than the Musselshell. BLM is not consistent in their presentation of this data.

On page 3-65, BLM states, "Revegetation of unpaved areas would be complete or well underway by the growing season following construction." Permanent erosion control measures should be implemented immediately after the pipe is buried to minimize environmental damage. The entire ROW should be stabilized by the winter of the construction season to minimize damage during the following spring breakup. Disturbed areas can be dormant seeded, as APSC did on some portions of the TAPS.

On page 3-65, BLM states, "Terrestrial oil spills and pipeline leaks would contaminate soils, reduce their productive potential, and increase their susceptibility to erosion. Pipeline spills would occur at an estimated frequency of 0.0022 spills per mile per year (OTW 1978). This is based on spills greater than 2.4 barrels (100 gallons). In terms of total length of pipeline, about 68.5 spills would occur in 20 years. A leak too small to be detected by remote sensing equipment could amount to as much as 3,540 barrels per day, assuming a throughput of 709,000 barrels per day. Soil contamination from this type of leak would continue until it was detected visually and stopped."

This means that if NTPC is permitted to build their pipeline, 3,540 barrels per day or 148,960 gallons per day could leak out of their pipeline on Montana's environment forever undetected by NTPC's remote sensing equipment. A leak of this size would go unnoticed by NTPC until a private citizen discovered the oil flowing over Montana's landscape or until that break was discovered by a NTPC line flyer. The line flyer would operate once every two weeks (page 1-49) so 3540 x 14 = 49,560 barrels or about 2,500,000 gallons could leak out undetected between line flights. If the leak was under 2-4 feet of snow, a common occurrence in Montana, it could leak all winter and the line flyer would never see it and NTPC would be unaware of the environmental damage until the spring's snow melt.

⑯ In addition, this 3540 bpd figure or 0.5 percent of the 709,000 bpd throughput, is not the current state of the art in pipeline leak detection technology. The TAPS automatic, remote sensing leak detection system was supposedly designed to detect a leak of 500 bpd at 2,000,000 bpd throughput or 0.03 percent. APO officials have indicated that the TAPS automatic leak detection system is, in actual practice, only able to detect a leak of about 1000-1200 bpd at 1,160,000 bpd average throughput or 0.09 percent to 0.10 percent. If NTPC is permitted to build their project, they should be required to install the best pipeline leak detection system that is presently available. The TAPS experience would be a good example.

⑰ On page 3-67, BLM states that they expect 2 to 6.5 cubic yards of sediment per foot of stream channel width to be washed downstream during excavation at waterway crossings. This figure needs to be compared with the sediment transport figures obtained for the TAPS Salcha River Crossing (reference Mr. Kim Francisco's JFWAT Special Report Number 17). At least 1,166 tons of suspended sediment were introduced to the Salcha River during the 17 days of pipeline installation. The Salcha River was approximately 300 feet wide during TAPS installation; 3.9 tons of sediment were generated per foot of pipeline crossing.

⑱ On page 3-67, BLM states that the hydrotest withdrawal rate would be 6 cfs or 2700 gallons per minute. This figure should be checked against the TAPS hydrotest withdrawal rate. BLM indicates that NTPC may want to add soda ash and/or a bacteracide to their hydrotest water to reduce internal pipe corrosion. This would effect hydrotest discharge water quality and is another reason why hydrotest water should not be discharged directly into watercourses. BLM states that they see no problem discharging hydrotest water directly into streams. As previously discussed (reference JFWAT Surveillance Reports and Analysis of Salcha River Hydrotest Water), there

CONT

⑱ is a problem of oil in the discharge water. This oil comes mostly from the hydraulic leaks associated with the internal mandril that is used in the pipe bending machine. BLM did not address this problem; BLM says none exists, which is an error.

⑲ Table 3.2.6-1 on pages 3-68 and 3-69. "Estimated Sediment Increase Construction."
How did BLM obtain their estimates of trench length, trench width, trench depth, trench volume, and sediment increase? Is trench depth calculated from the top of the water surface or the top of the river bottom? BLM's "stream velocity" column is given in cfs and as such should be titled stream discharge not stream velocity. The "data" that BLM has presented in this Table appears to be incorrect. The Clark Fork River "data" will be used as an example though the following comments are applicable to the entire Table. There are 5 proposed buried crossings of the Clark Fork River in Montana; at pipeline miles 533, 538, 539, 540, and 553. The Clark Fork flows from East to West and 533 is the downstream crossing. BLM lists the five Clark Fork River crossings as having discharges of 10,000 cfs, 5,000 cfs, 1,000 cfs, 1000 cfs, and 10,000 cfs. The 533 crossing downstream is listed as having a discharge of 10,000 cfs while the uppermost crossing at mile 553 is also listed as having a discharge of 10,000 cfs. The Thompson River and a few small streams enter the Clark Fork between mile 553 and 533, yet BLM claims that the discharge is identical. Unless there is a water loss from the system this is impossible. Above the Thompson River, the Clark Fork River breaks into three channels separated by islands. These are the 538, 539, and 540 RX's. BLM lists the discharge of these three channels as 5,000, 1,000, and 1,000 cfs for a total 7,000 cfs yet BLM lists the 533 and 553 RX crossing at 10,000 cfs. What happened to the 3,000 cfs difference in these figures. These discharges for the Clark Fork are also not similar to the discharge data BLM presented in Table 2.1.2.6-7. In this Table, BLM lists the five Clark Fork RX's as having lengths of 625, 600, 350, 500, and 600 feet respectively. However, Table 2.1.2.6-6 states that the Clark Fork River is 650, 850, 550, 675, and 675 feet wide at these five crossing sites. How does BLM propose to install the RX's when their trench lengths are less than the actual widths of the river? In normal pipeline RX construction the pipe RX trench is usually 100 feet or more longer than the width of the river at the RX.

How did the BLM "estimate" the trench volume—or the amount of river bed material that would have to be removed during RX construction?

OEA TABLE ON ESTIMATED RX TRENCH VOLUME

| Clark Fork Crossing | BLM Trench Length-Feet | BLM Trench Depth-feet | BLM Trench Width-feet | BLM Trench Volume Cubic Yards | Vertical Walls*** | Ditch Wall Slope 1:1 | 1:2 | 1:3 |
|---|---|---|---|---|---|---|---|---|
| | | | | | | in cubic yards | | |
| 533 | 625* | 25 | 6.5 | 8264 | 3761 | 16,348 | 30,016 | 43,547 |
| 538 | 600 | 20 | 6.5 | 5644 | 2883 | 10,331 | 18,222 | 28,111 |
| 539 | 350 | 15 | 6.5 | 2175 | 1264 | 3,549 | 6,465 | 9,382 |
| 540 | 500 | 13 | 6.5 | 2667 | 1565 | 3,912 | 7,042 | 10,171 |
| 553 | 600 | 22 | 6.5 | 6511 | 3178 | 12,344 | 23,100 | 33,855 |
| 533 | 650** | 25 | 6.5 | 8264 | 3912 | 17,002 | 32,047 | 45,289 |
| 538 | 850 | 20 | 6.5 | 5644 | 4092 | 14,639 | 27,231 | 39,824 |
| 539 | 550 | 15 | 6.5 | 2175 | 1986 | 5,576 | 10,159 | 14,743 |
| 540 | 675 | 13 | 6.5 | 2667 | 2112 | 5,291 | 9,506 | 13,731 |
| 553 | 675 | 22 | 6.5 | 6511 | 3575 | 13,887 | 25,988 | 38,088 |

*Data in this column is from BLM Table 2.1.2.6-7.
**Data in this column is from BLM Table 2.1.2.6-6.
***Calculated trench volume assuming vertical ditch walls, ditch walls at 1:1, 1:2, and 1:3 slope.

In the above OEA Table, it was assumed that the bottom of RX pipe trench was about 6.5 feet wide, a reasonable assumption that would leave only about 1.5 feet on each side of the 40" OD pipe when it would be placed in the RX pipe trench. If the natural angle of repose of the stream bed material would allow vertical ditch walls, only about one-half the BLM estimated trench volume would have to be evacuated from the river. But if the natural angle of repose of the stream bed material was 1:1, 1:2, or 1:3, the amount of stream bed material that would have to be excavated would be approximately twice, four times, and five times the BLM estimate.

⑳ BLM trench evacuation estimates do not account for the volume of material that would be washed into the excavated area by the flowing river which would also have to be removed to obtain the proper ditch depth. On the TAPS, the natural angle or repose of stream bed material excavated at RX's varied from 1:1 to 1:4. The Chena River at the TAPS crossing outside of Fairbanks is 300 feet wide. The excavated RX ditch was about 600 feet long due to the possible lateral migration of the Chena River during the TAPS' lifetime. The Chena pipe ditch was approximately 25 feet deep. Due to a natural angle of repose of the Chena River bed material that approached 1:4, the width of the pipe trench at its top was in excess of 150 feet while it was still only eight feet wide at the bottom. APSC had originally stated that it would take their Execution Contractor ten days working 24 hours a day to excavate the Chena RX. It took the Execution Contractor 27 days working 24 hours a day to actually excavate the Chena pipe ditch. The BLM does not appear to be realistic in their estimates of the amount of in-river excavation and river disturbance that would be associated with the proposed Northern Tier Pipeline river crossings.

㉑ How did BLM obtain the estimate of Sediment Increase (in ppm) during RX construction. On the five Clark Fork RX's, BLM estimates the sediment increases as 20 ppm, 110 ppm, 470 ppm, 540 ppm, and 50 ppm. At what distance below the RX did BLM make these projections? The 20 ppm and 50 ppm figures appear to be underestimated. The river bottom may be gravel, cobbles or sand, but below this natural armouring layer silts and clays are packed around the larger material.

The Salcha River at the TAPS crossing southeast of Fairbanks has a gravel, cobble bottom, King salmon used to spawn right at the crossing. During RX construction at the Salcha River, the Alaska Department of Fish and Game and the USGS collected water samples to try and determine the effects of the TAPS buried RX. This data was published in JFWAT Special Report #17. During RX construction of the Salcha River the actual measured suspended sediment values range from 1-8 ppm above the pipeline crossing, 10-648 ppm 450 feet below the RX, 15-504 ppm at 1,450 feet below, 40-115 ppm

CONT

at one mile, 25-115 ppm at 1½ miles, 14-79 ppm at three miles and 7-40 ppm at eight miles below the Salcha River TAPS crossing. The low suspended sediment values below the crossing correlate with construction inactivity, and the high values were associated with ditch excavation.

㉒ Table 3.2.6-2 on page 3-70, "Maximum Potential Oil Spill" is calculated on the length of pipeline below the rivers between valves. If you have a river crossing, then a valve, followed by a five mile long hill with no additional valves, and the pipeline broke just on the downflow side of that valve, five miles of pipeline would drain onto the riverbanks and most probably into the river. In this Table, BLM also lists "minimum detected spill" with ranges from 490 bpd to 6360 bpd with the average of the 48 listed RX being 1845 bpd. However, on page 3-65, BLM states that the minimum detectable spill would be 3540 bpd. These two BLM statements do not appear to be compatible.

㉓ On page 3-72, BLM states, "Sediment would slightly reduce the production of cold water fishes (salmon and trout)." "Sediment would cover spawning gravel and smother eggs incubating in the gravel for a short distance downstream from the crossing and smother eggs incubating in the gravel." "Most of the sediment would be washed out of the gravel during the first period of high flow consequently one year - class of fish (eggs of fish of the same age) would be most heavily impacted. Subsequent spawning runs of these populations would be reduced for several cycles but probably within the range of normal fluctuations. Consequently, the reductions would not be noticed. . ." "Some insect populations would also be lost in the impacted area and fish normally feeding there would be displaced to other areas of the stream." "Oil would clear rapidly from streams. . .". The underlining in the above BLM quotations is the author's. BLM does not provide any sources, references, or data on which BLM based their conclusions. In the author's opinion, the BLM statements are in error. For example, the sediment washed out of the gravel from below any RX then settles only further downstream where it effects additional aquatic resources. BLM's contention that "oil would clear rapidly from streams. . ." neglects the fact that oil contamination of the stream side soil and vegetation results in long term oil "leakage" into that aquatic system. Reference Prospect Creek, Galbraith Lake, and other major construction spills on the TAPS.

In an October 30th, 1978 letter from Mr. Robert H. Torheim, Regional Forester, Northern Region, Missoula, Montana, to Mr. Albert F. Lachard, Northern Tier Project Manager, BLM, Portland, Oregon, Mr. Torheim transmitted the official USFS review comments on BLM's preliminary Draft NTPC EIS. In his letter Mr. Torheim stated,

> "Cumulative or synergistic results of several individual impacts are not discussed. An example of this is the fisheries discussion. Individual impacts relating to turbidity, sediments, loss of food source, etc., are discussed and generally noted as being of minor magnitude and duration. However, all of these stresses placed on a fish population and its habitat at the same time may be very detrimental to existing and future populations.
>
> "Sediment production impacts are not limited to the stream crossings and immediate downstream areas. These sediments are going to be continually washed downstream for several years, eventually settling in such places as reservoirs."
>
> "In summary, we feel the environmental impact statement must contain the information necessary for the land managers and public to thoroughly understand the impacts and trade-offs associated with this major project."

It appears that BLM did not heed the advice of the USFS in the completion of the NTPC Draft EIS.

㉔ On page 3-72, BLM states that only low shrubs would be allowed to become reestablished on riverbanks. Why is this so? On the TAPS, APSC actually planted trees and shrubs at some of their river crossings. Why could APSC do this and NTPC not do it?

㉕ On page 3-72, BLM states, "Fish entering the pipe during water withdrawal (for hydrotest) would suffer 100 percent mortality. . .". This is unnecessary. All pump intakes should be surrounded by a three to four foot square, screen covered box. This pump screening technique was utilized on all the TAPS hydrotests. These large screened boxes prevent fish uptake and prevent fish from being sucked and held by pump suction against a small screened pump intake.

On pages 3-72 and 3-73, BLM states that construction oil spills would be of short duration and volumes would probably be limited to a few gallons or less. This is contrary to what was experienced during construction of the TAPS. APSC spilled between 500,000 and 1,000,000 gallons of petroleum products during construction. (Reference JFWAT Special Report #15.)

There are many ways to minimize fuel spills at RX's:
1) No equipment should be allowed to operate from in the water.
2) Equipment should be moved back 100 to 300 feet from the bank to be fueled or serviced.
3) Steam clean equipment before it works near water. If any equipment is ever allowed to be worked in water or to drive across streams, that equipment should be steam cleaned before it is allowed to get into the waterway. This was done on the TAPS.
4) Repair all hydraulic or oil leaks before that equipment gets near any stream.

㉖ On page 3-169, BLM states, "There would be no significant impact resulting from test water discharge." Underlining is the author's. Incorrect - see previous hydrotest comment on BLM page 1-47. Of course, this all depends on how "significant" is defined.

On page 3-75, BLM states, ". . .the loss of fish in a relatively short stream segment should not have a critical effect on the population." Reference previous USFS quotations on cumulative effects and long term sedimentation effects.

㉗ BLM does not discuss the adverse effects at small streams. In Alaska, these smaller streams are often more important to the entire fisheries resource than the main rivers. At certain times of the year these smaller streams are the spawning and rearing areas for the fish that later move back into the larger rivers. Just because a waterway lacks width is no reason to assume that small streams are not an important part of the fisheries ecosystem. On page 3-78, BLM states, "Sediment impacts to fish populations would be minor in

34
CONT

㉗ streams containing little or no spawning habitat such as the Columbia River and the lower portion of the Clark Fork River." If this is true, these fish must then be spawning in the small side streams.

On page 3-78, BLM states, "A leak detection system capable of sensing a .5 percent loss of throughput volume would allow a leak under this limit to go undetected by the remote sensing system. A leak of up to 3,540 barrels per day with a throughput of 709,000 barrels per day and up 4,660 barrels per day with a 932,000 barrels per day throughput could occur and would continue until detected visually and stopped." See previous comments on BLM pages 1-54 to 1-56 and 3-65.

On page 3-78, BLM appears to be implying that the pipeline would have to break under a stream for oil to get into that stream. This is not true. The pipeline could leak oil into a non-fish containing watercourse which could then flow into a more sensitive fisheries resource area.

㉘ Section 3.2.8. Terrestrial Vegetation.
On page 3-80, BLM states that no herbicides will be used by NTPC to maintain their pipeline ROW. However on page 3-84 BLM states, "The corridor would be maintained by mechanical removal of woody vegetation supplemented by limited chemical control at approximately 5-year intervals." Again, the underlining is the author's. What are the standard industry practices for maintenance of pipeline ROW? The Yellowstone Pipeline Company should be consulted since their ROW crosses Montana along a route similar to that proposed by NTPC. How are the various powerline ROW's maintained in Montana? On page 3-80 they say no herbicides will be used and on page 3-84 they say herbicides will be used at 5-year intervals. This is contradictory.

On page 3-84, under the heading of "Endangered and Threatened Species", BLM states, "Although several such species probably inhabit the project ROW, no unique habitats are known to be within the corridor, and no adverse impacts are expected." Underlining is the author's. The lack of discovery does not mean lack of impact.

Section 3.2.9. Terrestrial Wildlife.
This section is also very general.

On page 3-84, BLM states, "The magnitude of disturbance impacts depends largely on timing." This is a very true statement - critical timing or allowable construction windows are the prime mitigating technique to reduce the adverse impacts on wildlife once a pipeline centerline has been selected. Figure 3.2.9-1 gives periods of sensitivity to disturbance of susceptible species.

㉙ On page 3-86 to BLM's list of construction phase impacts to wildlife should be added: 7. Poaching by construction workers. APSC did not allow any firearms (aside from authorized security personnel) on the TAPS project.

㉚ Table 3.2.9-2. "Potential Impacts to Wildlife on Areas of Special Concern." This Table does not appear to be comprehensive. Where did BLM get their "impact values"? For example, BLM does not mention open B/G ditch effecting wildlife - deer, elk, antelope and the like.

㉛ On page 3-93, BLM states, "Approximately 80 bighorn sheep in the Clark Fork River area (pipeline mile 529) would be disturbed. Construction activities and human intrusion are likely to cause the loss of one year's production of young. Ewes displaced from spring range and receiving harrassment or unusual disturbance might not obtain adequate nutrition for successful lambing." BLM appears to be willing to "write-off" one year's bighorn lamb production if NTPC is permitted to build this project. A solution that the bighorn's would be much more agreeable to would be to require NTPC to build this portion of the pipeline when that area was not critical to the bighorn sheep.

Section 3.2.10. Cultural Resources.

Section 3.2.11. Visual Resources.

Section 3.2.12. Land Use.

Section 3.2.13. Transportation and Utility Networks.

㉜ On page 3-110, BLM engages in a general discussion of the HVAC lines that would have to be constructed if NTPC is permitted to build their planned pipeline. BLM states, "O&M power use would represent significant load increases for a number of serving utilities." Where would the power needed by NTPC come from?

Also, on page 3-110, BLM discusses the relationship between HVAC and pipeline induced currents. This is an extremely important consideration in designing a cathodic protection system.

Section 3.2.14. Recreational Resources.

㉝ On page 3-115, BLM lists, "increased opportunity for access into remote or unwooded areas" as a positive advantage of the Northern Tier Pipeline. Many people would classify this as a negative impact for this would reduce that area's wilderness quality.

Section 3.2.15. Social and Economic Conditions.

㉞ Page 3-121. Housing.
BLM states, "A current study will address moving-site construction projects. Results will be presented later." On page 3-119, BLM states that 47 percent of the work force would be out-of-state people in construction sections 3-7. In Table 3.2.15-6 BLM lists 16-19 percent of the work force as being "local" within Montana.

On page 3-125, BLM states, "Impacts of antagonisms between community residents and pipeline workers would not be significant. Preliminary findings on past pipeline projects indicate that these workers have been generally well received by communities. Leisure time activities are similar and therefore not disruptive to community members and workers have tended to maintain an adequate social distance (Mr. West, personal communication, 1978)." This is contrary to Alaska's experience during construction of the TAPS.

CONT

Chapter 4. Mitigating Measures Not Included in the Proposed Action.

㉟ On page 4-1, BLM states, "Impact reducing measures proposed by the Northern Tier Pipeline Company (NTPC) but not included in the description of the proposed action and measures that government agencies explicitly stated they will enforce are termed 'committed mitigating measures.' Impacts that would remain after all 'committed mitigating measures' were applied are termed 'unavoidable impacts'. They are summarized in Chapter 5." "Presently available information on the proposal describes the pipeline route in terms of a 2-mile-wide corridor. The port and onshore storage facilities are described in terms of initial design specifications. This information is not sufficiently detailed to identify and quantify most site specific impacts. Federal, state and local agencies generally require more specific information on proposed locations, design of system components, construction, and reclamation methods, and operating procedures to determine what mitigating measures would be required under existing regulations and codes. Similarly, private landowners need more site specific details about the proposal in order to determine what measures they would require as easement provisions." Then why has BLM issued a Draft EIS?

The recommendations in this Chapter are general and are a good start, but there are many other mitigating measures that can be added. In addition, those BLM listed need to be expanded and detailed: reference TAPS, JFWAT, and APO documents plus previous comments. BLM provides a general discussion of critical timing at RX's, all fish streams, and wildlife areas. Reference JFWAT fish stream list for the type of data needed prior to any construction.

NTPC has proposed to locate the pipeline and related facilities to avoid vulnerable wildlife habitats. Avoidance of ecologically sensitive areas and habitat of threatened and endangered species could mitigate most of the impacts to wildlife resulting from habitat alteration and disturbance. The effectiveness of this measure depends on:

1) the criteria used to define sensitive areas. . .
2) who determines "vulnerable wildlife habitats" - NTPC? or the Montana Department of Fish and Game? This is one of the prime reasons why biologists must have input and veto power in the early pipeline routing and design.
3) Actual avoidance of those areas.

On page 4-6, BLM states, "Mitigation efforts will be two-fold including 1) planning procedures and 2) on-the-ground site specific analysis of development activities." The author agrees with this BLM statement; a continuous government surveillance effort will be needed for meaningful environmental protection if NTPC is permitted to build their planned pipeline system. BLM also states, "Planning stipulations will partially mitigate impacts by directing the appropriate agencies to require development activities 1) during less seasonally critical times to wildlife and 2) under minimum time schedules." An example of the latter would be to require NTPC to work 24 hours a day at RX's once an instream activity has commenced to minimize the time that the river is physically disturbed. Furthermore, BLM states, "On the ground mitigation will require the presence of a wildlife biologist during construction, operation, and abandonment activities. Mitigating measures could include 1) avoidance of impacts to previously unidentified nests, staging areas, and 2) coordination with construction supervisors to moderate disturbance to wildlife and wildlife habitat." This appears to indicate that BLM is proposing that there be continuous government surveillance with stop working authority if NTPC is permitted to build. The underlining in the above quotation is again the author's to stress a most important point, trained experienced biologists should make the biological decisions, not engineers and the biologists' work to be meaningful must have veto power over engineering decisions of mere convenience or money.

The Trans Alaska Pipeline System was constructed under provisions of the Agreement and Grant of Right-of-Way for Trans-Alaska Pipeline entered into on the 23rd day of January, 1974 by the United States of America and seven owner companies that operated through the Alyeska Pipeline Service Company (APSC). General legal, management, organization and engineering requirements were set forth in the body of the Agreement and Grant. More specific requirements were detailed in five exhibits that were attached to the Agreement and Grant.

The State of Alaska entered into a right-of-way lease for the Trans-Alaska Pipeline with the Alyeska Pipeline Service Company that was modeled after the Federal Agreement and Grant. The State and Federal Stipulations were nearly identical and constituted an integral part of the respective U.S. Government and State of Alaska lease and grant for pipeline construction. These stipulations were part of the "Trans-Alaska Pipeline Authorization Act" (Public Law 93015)) passed by Congress and these stipulations were later translated into provisions of the Federal and State Grant/Lease. Congress incorporated these stipulations into law at the request of various political groups as a measure designed to mitigate the adverse effects of pipeline construction. Within these stipulations, were requirements for continuous government surveillance of the pipeline system with all government expenses reimbursed by the permittee/lessee, APSC. Congress decided that this condition was necessary to insure APSC's compliance with the conditions of their "Grant of Right-of Way". Continuous government monitoring and surveillance was the primary method utilized to mitigate the environmental disturbances associated with the construction of the TAPS.

The Federal Government through its Department of Interior Alaska Pipeline Office (APO), the State Pipeline Coordinators Office (SPCO) and the Joint Fish and Wildlife Advisory Team (JFWAT) monitored all phases of TAPS construction for four years. The TAPS involved the construction of a large diameter pipeline similar to the proposed Northern Tier Pipeline. There is a vast array of reports, documents and knowledge that is presently available on the TAPS experience. Why has the BLM not even mentioned the TAPS environmental stipulations that were attached by the U.S. Congress to the Alaskan Pipeline Authorization Bill? Many mitigating measures that Congress attached to their TAPS bill in 1974 aren't even listed, discussed, or evaluated by BLM. Why?

Chapter 5. Any Adverse Impacts Which Cannot Be Avoided Should The Proposal Be Implemented.

Pages 5-1 to 5-12 on the marine facility were not reviewed.

CONT

Page 5-15.
All the "unavoidable" adverse effects of open trench B/G RX's could be avoided by directional drilling all RX's. The use of flumes during B/G construction would also reduce the adverse impacts on smaller streams. On the TAPS, ¼ of the actual stream flow was used as the maximum allowable hydrotest water withdrawal rate as a means of limiting adverse effects due to water removal from the streams. The "unavoidable" adverse effects of an O&M line oil spill could best be mitigated by:

1) An adequate independent QC/QA during construction to insure that the pipeline is built according to all engineering specifications.
2) Prompt detection of oil spills; adequate leak detection system.
3) A detailed workable oil spill contingency plan with trained cleanup personnel and proper equipment.

On page 5-15, BLM states, "The pipeline must be buried 48 inches below 100 year flood scour depth to comply with DOT regulations." See previous comments on BLM page 3-67, Table 3.2.6-1, page 2-57, and Table 2.1.2.6-6.

Page 5-19.
Some ways to minimize, reduce, or eliminate adverse effects to wildlife:

1) Vegetation - leave undisturbed natural buffer zones along rivers, critical habitats and the like.
2) Construction activity restriction zones - critical timing.

Under Section 5.2.15, Social and Economic Conditions, some of the unavoidable impacts may be avoidable. BLM should review the Preliminary State of Alaska Social and Economic Stipulations for the soon to be built Alaska Northwest Gasline. BLM should also refer to the TAPS experience. APSC was required to build construction camps for all their workers. NTPC could be required to build construction camps along portions of the pipeline route that do not have adequate facilities.

Chapter 6. The Relationship Between Local Short Term Uses and the Maintenance and Enhancement of Long Term Production.

BLM states that none of these short-term uses are likely to have significant impacts on long-term maintenance or productivity of the resources. Not much new data is presented in this section.

Chapter 7. Irreversible and Irretrievable Commitment of Resources.

Very little is said in this Chapter and vitually no information is presented.

Chapter 8. Alternatives to the Proposed Action.

Section 8.1.1. No Action Alternative.

Section 8.3.2. Delayed Action Alternative.
These two alternatives are not favored by BLM because a) "must move surplus Alaska oil," b) "economic benefits", c) "national energy independence." See previous comments on BLM pages 1-3 and 1-4.

Section 8.4.1. Northern Tier Ports and Onshore Facilities Alternatives.
This section was not reviewed.

Section 8.4.2. Northern Tier Route Segment Alternatives.

Section 8.4.2.8. Nine Mile Creek - Helena.
This is the NTPC proposed route alternative to avoid the Flathead Indian Reservation. This route calls for 13 RX's of the Clark Fork and Little Blackfoot Rivers. Along Siegel Creek this route would go between Rare II areas 1-795 and 7-796, which are separated only by a road. These two study areas are recommended for wilderness classification only under the "all wilderness" alternative and are recommended for non-wilderness management under the other nine alternatives. However, the USFS could not issue a permit to NTPC until the Rare II study is completed.

Section 8.4.2.9. Nine Mile Creek - Helmville.

Section 8.4.2.10. Harlowton - Beach - Clearbrook.
This is a more southerly route proposed by NTPC with 15 major and 300 minor stream crossings.

In Table 8.4.2.11-1, BLM presents a comparison of environmental impacts on the route alternatives but BLM makes no recommendations as to the least environmentally damaging route.

Section 8.4.3. Port-Pipeline Alternatives.

Section 8.4.3.1. Alaska to Edmonton, Alberta (Foothills).
There are four proposals by Foothills:

1) Delta Junction,Alaska to Edmonton, Alberta, 500,000 bpd; 1,505 of new 30" OD pipeline to be built down the Alcan Corridor.
1a) Delta Junction to Key River, Alberta; 1,136 miles of new 30" pipeline.
2) Skagway, Alaska to Edmonton. The crude oil would move via tanker from Valdez to Skagway and Haines, Alaska where off loading facilities and storage tanks would have to be constructed. Then by 1,091 miles of new pipeline up and over White Pass, along Yukon Highway 6 to Jakes Corner, then down the Alcan Highway to Edmonton.
2a) Skagway-Key River, Alberta. This alternative is the same as 2 above but with the new pipeline ending in Key River, Alberta instead of Edmonton.

All four of these alternatives would connect with existing pipelines for transport of the crude oil to the U.S.

Section 8.4.3.2. Kitamat to Clearbrook, Minnesota.
Seven hundred fifty three miles of new 30 to 36 inch pipeline would be built from Kitamat, B.C. to Edmonton, Alberta. This plan would require a new tanker terminal to be built at Kitamat. This pipeline would go through Mt. Robson Provincial Park in British Columbia and Jasper National Park in Alberta.

CONT

Section 8.4.3.3. Transmountain Pipeline Reversal.
Seven hundred eighteen miles of 24 inch existing pipeline from Edmonton, Alberta to Vancouver, B.C. would be reversed to flow from Vancouver to Edmonton with an additional new 74 mile pipeline connection to the Puget Sound Area. From Edmonton the crude oil would be shipped to the U.S. via existing pipelines.

Section 8.4.3.4. Long Beach, California to Midland, Texas and Midwest (SOHIO).
SOHIO proposes to reverse and convert 790 miles of existing 26 and 30 inch natural gas pipeline to a crude oil pipeline and to build new pipelines of the following dimensions: 34 miles of 30 inch; 174 miles of 42 inch; 9 miles of 48 inch.

Section 8.4.3.4. Trans-Mexico Pipeline.

Section 8.4.3.6. Trans-Guatemala Pipeline.

Section 8.4.3.7. Transport by Tanker and Mid-Continent Pipelines.

a) Shipment around Cape Horn to Gulf Coast.
b) Shipment through the Panama Canal to U.S. Gulf of Mexico Coast.
c) Mid-Continent Pipeline System.

Section 8.4.3.8. Panamanian Transhipment (Northville).

Section 8.8.3.9. Summary of Port-Pipeline Systems.

Chapter 9. Consultation and Coordination.

Glossary and References.
There is not one reference to the TAPS or any document, publication, or report that originated from the TAPS experience. How can BLM write a draft EIS on a large pipeline project like the Northern Tier without making any reference to the one pipeline project that was continuously monitored by various governmental agencies during all aspects of its construction?

Map Addendum. 187 pages. Published as a seperate volume.
Alignment sheets 9-18 cover the State of Montana. There are two sets of Alignment Sheet Maps. One set delineates natural resources and impacts and the other denotes human resources and impacts. The maps are portions of USGS maps and have a scale of 1:250,000. The Northern Tier Pipeline is represented by a line approximately 1/16th of an inch wide. The pipeline therefore covers a strip about 1,302 feet wide when the NTPC has requested a 90 feet wide ROW. These maps are of a general informative nature but are of little value in determining specific locations and resources that would be impacted. It is one thing to draw a centerline on a topographical map and from that line make recommendations to minimize pipeline impacts, but quite another realization to actually see where the pipeline is scheduled to be built. Often a minor realigment of the pipeline to avoid a sensitive environmental area will be much less costly than the restoration of that disturbed habitat. In one instance on the TAPS, the shifting of that pipeline 500 feet to the east over a 21,000 foot section would have completely avoided a productive fish stream. Instead, APSC made four crossings and three channelizations of that stream which became known as Million Dollar Creek for the money that APSC spent restoring an area they could have totally avoided by a minor change in the pipeline alignment.

㊱ On page 154, under "Impacts", item 3 should be changed from Flathead Indian Reservoir to Flathead Indian Reservation.

㊲ Summary. 82 pages. Published as a separate volume.
Most of the above comments are applicable to the BLM summary statement and will not be repeated here.

The material printed on page 37 should be printed on page 36 and the material printed on page 36 should be printed on page 37.

On page 59, BLM lists the tariff rate per barrel of oil transported on the proposed Northern Tier Pipeline as $1.30 in the initial phase and $1.11 in the ultimate phase from Port Angeles to Clearbrook, Minnesota then via the Lakehead Pipeline to Chicago, Illinois (see previous comment on page 1054). On page 61, BLM states that the tariff rate on the proposed SOHIO pipeline would be $1.53 from Valdez, Alaska to Midland, Texas. These tariff rates are not comparable because BLM did not include the tanker shipping charges from Valdez, Alaska to Port Angeles, Washington in its estimate of the Northern Tier tariff. BLM also did not include the cost of moving the SOHIO transported oil from Midland, Texas to Chicago. Why did BLM not list comparable tariff rates for these two competing pipeline proposals?

Portland, Orego
97208

Sir,

①

I'd like to present an alternative Idea to Carry the Alaskan Crude to Central U.S.

Why not buy the Milwaukee Road and transport the oil on it. i other Words put the pipe line on wheels.

This would stop all the Seattle give away or rather keep a lot more jobs that seem to be doomed.

As this Idea spreads I think you will find that more people will be going railroad with it.

Of Course it depends on the market whether enough oil could be transported this way.

Also what are you going to do with a pipe line when the oil runs out.

The railroad will still be there as it has been for some 50 yrs. and still usable for other freight. I still think that a R.R. is the most economical as it can be maintained cheaper than most Road beds.

Yours truly
Dan J Foran

PSCOG
Puget Sound Council of Governments

March 8, 1979

Mr. Murl Storms
Oregon State Director
Bureau of Land Management
Post Office Box 2965
Portland OR 97208

Dear Mr. Storms:

The King Subregional Council, acting through the Committee on Growth and Development has reviewed the Draft Environmental Impact Statement for the Crude Oil Transport System as proposed by the Northern Tier Pipeline Company. The normal method of reviewing a DEIS is to compare the proposed action with the adopted Goals and Policies for Regional Development, and the King Subregional Plan. However, neither document speaks directly to projects of the magnitude of the proposed action. Therefore, the King Subregional Council wishes to take this opportunity to comment on the impacts without assessing the overall nature of the proposal.

1. The Bureau of Land Management and the Northern Tier Pipeline Company are encouraged to maintain close and continued contact with local jurisdictions throughout the duration of the project.

2. The proposed route and potential alternate routes pass through environmentally sensitive areas as noted in the DEIS. Where physically possible, environmentally sensitive areas should be avoided; at a minimum, impact mitigation measures should be reviewed with local governments. Specifically, water course disturbances should be minimized and timed to minimize impact on the fisheries resource.

3. Permanent disruption of agricultural lands should be avoided through alignment decisions and construction techniques. The natural soil horizons should be maintained.

4. The pipe line right-of-way provides an opportunity to allow public access to river and open spaces for boating, recreational purposes, a trail system, and green belts.

Mr. Murl Storms
Page two
March 8, 1979

Care should be taken to consider those possibilities in a coordinated fashion which balances agricultural use, public access and open space or right-of-way development for optimal benefit.

5. Where possible, a single right-of-way should be utilized for multiple transmission or transport facilities.

① 6. The project should be analyzed for its potential affect on population and employment in the King County area. Will the right-of-way influence the location or pattern of development? Will construction employment impact housing and public service provision in rural King County? Will construction employment on the pipeline affect the availability of construction workers for housing development thus adversely affecting housing cost?

It is the hope of the King Subregional Council and the Committee on Growth and Development that the comments and questions in our review will be useful to you and to other officials in reaching decisions on this very significant proposal.

Respectfully,

Mayor Gary A. Zimmerman (Bellevue), Chairman
King Subregional Council

cc: Nick Lewis, Executive Secretary
Energy Facility Site Evaluation Council

Portland, OR 97208

Dear Sir/Madam:

In response to the Draft Environmental Statement on the crude oil transportation system from Port Angeles, Washington to Clearbrook, Minnesota as proposed by the Northern Tier Pipeline; I suggest that the Environmental Statement be modified in its final version to include the following recommendations:

① 1) Placement of a block valve on the west side and check valve on the east side of the Big Coulee (Mauvais Coulee) crossing at approximate pipeline mile 1373.

2) Placement of a block valve on the west side and check valve on the east side of the Channel A crossing at approximate pipeline mile 1385.

3) Prompt implementation and maintenance of Best Management Practices along the pipeline route, as identified in the North Dakota Statewide 208 Water Quality Management Plan, (Non-point source).

4) Timing construction to occur after July to minimize sediment transport from disturbed areas in Big Coulee and Channel A.

5) Consultation with the Devils Lake Basin Advisory Committee prior to withdrawal and release of hydrostatic test water.

6) A pipeline wall thickness of 0.625 inches be utilized at the Big Coulee and Channel A crossings.

If you have any questions, please feel free to contact me.

Sincerely,

Michael Sauer

NORTHERN TIER PIPELINE
Written testimony
Connie N. Townsend
White Sulphur Springs, MT
March 9, 1979

I would like to take this opportunity to voice my support for the Northern Tier project. As ranchers we are more than aware of the far reaching implications of an oil shortage. With the construction of the Northern Tier pipeline, Montana refineries would have the assurance of a dependable supply of oil. All agriculture, a major economic base for the state of Montana (as well as our own livlihood), would benefit from the Northern Tier project.

In addition to the much needed oil supply, the added revenue to the states in taxes and employment during the actual construction should be of prime consideration.

That Northern Tier has been in the planning process since 1975 attests to the groundwork done by this consortium in preparation for the actual construction phase. The time has long since passed when we can afford to bypass or view such a development with apathy. Knowing full well in advance that we can no longer rely on Canadian oil, it would seem pertinent that new transportation facilities be constructed immediately for the abundant Alaskan supply. In addition....as regards the Canadian oil supplies, were we better able to supply our own oil within our own boundaries, the old adage would never ring more true: "a little oil saves much friction"!

Since Northern Tier would connect with existing pipelines in Montana, North Dakota and at Clearbrook, Minn., the refineries in the north and central areas could once again operate at capacity.

The fact that there has been no serious environmental objections raised by the BLM of the Department of the Interior should help assure environmentalists that Northern Tier will have little adverse effect in the crossing of the states involved. Northern Tier's close cooperation with the Bureau of Land Management demonstrates the sincerity of their effort to adhere to strict environmental standards.

In closing I would recall the words of Bacon: "There are three things which make a nation great and prosperous—a fertile soil, busy workshops and easy conveyance for men and commodities." Needless to say, the Northern Tier project will provide busy workshops and a much needed, easy conveyance for that most necessary commodity OIL which when refined will aid in easy conveyance for man. Can we afford to do less for the future of our children and our country?

Calvin M. Entinger
2025 W. Sussex
Missoula, Mt.
59801

Bureau of Land Management
Oregon State Director
Northern Tier Project
Room 1250, Lloyd Building
700 N. E. Multnomah
Portland, Oregon 97232

Dear Sirs:

I am writing you in regard to your "Draft Environmental Statement" on the Northern Tier Pipeline. I find your statement lacking in the following areas.

① A. All estimates given of projected shortfalls of crude oil in the states to be served by Northern Tier were made by the applicants themselves. Surely the conflict of interest is easy to see here. Independent studies must be done to determine if there is an actual need for the pipeline.

② B. The section of the statement that deals with alternatives to the pipeline fails to fully consider the many viable alternatives to the pipeline. Nowhere do I find an analysis of what effect a massive conservation program might do to eliminate the "hypothetical shortfalls. The statement simply assumes that our need for oil is going to keep on increasing. In addition competing projects that might meet these shortfalls are dismissed with but brief comment.

③ C. I find that the statement mentions the tax benefits to accrue to those areas the pipeline passes through but nowhere do I find an estimate of the dollar loss communities will have because of the pipeline. Admittedly it is diffeclut to place a dollar value on such things as visual impact, streambed disruption, oil spills, contamination of groundwater, and reduction of wildlife habitat, but such an estimate must be made if we are to know the true "cost" of the pipeline.

In summary, your statement has focused much too narrowly on routing alternatives and preconcieved assumptions of shortages rather than reviewing this project in terms of an overall energy program. If this had been done and had proper weight been accorded to conservation measures I think your statement would have found the Northern Tier proposal not only "uneconomic", but also, grossly wastefull of our environmental resources.

sincerely,

Calvin M. Entinger

George Wuerthner
Box 7192
Missoula, Montana 59807

March 10,1979

BLM Northern Tier Pipeline Coordinator
BLM Western District Office
Portland, Oregon

Dear Pipeline Coordinator,

I am opposed to the construction of the Northern Tier Pipeline. I don't feel that an adequent need for this massive construction project has been presented. Other alternatives have not been fully investigated. I suggest that oil get to the mid west by having pipelines connect with existing pipelines in Canada, for instance using the pipelines that extend from Vancounver,B.C. to Edmonton, Alberta. These then connected to the mid west.

Secondly, the Alaskan oil could be left in the ground. We don't have to keep the pipeline (Alaskan ) flowing at full capacity. We could bring enough oil from Alaska to meet existing market needs, but no more than can be refined on the west coast. It might be cheaper for west coast refineries to install the necessary equipment for refining high sulfur Alaskan oil than it is to build a new pipeline across the United States.

Finally, I don't believe that the benefits to Montana are worth the losses. I have seen what pipeline maddness did in Alaska and I can see what oil, coal and other developments are doing to Wyoming. In each case, the stable communities were disrupted. Influx of workers created social problems, increased the need for public services, created housing shortages and in general degraded the living environment. We don't need this in Montana.

Thanks,

Sincerely,

George Wuerthner

March 10,1979

BLM Pipeline Comment
BLM Western District Office
Portland, Oregon

Dear BLM Pipeline Organizer,

I have been following the controversy surrounding the Northern Tier Pipeline proposal that would cross Montana and several other northern states from Washington to the Mid west. I am opposed to this pipeline being constructed.

First, I don't believe there is a need for a new pipeline. There are several alternative such as connecting up with existing pipelines in Canada or having refineries in California install the proper equipment to process high sulfur Alaskan oil.

Second, we could always keep more Alaskan oil in the ground. Only ship enough to the west coast that can be used at any one time. The Alaskan Pipeline companies of course don't like this proposal because they don't make as much money, but they are the same companies that told the American public that there would be an oil shortage and consequently a market for Alaskan oil on the west coast. Now they ask us the American people to bail them out with an expensive pipeline that would cross many acres of fine agriculture, wildlife habitat and scenic land. I don't believe we should pay for their mistakes with the sacrifise of the western landscape.

Third, the impact of pipeline construction on our small towns and our local economies is something that we in Montana don't want or need.

I suggest that other alternatives be looked into. The Northern Tier route is not the best or most benefical to our nation's goals of energy conservation.

Thanks,

Sincerely,

Lori Hudak

Lori Hudak

Comments on the Northern Tier Pipeline Draft EIS

I will present a summary of the major concerns of the State natural resource agencies. First of all, I would like to compliment the BLM and the Northern Tier Pipeline Company on the completeness and high quality of the draft EIS. We find that the proposed route through Idaho to be the most satisfactory of all the alternatives offered. We do, however, have some reservations about the draft EIS.

① First, we feel that the draft EIS should have addressed and evaluated the south fork of the Coeur d'Alene route as an alternative.

② Secondly, we are concerned about the volume of water that will be required for the hydrostatic testing of the pipeline. We feel that Plummer Creek and Pritchard Creek may not provide adequate volumes of water for the purpose without adversely impacting these streams. We would like to see the south fork of the Coeur d'Alene and St. Joe considered as sources of water for hydrostatic testing. We would like to be assured that the testing screens out fish, because fish would surely be killed if they were put through the pipe.

③ Thirdly, we would like to be assured that the contingency plan for oil spills and other accidents be reviewed by the State. Along those same lines, we feel that the present spill detection program is inadequate as a spill of a volume of three to four thousand barrels per day could conceivabley occur and not be detected by line sensors. Alternative and more sensitive means of detection of spills need to be addressed.

④ It is difficult to discuss decommissioning of a pipeline when you don't even have one pipe in the ground, but we feel that the draft EIS should cover all aspects of the pipeline from A to Z and that the eventual decommissioning of the pipeline and the associated impacts were not adequately discussed in the document.

⑤ The draft EIS acknowledges several federal programs such as RARE II, the Clean Air Act and the Safe Drinking Water Act; but does not address local 208 Water Quality plans. We feel this is an oversight and should be addressed because of the noted high erosion hazard along some of the proposed pipeline route and because of the number of watersheds crossed.

⑥ We feel that there should be some control of the access to the corridor of the pipeline for both safety reasons such as vandalism and sabotage and from an environmental standpoint such as off-road vehicles and hunters.

⑦ Finally, the draft EIS did not adequately discuss the necessary commitment of State resources to monitor both the construction and operation of the pipeline for compliance with State laws.

---

Bureau of Land Management
Oregon State Director
Northern Tier Project
Room 1250 - Lloyd Building
700 N. E. Multnomah
Portland, Oregon 97232

March 12, 1979

Dear Sir:

This is in regard to public hearings on the Draft Environmental Statement covering the crude oil transportation system proposed by Northern Tier Pipeline Company.

The Montana Water Development Association has been on record publicly within the state supporting this project in numerous ways. We have supported the passage of Montana House Joint Resolution No. 12 covering approval of the project and will continue to work towards completion. It is our opinion that this is the most feasible and the most beneficial project to the Northern Tier states that are threatened by future shortages of crude oil. It is also our opinion that this will produce the least environmental impact on our state as well as producing the greatest amount of benefits.

We urge you to recommend approval of this project and press for its completion as soon as possible.

Sincerely,

Jerry D. Bryson

Oregon State office.

As I am unable to attend the Conference on Oil & Oil Ports, to be held in Port Angeles this week I am sending a 'brief' that I wrote for the hearings in B.C. on the subject & much of the material in the brief is relevant to the question now.

I am definitely opposed to large tankers in the Gulf, & I think that far greater precautions & restrictions should be mandatory.

I also oppose a larger tank "farm" at Port Angeles

Sincerely Eve Smith

I have heard recently that there is a Canadian invention for sopping up oil - Pellets of some kind, that are very absorbent. I am trying to find out more details

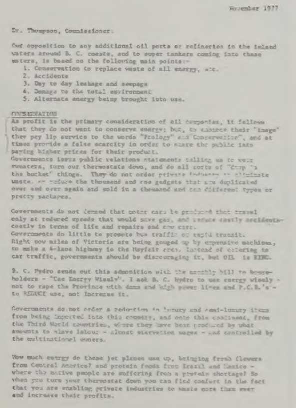
A SUBMISSION TO

THE WEST COAST OIL PORTS INQUIRY

by

EVE SMITH
South Pender Island
B. C.

November 1977.



November 1977

Dr. Thompson, Commissioner.

Our opposition to any additional oil ports or refineries in the inland waters around B. C. coasts, and to super tankers coming into these waters, is based on the following main points:-

1. Conservation to replace waste of all energy, etc.
2. Accidents
3. Day to day leakage and seepage
4. Damage to the total environment
5. Alternate energy being brought into use.

CONSERVATION

As profit is the primary consideration of oil companies, it follows that they do not want to conserve energy; but, to enhance their 'image' they pay lip service to the words "Ecology" and Conservation", and at times provide a false scarcity in order to scare the public into paying higher prices for their product.

Governments issue public relations statements telling us to wear sweaters, turn our thermostats down, and do all sorts of "drop in the bucket" things. They do not order private industry to eliminate waste, or reduce the thousand and one gadgets that are duplicated over and over again and sold in a thousand and one different types or pretty packages.

Governments do not demand that motor cars be produced that travel only at reduced speeds that would save gas, and reduce costly accidents-costly in terms of life and repairs and new cars.

Governments do little to promote bus traffic or rapid transit.

Right now miles of Victoria are being gouged up by expensive machines, to make a 4-lane highway in the Mayfair area. Instead of catering to car traffic, governments should be discouraging it, but OIL is KING.

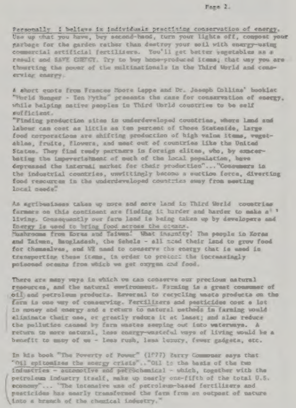
B. C. Hydro sends out this admonition with the monthly bill to householders - "Use Energy Wisely". I ask B. C. Hydro to use energy wisely - not to rape the Province with dams and high power lines and P.C.B.'s - to REDUCE use, not increase it.

Governments do not order a reduction in luxury and semi-luxury items from being imported into this country, and onto this continent, from the Third World countries, where they have been produced by what amounts to slave labour - almost starvation wages - and controlled by the multinational owners.

How much energy do these jet planes use up, bringing fresh flowers from Central America? and protein foods from Brazil and Mexico - where the native people are suffering from a protein shortage? So when you turn your thermostat down you can find comfort in the fact that you are enabling private industries to waste more than ever and increase their profits.

---

CONT



Page 2.

Personally I believe in individuals practising conservation of energy. Use up what you have, buy second-hand, turn your lights off, compost your garbage for the garden rather than destroy your soil with energy-using commercial artificial fertilisers. You'll get better vegetables as a result and SAVE ENERGY. Try to buy home-produced items; that way you are thwarting the power of the multinationals in the Third World and conserving energy.

A short quote from Frances Moore Lappe and Dr. Joseph Collins' booklet "World Hunger - Ten Myths" presents the case for conservation of energy, while helping native peoples in Third World countries to be self sufficient.

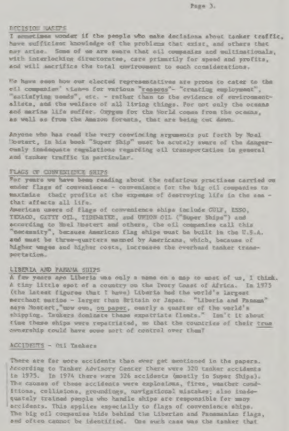
"Finding production sites in underdeveloped countries, where land and labour can cost as little as ten percent of those Stateside, large food corporations are shifting production of high value items, vegetables, fruits, flowers, and meat out of countries like the United States. They find ready partners in foreign elites, who, by exacerbating the impoverishment of much of the local population, have depressed the internal market for their production"..."Consumers in the industrial countries, unwittingly become a suction force, diverting food resources in the underdeveloped countries away from meeting local needs."

As agribusiness takes up more and more land in Third World countries farmers on this continent are finding it harder and harder to make a living. Consequently our farm land is being taken up by developers and Energy is used to bring food across the oceans.

Mushrooms from Korea and Taiwan! What insanity! The people in Korea and Taiwan, Bangladesh, the Sahels - all need their land to grow food for themselves, and WE need to conserve the energy that is used in transporting these items, in order to protect the increasingly poisoned oceans from which we get oxygen and food.

There are many ways in which we can conserve our precious natural resources, and the natural environment. Farming is a great consumer of oil and petroleum products. Reversal to recycling waste products on the farm is one way of conserving. Fertilizers and pesticides cost a lot in money and energy and a return to natural methods in farming would eliminate their use, or greatly reduce it at least; and also reduce the pollution caused by farm wastes seeping out into waterways. A return to more natural, less energy-wasteful ways of living would be a benefit to many of us - less rush, less luxury, fewer gadgets, etc.

In his book "The Poverty of Power" (1977) Barry Commoner says that "Oil epitomizes the energy crisis".."Oil is the basis of the two industries - automotive and petrochemical - which, together with the petroleum industry itself, make up nearly one-fifth of the total U.S. economy"... "The intensive use of petroleum-based fertilizers and pesticides has nearly transformed the farm from an outpost of nature into a branch of the chemical industry."



Page 3.

DECISION MAKERS

I sometimes wonder if the people who make decisions about tanker traffic, have sufficient knowledge of the problems that exist, and others that may arise. Some of us are aware that oil companies and multinationals, with interlocking directorates, care primarily for speed and profits, and will sacrifice the total environment to such considerations.

We have seen how our elected representatives are prone to cater to the oil companies' wishes for various "reasons"- "creating employment", "satisfying needs", etc. - rather than to the evidence of environmentalists, and the welfare of all living things. For not only the oceans and marine life suffer. Oxygen for the World comes from the oceans, as well as from the Amazon forests, that are being cut down.

Anyone who has read the very convincing arguments put forth by Noel Mostert, in his book "Super Ship" must be acutely aware of the dangerously inadequate regulations regarding oil transportation in general and tanker traffic in particular.

FLAGS OF CONVENIENCE SHIPS

For years we have been reading about the nefarious practises carried on under flags of convenience - convenience for the big oil companies to maximize their profits at the expense of destroying life in the sea - that affects all life.

American users of flags of convenience ships include GULF, ESSO, TEXACO, GETTY OIL, TIDEWATER, and UNION OIL ("Super Ships") and according to Noel Mostert and others, the oil companies call this "necessity", because American flag ships must be built in the U.S.A. and must be three-quarters manned by Americans, which, because of higher wages and higher costs, increases the overhead tanker transportation.

LIBERIA AND PANAMA SHIPS

A few years ago Liberia was only a name on a map to most of us, I think. A tiny little spot of a country on the Ivory Coast of Africa. In 1975 (the latest figures that I have) Liberia had the world's largest merchant marine - larger than Britain or Japan. "Liberia and Panama" says Mostert,"now own, on paper, nearly a quarter of the world's shipping. Tankers dominate these expatriate fleets." Isn't it about time these ships were repatriated, so that the countries of their true ownership could have some sort of control over them?

ACCIDENTS - Oil Tankers

There are far more accidents than ever get mentioned in the papers. According to Tanker Advisory Center there were 320 tanker accidents in 1975. In 1974 there were 326 accidents (mostly in Super Ships). The causes of these accidents were explosions, fires, weather conditions, collisions, groundings, navigational mistakes; also inadequately trained people who handle ships are responsible for many accidents. This applies especially to flags of convenience ships. The big oil companies hide behind the Liberian and Panamanian flags, and often cannot be identified. One such case was the tanker that

45
CONT

Page 4.

went down off the east coast of the U.S.A. and threatened the Georgia Banks fisheries.

STEVESTON
The crude oil spill August 30, 1977 brought the tragedy of spills closer to home once again. A team from Environment Canada was quoted in the Vancouver Sun, August 30 as saying, "They had not found any evidence of environmental damage yet, but it may be too early to tell."

Whenever there is an accident, be it oil or pesticides, or as gas or P.C.B.'s, etc., the governments and private industry play it down. -"no evidence yet"... Probably the microscopic marine life, the fish, etc. were aware of some "evidence of damage". The slick spread out over a large area so perhaps the "evidence" showed up later!

REGARDING ACCIDENTS - According to C.B.C. radio news for September 29, 1977 Dr. Andrew Thompson had made a public request to the Federal Government to make public the names of foreign ships that have caused pollution in Canadian waters. It seems that the Federal Government regarded such names of ships as "secret" or "confidential".

Canadians see their beaches being washed with oil; sea birds and other sea creatures suffering and dying, the microscopic food of sea life being polluted, and yet those who commit these depradations are to be protected - or is it the Government that is being protected - from us knowing that our elected representatives are allowing flags of convenience ships in these waters? Ships improperly manned? Ships inadequately provided with safety devices?

LETTER FROM THE OFFICE OF MINISTER OF TRANSPORT, October 11,1977 - According to this letter from Pierre Deniger, Special Assistant to the Minister of Transport, the U.N. Agency Intergovernmental Maritime Consultative Organization (IMCO) policies for pollution prevention "include additional navigational equipment and collision avoidance systems, improved methods of cleaning cargo tanks, the avoidance of the use of cargo tanks for the carriage of water ballast, and inspection routines to be carried out in ports to ensure compliance with the international standards previously mentioned." Surely, we could justifiably ask, "Why haven't all these measures been brought into use years ago?"

ARROW GROUNDED IN CHEDABUCTO BAY
The Arrow, owned by Onassis, one of the world's richest people, ran ashore at Chedabucto Bay and polluted with oil sixty miles of the Nova Scotia coast.

Most of us recall the Inquiry, headed by Dr. Patrick McTaggart Cowan, that exposed the fact that the Arrow's navigation equipment was not in serviceable condition. She sailed under a Liberian Flag. The radar was not working. The echo sounder had not worked for two months. The gyro compass was out three degrees - which is a lot. The ships third officer, on duty at the time of the accident, had no license. The Captain was the only member of the crew who had navigational ability.

Page 5.

The McTaggart-Cowan Inquiry issued this statement (in Part) ..."From the records available to us the standard of operation of the world's tanker fleets, particularly those under flags of convenience is so APPALLING AND SO FAR FROM THE KIND OF SAFETY WHICH SCIENCE, ENGINEERING AND TECHNOLOGY CAN BRING TO THOSE WHO CARE that the people of the world should DEMAND IMMEDIATE ACTION." Have we demanded immediate action?

My own letters to those members of Parliament responsible are answered in an unsatisfactory way. NOT ENOUGH IS BEING DONE by any of the responsible countries. They show a devastating lack of responsibility - as has been shown in reports coming from the Law of the Seas Conferences.

NEWEST EQUIPMENT - according to Noel Mostert, it makes little difference whether or not the Flag of Convenience Ships have the newest or oldest equipment because those in charge of these ships do not know how to use the equipment or how to repair it if it breaks down.

LEGAL CONTROLS - As has been obvious for some time there is no way of getting at the owners of ships of Liberia or Panama so their policies cannot be controlled and they cannot be called to account for negligence. Millions in profits continue to pour into the coffers of the oil companies and the world continues to be polluted and we the people continue to pay the price. And, according to a news item of September 27 and 28, 1977 we are paying the price of bribes as well. Exxon is reported as having spent millions of dollars in bribes. This really is not new news, its just that it is coming out into the open more now.

ACCIDENTS are causing havoc in many places - for instance they occur frequently off the coast of South Africa. A letter dated August 22, 1977 from South African National Foundation for the Conservation of Coastal Birds tells us that there were, at that time "two tankers on the rocks off Cape Town. Raging storms and high seas have caused increasing anxiety." "Pollution threatens our coastal birds." "Pollution is a truly international problem."

THE TORREY CANYON DISASTER

This accident off the south coast of England about ten years ago received an enormous amount of publicity and roused people's interest- but just how much has been done since then to prevent such devastating occurrences? If we don't move faster towards keeping the oceans clear, by the time fossil fuels have been used up, the oceans will be polluted beyond repair. So after ten years, with accident after accident causing serious damage, the office of the Minister of Transport tells me,"International Consideration, on a priority basis, is now being given to the problems of tankers..." BUT only now, after all these years!

For many years before the Torrey Canyon disaster, environmentalists, bird watchers and nature lovers were warning of oil damage to creatures in many places in the world.

CONT

Page 6.

Pierre Deniger's letter continues.."Where cases of flagrant disregard for the provisions of Canadian legislation are reported, action to prevent such ships entering Canadian waters can be taken, subject to authorization by senior officials of Transport Canada." How flagrant is "Flagrant"? And even if the act is found to be "flagrant", prevention is subject to decisions by Senior Officials. This gives plenty of room for all companies to commit crimes undeterred. There is also room for differences of opinion, with endless litigation, and "experts" can always be found who will favour Big Business.

Besides, we must bear in mind, that day to day seepage and leaks cause enormous damage by pollution. Not enough attention is given to eliminating these two hazards.

RISKS OF OIL TRANSPORTATION (Super Spill)

I quote an excerpt from a report made to the forty-third Legislature of Washington State in 1973 by the Oceanographic Institute of Washington re large tankers. "There is considerably more difficulty manoeuvring these large tankers. Their stopping distances can be measured in miles; and the quantity of crude oil that can be spilled is staggering - ( a grounding resulting in the rupture of one main or two wing tanks could release over four million gallons of oil from a modern 120,000 d.w.t. tanker)" - and 120,000 is not one of the larger sizes!

WEST COAST DEEP WATER FACILITIES STUDY - Washington State
"An oil spill in the approaches to the San Juan Islands could disperse throughout the archipelago with long term effects."....
"Impacts of a major oil spill ... would not necessarily be limited to the disruption of the natural environment, but could result in the severe economic damage to the fisheries, shellfish, recreation industries." ... "Prime importance must be given to the national and international responsibility of the local citizenry to preserve such a resource."

Being a local citizen, I take an international view of all these destructive, polluting problems. I look out on Haro Straits and see whales go by, seals on the rocks, gulls, ducks, terns and guillemots, an occasional otter or oyster catcher, crabs and other creatures that depend on the sea life for food. Now, for various reason, resulting mainly from human activity, many of these creatures are decreasing in numbers. Seagulls, as a result of human's filthy habits of garbage and sewage disposal, are on the increase. We should be grateful to seagulls because they help us to clean up our mess. We are responsible for their unnatural increase. I mention such things because oil is not the only pollutant that contaminates our frail ocean.

As Wesley Marx points out in his book "The Frail Ocean", estuaries are the nurseries of the sea. The B. C. coast has not got so many uncontaminated estuaries left. Wherever you go you see industries that pour harmful chemicals into water ways; or log booms, which, especially if they are cedar, tend to poison the water. The logging and mining industries pollute streams and rivers with their chemicals; and all rivers end up in the sea. Lead, mercury, zinc, cadmium, asbestos, fluorides, radio-active materials from nuclear plants, pesticides, herbicides,-all wind up in the sea.

Page 7.

In the 1950's after the bomb testing, Strontium 90 was found travelling in the waters of the Pacific Ocean. DDT was found thousands of miles from where it had been used. PCB's are more recent contaminants. Oil pollution cannot be considered as an isolated cause of pollution - only one of many - but oil is an especially great hazard in inland waters.

ALTERNATE ENERGY

One of the reasons that governments and industry give for not developing solar or other types of alternate energy is the cost. While millions are being spent on researching or developing solar energy, billions are spent on nuclear energy, oil exploration and cleaning up after oil spills - and all the money in the world does not bring back to life the creatures that die, nor does it compensate for suffering. And what of the money spent on the disposal of nuclear waste?

The Energy Research and Development Administration (U.S.A.) has estimated that it will cost Eighty Billion Dollars through the year 2005 to care for nuclear weapons waste alone. That does not take into account the lack of safety in waste disposal, nor the wastes from nuclear power plants. How many buildings could be heated, cooled, lighted, etc. with 80 billion dollars? How much research into solar or tidal or geothermal energy could be done with 80 billion dollars?

INDIVIDUAL ENTERPRISE

As is often the case, in experiments, individuals are building solar heated houses. More and more independent groups are researching and building solar heated houses, as has been done before.

The Fall 1977 issue of "CO-Evolution" published in Sausalito, Calif. carries an article on Solar Water Heaters in California in 1891 to 1930. It seems that solar heat was used in Florida, New England, Arizona and elsewhere. By 1941 there were 60,000 solar heaters in Florida. The war came and copper was frozen and gas and oil and electricity took ov

We oppose the Development of Nuclear Power on the grounds of danger, hazard to health, no safe method of waste disposal , and cost. The cost of dismantling obsolete plants is astronomical.
Windmills, methane gas, possibly tidal or geothermal power and certainly solar power, could at least augment the polluting and diminishing fossil fuels.

Minimum Use of Energy
In his book "Energy and Equity" Ivan Illich says "While people have begun to accept ecological limits on maximum per capita energy use as a condition for physical survival, they do not yet think about the use of minimum feasible power as the foundation of any of various social orders that would be both modern and desirable. Yet only a ceiling on enery use can lead to social relations that are characterised by high levels of equity....Participatory democracy postulates low energy technology."

CONT

Page 8.

We wonder if there is any use in making recommendations! Too much trust has been put in technological achievements, both prevention and in clean-up. Also, the technological achievements that are available have not been used to the fullest extent possible. Far from it.

We consider that conservation of energy is in its infancy - that governments are profligate in theif waste and in the weakness of controls on industry, especially in British Columbia - B. C. Hydro for example.

The money that is being put into nuclear power and oil development could better be used in developing alternate methods. We do not want to see any more of the devastation that dams cause.

Mexican Oil - N.Y. Times, Sept.25,1977 reports on Mexican plans to supply U.S.A. with gas and oil, from what is described as "vast reserves" so we believe that this could take the pressure off northern supplies. A report in International Herald Tribune (Paris,France) says that "Mexico's gas reserves are now privately believed to exceed 60 billion barrels, roughly six times greater than Alaska's north slope." (Alan Riding Feb. 18,1977). The Mexicans are (wisely in my opinion) debating whether or not this oil "should be exploited for short term economic advantage or be kept in the ground for future generations." A report from Mexico City (A.P.) February 22, 1977 says that the oil reserves are "much larger than the 60 billion barrel figure" according to the head of the state-owned petroleum company. If the U.S.A. can get gas and oil from Mexico, it would be an overland route which is a lesser evil than tanker traffic.

I see no reason why Canada should aid and abet the U.S.A. in its wasteful destructive habits - no sane reason that is. Conservationists in the U.S.A. have been promoting the Alternate Energy idea longer than we have - also reducing waste and in using energy more wisely. A few gains have been made but not nearly enough. When oil and fossil fuels are finished, and the Scientific, Business and Government Bureaucracies have finally admitted the hazards of nuclear energy, then they will turn to solar and other forms of relatively clean and renewable energy - and by then it may be too late.

I quote Frank Fraser Darling, a pioneer ecologist, from his book, "Wilderness and Plenty" - "Our task is to become symbiotic rather than parasitic on the earth's surface and if we can fulfil it we can save civilization from being an ultimate contradiction."

Eve Smith

BLM
Oregon State Director
Northern Tier Project
Room 1250, Lloyd Building
700 N. E. Multnomah
Portland, Oregon 97232

Dear,sir,

In view of the following facts, some of which taken directly from the Draft Environmental Statement, I find no alternative but to remain in strict opposition to the proposed project.

1) The Minnesota Energy Agency has denied a certificate of need which is essential before construction can begin.
2) The Confederated Salish and Kootenai Tribal Council has consistantly denied an easment for a pipeline right of way across reservation lands.
3) In 1976, Port Angeles voters passed a resolution opposing the project, ordinances and land use plans that could prevent construction of an oil transshipment facility have been approved by both city and county.
4) Damages from a major oil spill will cost millions in doller terms not to mention the irreparable harm inflicted on the land or sea.
5) The project as proposed is thus far lacking any environmental restrictions such as those applied during constrution of the Alaska oil pipeline. Consequently, the impacts of the NTP will be of greater magnitude than those in Alaska. This is totally unacceptable. WILL WE NEVER LEARN ?

page 2

6) The damage inflicted by the pipeline crossing the relativly unpolluted streams and fisheries is also unacceptable.
7) The proposal would require far more electricity than is presently available. This will facilitate accelerated demand for more powerplants and transmission lines.
8) Minnesota refineries will have to pay $3 per barrel charge vs. the 40¢ refineries are currently paying for the same oil shipped from the gulf. This is an elementary lesson in economics; Why pay $3 when you can pay 40¢ ?
9) Canadian crude oil cutbacks have been delayed untill 1985, why the rush to build Northern Tier ?

10) Northern Tier is one of 8 proposed shipment routes for Alaskan crude. All the proposals need detailed impact analysis before any are approved. It appears that the NTPC is being dealt with exclusively, which understandably arrouses suspicions as to corporate influnce in government agencys such as the BLM.
11) The major benefits of the pipeline are purely economic.

Hopefully environmental concerns play a more important role in the determination of the future of the proposal than do mere economic benefits. The quality of life in the land that we live in is far more important than dollars in the pockets of a few corporate executives.
As Bearhead Swaney so eloquently stated; "money is now; Land is forever. Its all we have left"

IN REPLY REFER TO: 150

MAR 13 1979

Memorandum

To: State Director, Bureau of Land Management
Portland, Oregon

From: ACTING Regional Director, Boise, Idaho

Subject: Draft Environmental Statement on Crude Oil Transportation System Proposed by Northern Tier Pipeline Co. (DES 79-3)

By memorandum dated February 13, 1979, to the Project Manager, Northern Tier Pipeline ES, BLM, we expressed our concerns about those aspects of the project affecting Bureau of Reclamation lands and operations in the Pacific Northwest and Upper Missouri Regions. Understandably, in preparing an environmental statement for a pipeline of this magnitude it is difficult to provide specifics and reflect other than general concerns. However, it remains that without more specific information we cannot with certainty identify the precise nature or the full range of impacts that will occur nor the number of Bureau projects and facilities which will be affected.

We do have some specific comments concerning the content of the draft statement for your consideration. They are as follow:

Alinement Sheets:

① There appears to be a gap in the map coverage between Alinement Sheets 12 and 13 along the shore of Canyon Ferry Reservoir.

② Sheet 13 should include a symbol showing significant terrestrial wildlife resources at the south end of Canyon Ferry Reservoir. The Montana Department of Fish and Game manages several thousand acres of Bureau lands for waterfowl upland game and big game between the community of Townsend and the Reservoir, and we are just completing subimpoundments to create 1,900 acres of marsh in this area. The corridor extends all the way between Townsend and the Reservoir and thus includes some of our area which would be quite subject to damage in the event of a spill.

Map Addendum:

③ P. 15 - The agency listings for the Bureau of Sport Fisheries and Wildlife and the Atomic Energy Commission should be replaced with current agency names.

④ P. B2 - Impacts on the Columbia River as a result of construction should be indicated as well as those from operations.

Draft ES, P. 1-59:

⑤ The statement, "The BR has study projects on the Missouri River and its major tributaries which could be affected by the proposal," should be replaced by a statement that Bureau lands might be crossed at Canyon Ferry Reservoir.

H.R. Stivers

cc: Commissioner, Attention 150

14 MARCH 1979

DEAR SIR,

I HAVE RECENTLY BECOME AWARE OF THE PROPOSED NORTHERN TIER PIPELINE AND THE MASSIVE IMPACT IT WILL HAVE.

I AM APPALLED AT THE LACK OF REGULATIONS AND RESTRICTIONS CONCERNING THE PIPELINE. IT IS OBVIOUS THAT minimal thought has so far prevailed.

I am informed that the pipeline in Alaska, even though girdled with suffocating government regulations and restrictions, witnessed countless blunders, mistakes and plain avoidance of many requirements. In fact, the Northern Tier developers are not even going to study the lessons that were learned in Alaska as they consider this project a completely 'independent' thing.

I ask if they were to build this giant varicose vein upon our (yours and mine) landscape would they even consider the impact? Having worked around contractors and engineers for many years, I am aware of one thing; they are generally lazy and take the path of least resistance. Their main concerns are speed and ~~being~~ getting the thing done & needless to mention, cashing their paychecks.

The Northern Tier contractors are in it for one thing – money. The oil company ~~for~~ profit. Who's concerned with the land, who will look after the wildlife, the trees, the rivers & streams? Sure they will put biologists to advise on the project, but what weight will their advice carry. What does some nature lover know the engineers don't, eh?

I believe that even if the strictest precautions were taken, if sound advisors were employed, if everyone had pride in the project and realized the magic of in accomplishing a feat ~~this~~ of this magnitude; that man, being human ~~as~~ he is, would cause more harm than good. That this project ~~was~~ like the others would take its toll.

It is not possible to construct this pipeline without vast sacrifices.

Let us look at the alternatives. Let us develop the alternatives.

I bitterly oppose this project along with thousands who must yield part of their 'backyard' to this selfish moneymaking.

Sincerely

[illegible] MONTANA.

Mr. Roger W. Burwell
District Manager, B.L.M.
Rm. 551, U.S. Court House
Spokane, WA 99201

RECEIVED
MAR 15 1979
Bureau Of Land Management
Spokane, Wa.

Dear Mr. Burwell,

① Enclosed article is part of the testimony to be submitted by Tahoma Audubon Society on the Northern Tier Pipeline Draft EIS. We request that the writers of the final E.I.S. try to find the studies quoted in this paper and to include the results (short paragraphs) in the final E.I.S. somewhere.

It is too easy to simply go ahead with plans even tho' there are serious questions remaining. The studies quoted in this paper show that there is good scientifically documented evidence of damage which occurs to marine systems when oil spills into the sea. We suggest a strong effort to look into this matter, taking full measure of the special characteristics of inland sea conditions as in Puget Sound and "river and dam" situations such as on the Columbia.

More later.

Sincerely,
Nancy Kiesning, Past President
Tahoma Audubon Society
3320 N Puget Sound Ave.
Tacoma, WA 98407

The article submitted with this letter was "Oil in the Sea: How Little We Know" by Frank Graham Jr., Audubon Magazine, November-December, 1978, pages 133-147.

**50**

Zane and Gloria Zell
816 1st Street South
Shelby, Montana 59474
#50

Dear BLM,

We carefully read over your summary of the Draft Environmental Statement for the Northern Tier Pipeline Project. We have a few comments and question we would like you to consider.

① During the construction phase you mention that permanent alteration of topography may result in certain mountainous segments of the route. Would you please specify where this would occur in Montana?

② You state that productivity levels of salmon spawning areas in streams in the pipeline corridor could be severely impacted and that these areas could take up to 20 years to recuperate. Could you specify to what degree would salmon productivity levels be affected? Is there a certain intolerable level which definitely takes priority over the existence of the pipeline? The potential for damage here seems to be sufficient to cancel the Northern Tier project.

③ The DES declares that thousands of acres of public forest land will be denuded by the pipeline corridor. Who will bear the social costs of this effect on our watersheds and wildlife habitat?

④ The pump stations will be a continuous source of noise and their demand for electrical power may exceed available supplies. This seems to defeat the whole purpose of placing them in rural areas. Hiding inefficiency and pollution is ~~the~~ not the answer to meeting our country's energy problems.

⑤ If the BLM and oil companies are sincerely interested in a dependable, efficient ~~crude~~ crude oil transportation system - one that would provide long range employment and economic benefits with minimal environmental impacts - they should consider the use of the "bankrupt" Milwaukee railroad line. If not by rail, the crude could be moved thru pipeline on the existing railroad right-of-way if Milwaukee decides to abandon the line. It was all public give-away land anyway.

We hope to hear from you soon. Sincerely,
Zane and Gloria Zell

Re: Northern Tier Pipeline

Dear Sir:

I have read the Draft Environmental Statement (DES) on the Crude Oil Transportation System as proposed by the Northern Tier Pipeline Company (NTPC) and have the following comments.

Since the DES assessed a route which is no longer under consideration my comments must necessarily be limited to broad and general issues rather than site specific.

① 1. It is my understanding that NTPC is to utilize existing rights-of-way whenever possible. The Montana legislature is also under the same impression as evidenced by House Joint Resolution 17 which states that "the Northern Tier Pipeline will be primarily along existing rights-of-way. . ." However, the DES indicates that over 460 miles of the 690 mile Montana segment will be new or unshared right-of-way (these figures may vary as the proposed route is in continuous state of change). The remaining segments are to be parallel to existing railroad, pipeline or transmission line corridors. Does parallel mean parallel to and within existing railroad, pipeline or transmission line rights-of-way or perhaps parallel to existing rights-of-way with a common boundary or parallel in the sense that it is also parallel to the equator? The Final Environmental Statement should clearly identify those areas where existing rights-of-way will be utilized and the amount of new right-of-way required.

51 CONT.

March 14, 1979
Northern Tier Pipeline
Page -2-

② 2. The amount of irrigated agricultural land to be disturbed in each alternative route should be calculated. If in fact, "operation of the pipeline across potentially irrigable land (does) serve as a significant deterrent to future irrigation and drainage plans" (p. 3-102) the impacts must be assessed in greater detail. Contrary to the statement on page 3-106, in my opinion, the pipeline facilities system would seriously constrain land-use planning and zoning.

③ 3. The proposed route as well as several alternative routes pass through areas containing extensive bentonite deposits. The ability and advisability of constructing a pipeline in material that is able to expand up to fifteen times its own size should be addressed in greater detail. The ability to accomplish surface restoration in these areas is highly questionable. To compound the situation, sufficient amounts of "rock free soil and sand" for use as "padding material" may be at a premium.

④ 4. Given the information presented, the indicated route between Thompson Falls and Missoula should be re-evaluated in the following areas:

Beginning near the center of Section 17, T21N, R28W, south of the town of Thompson Falls and the Clark Fork River and proceed in an easterly direction along the south side of the Clark Fork River passing through the following sections:

March 14, 1979
Northern Tier Pipeline
Page -3-

SW¼, Section 16, T21N, R29W
NE¼, Section 21, T21N, R29W
N½, Section 22, T21N, R29W
N½, Section 23, T21N, R29W
N½, Section 24, T21N, R29W
S½, Section 18, T21N, R28W
S½, Section 17, T21N, R28W

parallel existing pipeline
existing transmission corridor

S½S½, Section 16, T21N, R28W
N½, Section 22, T21N, R28W
SW¼, Section 23, T21N, R28W
NE¼, Section 26, T21N, R28W
S½, Section 25, T21N, R28W
SW¼SW¼, Section 30, T21N, R27W
NE¼, Section 31, T21N, R27W
N½, Section 32, T21N, R27W

This route would eliminate two crossings of the Clark Fork River and one crossing of the Thompson River.

5. Given the information presented, the I-90/94 corridor should be included and assessed as a viable alternative for the following reasons:

a. The I-90/94 corridor is already paid for. The costs of utilizing the I-90/94 corridor should be assessed and compared to the anticipated costs of acquiring new easement and rights-of-way.

March 14, 1979
Northern Tier Pipeline
Page -4-

b. The I-90 corridor will facilitate easy access for construction, surveillence, leak detection and repair, which in turn reduces costs to the consumer.

c. The environmental impacts and disruptions may be reduced and in some cases eliminated. There are some concerns regarding the number of river crossings involved with the I-90 corridor. However, is it absolutely necessary to bury the entire pipeline? Can rivers and large streams be spanned above the surface? Obviously, the state of the art exists as is evidenced by Aleyska's spanning the Yukon River in Alaska.

d. NTPC has indicated that they desire a working right-of-way of from 90-100 feet. The Trans-Alaska pipeline is a larger diameter pipe and yet was constructed in a 54 foot right-of-way. In most areas, it is felt that the I-90/94 right-of-way can provide a majority of the necessary work space without disrupting the flow of traffic. Short term construction disruptions and detours have been tolerated by Montanans for over a decade during the construction of the interstate highway system. We have no reason to believe this project would be substantially different.

e. The added assurance of immediate leak detection and ease of access for repair is obviously quite attractive.

March 14, 1979
Northern Tier Pipeline
Page -5-

⑤ 6. There are several issues surrounding the automatic leak detection system that need to be expanded and clarified. Page 6-3 of the DES states that "Minor pipeline leaks are expected to occur quite frequently throughout the life of the project." On what basis is that statement made and what exactly is a "minor pipeline leak"? It seems fair to assume that a "minor" leak is one that is not detectable by the automatic leak detection system. Since the automatic leak detection system is only capable of detecting 0.5 percent of throughput (page 1-31) a leak of 3,545 barrels per day (@ 709, 000 bpd throughput) could conceivably go undetected. As throughput was increased to 933,000 bpd an undetected leak of 4,665 bpd could occur. This hardly seems like the state of the art technology and is totally unacceptable. NTPC has stated that they intend to fly the right-of-way with a helicopter once every two weeks. If an undetected leak occurred, to the degree described above in a remote area of Montana, over a 10-day period the impact of anywhere from 35,000 to 46,000 barrels of crude oil on the soil and water resources could be disastrous.

⑥ NTPC proposes to cross the Helena valley at a location with shallow groundwater levels. If a "minor" leak were to occur in this area what environmental and economic impacts could be expected? What period of time is required to "flush" oil from the groundwater system? Is there information available relating the size of an oil spill to the size and character of a groundwater system to the rate of recovery? What methods are used to purify groundwater systems where an oil spill has occurred? To what extent will NTPC be fiscally liable for oil spills? How volatile or flammable would an oil spill on the surface be? Could residents living

March 14, 1979
Northern Tier Pipeline
Page -6-

close to the pipeline be expected to pay higher insurance premiums? How will location of the pipeline, in light of potential groundwater contamination and fire hazards from oil spills, affect property values?

⑦ 7. The "directional drilling" process should be examined and addressed as an alternate method of crossing major streams and rivers.

⑧ 8. Further discussion and detail is needed to determine how pipeline construction will be accomplished during irrigation season where irrigated land and irrigation ditches and canals are to be crossed.

⑨ 9. In Montana, conservation districts are charged with administering the Streambed Preservation Act. Accordingly, permits from the districts will be required for each stream crossing. Each conservation district should have a full-time qualified person available to study the proposal and eventually oversee stream crossings that will occur in the district. In districts where personnel are not available is NTPC willing to fund a full-time, qualified person in order to help the districts fulfill their statutory obligations?

⑩ 10. An assessment must be made as to the amount of water needed to hydro test each section of the pipeline. Where will this water be appropriated and at what time of year? Where will dirty water be pumped or how will it be handled before its return to a waterway? Will water be returned to the same watercourse from which it is appropriated?

March 14, 1979
Northern Tier Pipeline
Page -7-

⑪ 11. What are the anticipated geologic and hydrologic effects of the pipeline on areas affected by saline seep? What methods and procedures will be utilized in restoring these areas? What corrosive affects of saline seep on the pipeline can be expected?

⑫ 12. Section 1 of the DES is unclear as to the exact method to be used in checking pipeline welds. Page 1-40 of the draft states that all marine welds will be inspected by x-ray or gamma ray prior to application of the corrosion preventive coating. However, no further mention is made of the methods to be utilized for inspection of the remaining 1,550 miles of pipeline. Will NTPC x-ray or gamma ray each and every weld in the pipeline to insure system integrity?

⑬ 13. Figure 1.4-12 states that "Width B" of Water Course crossings will be 76"-78". This may be an accurate figure for the bottom width of the trench. However, the width at the surface will be substantially wider in most cases due to the unconsolidated nature of sands and gravels encountered in water courses. Sides of the trench will not remain vertical in this type of material but rather at the angle of repose. The impacts of this phase of construction should be expanded in further detail. Will construction work in streambeds cause siltation sufficient to foul irrigation systems?

⑭ 14. Since NTPC, as a common carrier, will have the right of eminent domain to condemn private land for right-of-way or easement can that privilege be involked to condemn public highway, transmission line, pipeline or railroad line rights-of-way for their use?

March 14, 1979
Northern Tier Pipeline
Page -8-

⑮ 15. Page 1-35 of the DES briefly mentions that the quality control on the project will be accomplished by NTPC. I would like to know if NTPC is willing to fund an independent state program for quality control and field inspection similiar to that arranged in Alaska during construction of the Trans-Alaska pipeline?

16. There is widespread belief that the Northern Tier proposal will provide "an embargo-proof crude oil supply to the Northern Tier, upper Midwest and Eastern refineries. . ." (page 8.2-5 Northern Tier Pipeline Project May 1, 1978). This statement is somewhat misleading. True, the pipeline and associated fixtures (pump stations, etc.) from Port Angeles, Washington to Clearbrook, Minnesota can be considered embargo-proof. However, the product for which it is designed to transport is not embargo-proof. Table 1.4-1 on page 1-7 of the Draft indicates that 47% of the oil to be transported in the Northern Tier Pipeline system is from foreign (OPEC) sources. Page 1-4 of the Draft further implies that existing refinery facilities to be serviced by the Northern Tier Pipeline are not presently capable of processing 100% Alaskan North Slope (ANS) crude due to the high content of sulphur and that "utilization of ANS crude consequently depends partly upon the availability of suitable crudes (foreign) for mixing purposes." How will a foreign source embargo
⑯ affect the operation of the Northern Tier pipeline and the refineries it is designed to serve? What are the environmental and economic impacts of retro-fitting Northern Tier refineries to process greater amounts of north slope crude?

March 14, 1979
Northern Tier Pipeline
Page -9-

⑰ 17. Table 1.3-22 on page 1-51 neatly outlines the anticipated costs (May 1978 dollars) of the project. However, it neglects to include the estimated cost of a barrel of oil or gallon of gasoline to the consumer. The DES should compare the estimated costs of the Trans-Alaska pipeline to the actual utlimate cost of that project and the subsequent cost per barrel to the consumer to the NTPC proposal and its alternatives.

⑱ What is NTPC's projected rate of return and how many years will be required to recover the initial investment?

⑲ 18. How many signed "throughput contracts" has NTPC negotiated with Northern Tier refineries?

⑳ 19. I believe that the DES did not assess the political, economic and environmental impacts of an oil spill in the Gulf of Alaska. Increased tanker traffic between Valdez, Alaska and the lower 48 states must be assessed in those terms as well as their vulnerability to sabotage and the capability of military (naval) protection in the event of war.

The United States has for many years, enjoyed an exceptional relationship with Canada. To jeopardize those relations by exposing, not only the entire western coast of Canada, but the Alaska Panhandle and Puget Sound as well, to potential oil spills seems senseless.

March 14, 1979
Northern Tier Pipeline
Page -10-

The Gulf of Alaska, aside from being one of the most treacherous bodies of water in the world, also contains some of the most productive fisheries in the Northern Hemisphere. Increased tanker traffice is a bad risk and will more than likely lead to devastating oil spills.

㉑ 20. How much crude oil is produced in the Norther Tier states and what amount is exported out of the region? How much crude oil is produced in Montana and what amount is exported? To what degree would the curtailment or manipulation of exported crude oil from the state and region offset the Canadian cutbacks?

㉒ 21. Adequate assessment of national need for ANS crude oil is ignored in the DES. The public is entitled to a better accounting of this questio and evidence of a complete examination of records, such as the San Francisco House Oversight Hearings, and the recently released Department of Energy report concerning oil distribution needs.

22. In my opinion, the DES did not adequately address the alternatives to the proposed action. The problem of disposing of excess Alaskan crude oil to Northern Tier markets must be accomplished in an environmentally compatible manner and at the lowest possible cost to the consumer.

The Foothills proposal (Delta Junction - Edmonton), by itself, could eliminate up to four tanker port facilities (Port Angeles, Washington, Kitimat, B.C., Haines and Skagway, Alaska). This alternative would: a) be shorter than the Northern Tier proposal; b) would utilize the existing Alaskan Highway corridor; and c) reduce tanker traffic across the Gulf of Alaska thereby reducing the risk of a major oil spill.

**51 CONT**

March 14, 1979
Northern Tier Pipeline
Page -11-

All factors which would keep increased costs of crude oil products to the consumer at a minimum.

(23) Manipulation and redirection of oil produced in the Northern Tier region must be addressed as an alternative.

Utilization and reversal of the existing Trans-Mountain pipeline and completion of the SOHIO pipeline would also appear to disperse the excess crude at a lower cost than the proposed Northern Tier system.

23. Construction of the Trans-Alaska Pipeline System (TAPS) from Prudhoe Bay to Valdez was authorized by the U.S. Congress in 1973. The TAPS was approved on the basis of National Security and National Energy Independence considerations during the height of the mid-east oil embargo. In early 1973, the U.S. House of Representatives and the U.S. Senate held hearings on the proposed TAPS. At those hearings, oil companies involved with and/or supplying the TAPS system assured Congress and the American people that if the pipeline were built there would not be a surplus of Alaska North Slope crude on the West Coast.

A mere six years later, we are being asked (told) to approve (and pay for) a multi-billion dollar pipeline that, we are told, is needed in order to gain energy independence and dispose of 500,000 bpd of "surplus" ANS crude.

(24) How can the United States gain energy independence with a refinery and subsequent pipeline system that requires 47% foreign source crude oil in order to function properly?

March 14, 1979
Northern Tier Pipeline
Page -12-

(25) How and where is the present ANS crude "surplus" being disposed?

In conclusion, in my opinion, the DES was very vague and discussed impacts on the human and natural environment in a superficial manner. Primarily due to the significant lack of baseline data (soils, water, vegetation, wildlife, etc.) on which sould evaluations and recommendations are based. At times, it seemed as if there were an attempt to massage, conceal or ignore pertinent facts and conditions so as not to have an adverse affect on the proposal. The public deserves and demands better.

Thank you for the opportunity to comment.

Sincerely,

Joe Murphy

RE: Hearings on N^orthern Tier Proposal

Gentlemen:

Due to a death in the immediate family, I was not able to attend the hearings here in Port Angeles. I have read the media accounts and take exception to remarks made by State Representative Andrew Nesbit, (r) of Sequim. Quote: "If you travel through my district like I do, you'd know the entire 24th district is opposed to the project".

That statement is inaccurate, lucus a non lucendo and, pardon the expression, stupidly submitted.

I, too, have travelled this district many times from one extreme to the other and find that perhaps a majority of the citizens in this district don't care one hoot one way or the other about an oil port location. There is a vocal minority group, centralized in Clallam County, particularly in the city of Port Angeles who are opposed to the oil port and to about every other potential development. This minority group would like to speak for the entire 24th legislative district as well as for the bulk of this counties citizenry. Such however, is not the case.

Substantiating facts prevail. OPERA did a complete and thourough study on the environmental and economic aspects of the proposed Northern Tier Pipeline route, during that study, it was determined that the majority of the citizens of this county did favor the oil port facility.

A straw vote, taken within the limits of this city, conducted principally by anti-oil port factions within the county court house, did show an opposition to the facility, however, this was not a county-wide vote and did not reflect the feelings of the majority of the voters.

Yours very truly,

Don McDonald

Oral Testimony Presented at the 13 March 79 Public Hearing in Olympia on the Northern Tier Pipeline Company's Crude Oil Transportation System Draft Environmental Statement

My name is Pam Miller. I am a field biologist and have studied the Puget Sound area during the past four years.

The state of Washington is being asked to sacrifice many of its natural resources in the name of serving the national energy needs. The full extent of these resources is not given in the existing environment section of the Environmental Statement (ES). The extent of adverse impacts to these resources is also not well described. The ES states that "a description of all the resources involved is so complex that a clear picture of the potential impacts could not be drawn." As it is, a clear picture of the potential impacts still is not given in the ES.

(1) The inadequacy of information on marine resources is exemplified by the map addendum, frequently refered to in the text as a place to find more information. The maps are rarely referenced or explained through a key. The marine mammal and waterfowl concentration maps are vague and inaccurate. What is a waterfowl concentration area? Many of the important harbor seal haul out and pupping areas at river deltas along the Hood Canal are not shown.

(2) The maps are not detailed enough to be able to assess the potential impacts to the rivers and estuaries on the Hood Canal. In particular, the pipeline is proposed to run very close to the Hood Canal shoreline between the Duckabush and Hamma Hamma Rivers, but how close? It is impossible to assess the potential damage to salt marshes and other components of the estuarine systems in these areas without better maps.

(3) With either the proposed pipeline route around the Hood Canal or the cross Sound alternative, there would be serious impacts.

The state of Washington is expected to surrender the quality of its marine environment of Puget Sound for this crude oil transportation system, through high risk of devastating damage from oil spills, as well as chronic pollution. The ES states "there will be oil spills." "Small spills less than 100 gallons during oil transfer operations would be fairly frequent. It is likely they would all be contained and cleaned up." Has this been done successfully at other ports around the world?

The ES states that the risk of oil spills was derived from historical in-transit tanker spill rates. But has there ever in history been this much petroleum shipment? Or tankers this large? Or this much traffic on the Strait of Juan de Fuca and all Washington state waters? These factors must be taken into account in determination of oil spill risks. Also, the additional risks of spills from fuel barges necessary to the system, must be shown. The risks for spills between 100 gallons and 2000 barrels of oil also must be determined.

(4) The ES mentions that there would be restrictions on bilge or ballast pumping in Port Angeles Harbor. Even if ballast pumping wasn't done in the vicinity of the harbor, it could still be done in the Straits, and thus affect the water quality of the Sound. And how will these restrictions be enforced?

(5) The environmental effects of similar ports which already exist throughout the world must be described and referenced. This must include data on chronic pollution associated with ports, as well as tanker spills.

-2-

In addition to the impacts to Washington state resources, there would be serious impacts from the oil port operations at Port Angeles to nationally important and designated areas, the Dungeness and Smith Island National Wildlife Refuges and Olympic National Park.

(6) The ES states that habitat losses and disturbances on Green Point would cause species inhabiting and frequenting the site to relocate. Throughout other sections of the ES describing the pipeline route this relocation idea is also given. However, the concept of carrying capacity for habitats must be applied to these discussions. When habitat is destroyed the organisms that depended upon it cannot simply go somewhere else. The individuals and populations of many species will be harmed or destroyed.

(7) Resources which provide livlihood for thousands in the state would be sacrificed in the long run; shellfish, commercial and sport fishing and the tourist industry. These valuable resources could not be replaced in 20 years, once the economic lifespan of the pipeline is over. After 20 years will we find that the environmental costs have been worth it, with such high risks to the food resources of Puget Sound and Hood Canal? The economic costs to the state resulting from the project must be better described, including losses from degradation of marine and aquatic resources, changes in the quality of life, and effects on human health from hydrocarbon emmissions and petroleum contamination.

(8) The people of Washington will not reciéve the benefits of energy from this energy facility. In fact, it would place increased demand on the electricity supplies of the state. The ES admits that this is an unsolved problem. This is a serious issue that must be more comprehensively addressed.

(9) The need for this facility must be substantiated in the ES with more data. The ES states that solar energy would only slightly increase by 2000. This assumption is not supported and is very biased. Solar technology exists and may be implemented, if the economic obstacles were lessened. The potential effects of implementation of solar energy on the total energy needs in the Northern Tier states must be included.

For these reasons I oppose transshipment of crude oil in Washington State waters.

U. S. Bureau of Land Management
Dick Miller, Environmental Impact Statement Coordinator
Portland, Oregon 97232

Gentlemen:

As property owners at Low Point, a geodetic survey marking located some 15 to 18 miles west of Port Angeles on the Straits of Juan de Fuca, we strongly and adamantly oppose the possible construction of an oil port at this location as proposed by Trans Mountain Pipe Line, Ltd.

With reference to the attached newspaper clipping, we sincerely and respectfully advocate and encourage the operation of a rail plan which would not cause adverse problems or restrictions.

Regardless of the relatively small population in the Low Point area, it is an established right of all individuals to protect their property. Notwithstanding our individual rights, every consideration should be given to the welfare and survival of the wildlife, fish and game that would unmercifully be jeopardized by the construction and operation of an oil port at this site.

The almighty dollar speaks loudly and carries untold precedence; however, we are hopeful that, as ordinary citizens and property owners, we still have the right and privilege of protecting and defending our property. Obviously, we have chosen this location because of its beauty, wildlife and general peaceful environment, and it is more than somewhat distressing to think that all this could be destroyed by big business with their unending power and wealth.

Please, where can we turn for understanding, consideration and assistance in our endeavors?

Sincerely,

D. E. Hermann

21 March 1979

Mr. Albert Leonard, Manager
Northern Tier E. S. Team, BLM
700 N.E. Multnomah, Suite 1250
Portland, Oregon 97230

Dear Mr. Leonard:

(1) Attached is the testimony submitted by Dr. Oldaker at the Juneau hearing on 19 March. The sentiment expressed, strongly opposing the development of Southeastern Alaska as a major petroleum shipment lane, reflects the overwhelming feelings of our Chapter and that of most other residents of the Juneau area who are aware of this plan.

We would appreciate advance notification of further hearings or other developments on this situation.

Sincerely,

Frederick F. Wright
Frederick F. Wright
President

COMMENTS: NORTHERN TIER PROJECT
Bureau of Land Management Hearing
Juneau, Alaska, 19 March 1979

Good afternoon, Mr. Chairman, I am LAWRENCE LEE OLDAKER, Division of Education Coordinator, University of Alaska, Juneau and a director of the Taku Chapter of the Alaska Conservation Society. Thank you for permitting me the opportunity to express my comments, independent of the University but related to the interests of the Conservation Society.

Preface remarks. This public hearing and the manner in which the NORTHWEST ENERGY COMPANY proposal has been analyzed raises troublesome and fundamental issues:

1) Has there been adequate publicity on this meeting to generate full discussion?

2) Will the revised environmental impact statement address the Skagway issues?

3) Does the urgency of petroleum needs in the midwest offset environmental and economic interests of Alaska?

Basic thesis. My remarks relative to the NORTHWEST ENERGY COMPANY proposal ~~an~~ are basically cautionary. The movement of crude oil from Valdez via tanker through Southeast Alaska to Skagway for pipeline delivery to the midcontinent lacks any sustaining economic benefit to the region and state. It also poses several environmental hazards. Another routing scheme, the Trans-

-2-

Mountain, may prove to be more cost effective and less environmentally disruptive. Major points to support this thesis are as follows:

1) Tanker traffic and terminal operations in Southeast Alaska would threaten major "renewable" resource industries, fisheries and tourism. The salmon catch from the Icy Strait - Chatham Strait - Lynn Canal area is valued at $13,146,000; an additional $561,000 is realized in King and tanner crab sales. The economic damage of potential oil spills in this fertile fishery area is a threatening spectre. Although 430,000 tourists spent $175,000,000 in Alaska-at-large during the preceding year, the Panhandle area witnessed a large share of financial benefit which was attributed to visitors seeking wilderness-oriented pleasures. (Please see enclosures for details.)

2) Large-scale tanker movement in Southeast Alaska would conflict with gill netters, purse seiners, trollers, tour boats, and pleasure crafts.

55

3) The physical and climate conditions offer further transportation problems within the inside waters. Narrow, rocky channels; widely varying tides and stream currents; and high winds add to the problem. Taku winds of 30-70 knots per hour for periods of two to three weeks are common. Oil spill recovery measures appear to be ineffective in waters with strong current and wave action above two to three feet.

4) Skagway, the focal point of the proposed NORTHERN TIER route, would receive a brief economic boost during the terminal development phase but could not look to any degree of monetary gain in post-construction years. Problems in building a pipeline over the White Pass are legion.

Table ~~2~~7-1. Average annual value to fishermen of commercial fisheries in the Icy Strait/Chatham Strait/Lynn Canal area. See Tables 2-3 to 2-6 for additional detail.

| | Icy Strait | Chatham Strait | Lynn Canal | Total |
|---|---|---|---|---|
| Salmon | $6,833,000 | $2,830,000 | $3,483,000 | $13,146,000 |
| Herring | | | | |
| Halibut | | | | |
| Sablefish | | | | |
| King crab | 112,000 | 70,000 | 20,000 | 202,000 |
| Tanner crab | 276,000 | 43,000 | 40,000 | 359,000 |
| Dungeness crab | | | | |
| Total | 7,221,000.— | 3,943,000 — | 3,543,000 | 13,707,000 |

Division of Tourism, Juneau

-3-

Summary. Accepting the perceived need to place Alaskan oil in the midwest as a real concern, we believe any of the other alternatives would be more beneficial to the nation, state, and region. The potential for long- and short-term hazards to the Southeast Alaska panhandle should dissuade the selection of the Skagway tanker-pipeline route as the means to send oil to the nation's heartland. Thank you again for permitting the expression of this view.

March 20, 1979

Bureau of Land Management
Northern Tier Project

It seems to me that you should consider the proposed Northern Tier Crude Oil Transportation System in all of its ecological impact.

For instance, it is wrong to make the excuse that the surplus of high sulfur crude oil from Alaska requires another pipeline, for that would be the perpetuation of an error which was damaging environmentally and expensive economically. This money could be spent to encourage the production of ethanol from biomass for this would provide jobs and an alternative for crude oil.

The demand for jobs should be more carefully considered. It is wrong to permit immigration if there is unemployment as each nation is responsible to use birth control to adjust its need for babies to resources and jobs available. The crowded overpopulations of the world will continue to invade and occupy the U.S.A., ignorantly dumping their children on the welfare system of the U.S.A., until a firm stand is taken on the truth that the pursuit of employment does not constitute a vested right to ruin the environment and wildlife habitat. It has been proven on the other hand, that more jobs are generated with protection of the environment. The pipeline for the northern tier is an unnecessary boondoggle, as was the Alaskan pipeline; for there are ever-increasing demands for alternatives to the automobile which kills, pollutes, and bankrupts and is called mankind's greatest blight.

The plea for an "All-American" pipeline is specious as the threat of tanker spills in the Straits would mean an American-Canadian catastrophe ecologically. There is a question as to just what is meant ~~by~~ on page 38 of the "Summary", for there is the statement that the basic purpose of the pipeline is to transport Alaskan and foreign crude oil? Please, gasoline rationing is better

Bureau of Land Management
729 N.E. Oregon St.
Portland, Oregon 97208

Gentlemen:

Deficient in scope, was the prime message the Daily News attempted to convey through their reporting of the Bureau's hearing at Port Angeles March 16, 1979 regards the oil port and the pipeline planning of Northern Tier.

How any project the size and scope and magnitude of this pipe line could be otherwise is beyond me. The ramifications of the thing are many and for anyone or any group of experts to be able to identify all aspects would be to make them just a little better than perfect. To my knowledge no human has yet attained perfection.

Each day I begin my own work deficient in something. Through resourcefulness and adaptability I usually end with some satisfactory accomplishment. I am sure Northern Tier would attempt to do a good job. They have to.

The line is needed, that is not the question. Just how quickly it can be finished seems to be more pertinent to the welfare of this nation.

Sincerely,

Henry Bechtold

ACTION ____ FILE ____

Mr. Charles E. Steele
Bureau of Land Management
P.O. Box 1229
Dickinson, ND 58601

Dear Chuck:

I have reviewed the draft environmental statement for the Northern Tier Pipeline Company and the effect it may have on the North Dakota Forest Service. I hope it is not too late for comments.

① The pipeline as drawn will be going within a mile of the State tree seedling nursery at Towner, North Dakota. We, of course, do not wish to see the pipeline any closer. The Nursery and recreation area are located in Section 31, Township 157, Range 75 just north of the proposed pipeline route. The U.S. Forest Service also has land in Section 31, 32, and 33 of the same township in McHenry County. If the proposed pipeline should be moved any further north, it would cross the Nursery and interfere with tree production. It would also cross the State recreation area near the Nursery.

The Nursery and recreation area must be avoided in construction of the pipeline.

Sincerely,

Walter Pasiczynk

Comments of N.D. Game and Fish Department
on the EIS Regarding the Proposed
Northern Tier Pipeline

1. We note from the alignment sheets in the Map Addendum that the proposed pipeline is parallel to other transportation systems in many places. We endorse this "utility corridor" concept as the least environmentally damaging in many cases.

① 2. We note on p. 3-74 the assertion that "the state of North Dakota has classified the Little Muddy River Class II." This is somewhat misleading. The State Health Department has rated the stream as II, based on its suitability for direct use by humans. The Game and Fish Department, however, has published another ranking of permanent streams in North Dakota, based upon the fishery present and aquatic habitat considerations. Under this system we have ranked the Little Muddy River as 1, highest value, due to the presence of high forage, fish production and other factors. Other streams crossed by this proposal in or adjacent to North Dakota which we have ranked are the Missouri River (rank 1), the White Earth River (rank 1), the Des Lacs River (rank 2), the Souris River (rank 1), Egg Creek (rank 1), the second Souris crossing (rank 1), Big Coulee (rank 1), the North Branch of the Turtle River (rank 4), the Turtle mainstem (rank 2), and the Red River (rank 1). The fact that impacts to these streams from the proposed action are considered in this EIS points up the need for extreme care to be taken to minimize adverse environmental effects. There are also numerous intermittent streams and wetlands in the path of the proposal. Some losses would be certain to occur and adequate mitigation should be provided for in the work plan.

② 3. We are disturbed to note (p. 3-84) that an oil spill of 4,640 barrels per day could go undetected by the remote sensing system, thus depending for detection upon the biweekly overflights required by federal regulation. The potential is thus there for a spill of upwards of 65,000 barrels of oil to occur before detection. Given that this proposal would traverse North Dakota's prairie pothole country, such an occurrence could be catastrophic. Is this the best level of detection we can hope for? We will be quite interested in the contents of the spill contingency plan (p. 1-55) when it is developed, how it will apply to North Dakota, and what unavoidable impacts will result from spills.

4. It is perhaps understandable that specific construction start-up times, soil segregation and seeding techniques, mitigation for lost wildlife habitats such as woodlands and wetlands, and specific measures to minimize sedimentation at stream crossings, cannot be detailed at this time. ③ We hope we will have the opportunity to contribute to the resolution of these issues at some later date, as during the permitting process. We would like to make the following general comments, however:

   ④ a. There seems to be no provision for segregating topsoil other than in irrigated or prime farmland areas (p. 1-44). We strongly recommend that such "double-ditching" be done over the whole route, at least in North Dakota. Seeding success after backfilling could depend upon this.

   ③ b. Losses of woodlands, especially riparian habitats at stream crossings, for the life of the project is a serious matter for a state that is very near to having fewer trees than any other state in the Union. Our usual recommendation is replacement on a 2 for 1 basis, if not on site, then somewhere close by.

59 CONT

③ c. We recommend avoidance of wetlands wherever possible. If it is necessary to disturb a wetland, we strongly recommend adequate mitigation, the nature of which would be jointly agreed upon.

d. Seeding mixtures, planting times, topsoil respreading, grading, and maintenance techniques will all have a bearing on the success of the revegetation effort. Again, we hope to be able to present our views on these issues when it becomes appropriate to do so.

e. Impacts upon duck production and other aspects of wetland habitats may be able to be reduced if any necessary disturbance is carefully timed. Similarly, stream crossing impacts can be minimized at low flow times. We are prepared to supply technical assistance when needed in these areas also.

March 23, 1979

Bureau of Land Management
Oregon State Office
129 NE Oregon Street
Portland, OR 97208

Dear Sirs:

This Department wishes to make the following comments concerning the Draft Environmental Statement of the Crude Oil Transportation System from Port Angeles, Washington to Clearbrook, Minnesota, as proposed by the Northern Tier Pipeline.

① It is understood that this is a draft environmental statement and that the route proposed therein is not an exact route. However, with the level of detail provided to us in this draft, it appears that the pipeline could have some impact on areas that we have interests in. The communities of Berthold, Knox, Leeds, Lakota, and Petersburg all have outdoor recreation facilities within or adjacent to their boundaries which were partially funded with money from the Land and Water Conservation Fund Act of 1964. The 6F provision of this Act states that projects funded with this money will remain in outdoor recreation use in perpetuity. A pipeline crossing of these areas would not be permissible without replacement of the land affected by such a crossing.

This Department is also responsible for the State Nature Preserve System. A potential inclusion to this system lies within the pipeline corridor. It is called Pleasant Lake Woods and is located in Sections 8 and 9, Township 155 N., Range 71 W. Although there are no regulations making it mandatory to avoid such an area, we would hope to work closely with the Northern Tier Pipeline Company to determine if this area can be avoided.

Also, Turtle River State Park, near Arvilla, is located within the corridor boundaries. State parks are held to be exclusion areas for utility crossings and as such, no crossing through the park would be permitted.

② Some of the more general statements concerning recreation in the draft environmental statement are incorrect and should be pointed out. The errors are contained in Chapter 3. On page 117, it is stated that "No areas of critical importance to recreation would be crossed by the 2-mile wide study corridor." Since the corridor crosses the prairie pothole region, which is a major area of duck production, it does have implications and impacts on an area which is critically important to some types of recreation, especially waterfowl hunting. On page 118, it is stated that since national wildlife refuges do not allow public use, they are not important to recreational hunting or nature-related activities. The fact is that some public use is permitted on these refuges and they are critically important to a variety of recreational activities.

③ Also, on page 118, the Devils Lake Recreation Area is identified as being southwest of Minot. This area is actually located east of Minot. It is likely that the Devils Lake Recreation Area will receive additional use during the construction phase of the project. My question at this point is: Was only the location of the Devils Lake Recreation Area incorrectly identified, or is there a recreation area southwest of Minot which will also be impacted?

In Chapter 4, page 8, it is stated that no mitigating measures concerning recreational resources have been proposed by the applicant. We feel that it is Northern Tier Pipeline Company's responsibility to work closely with all agencies concerned with outdoor recreation resources and to provide mitigating measures in those cases where it is determined to be necessary.

If you have any questions concerning any of the above comments, please contact me at this office.

Sincerely,

Terry Vibeto

STATE INTERGOVERNMENTAL CLEARINGHOUSE SUPPLEMENTARY "LETTER OF COMMENT" ON PROJECT REVIEW IN CONFORMANCE WITH OMB CIRCULAR NO. A-95

To: Bureau of Land Management, Oregon State Office

STATE APPLICATION IDENTIFIER: 7901119034

Mr. Frank Hamerski, Acting Project Manager
U.S. Dept. of Interior
Bureau of Land Management - Oregon State Office
P.O. Box 2965
Portland, Oregon 97208

Dear Mr. Hamerski:

Subject: Draft Environmental Impact Statement for the Crude Oil Transportation System.

This Draft EIS was recieved in our office January 11, 1979.

The above referenced draft EIS has been reviewed through the North Dakota State Intergovernmental Clearinghouse in compliance with Office of Management and Budget Circular No. A-95 and/or North Dakota Executive Order No. 48. Previous comments were forwarded to you with a "Letter of Comment" dated January 15, 1979 and "Supplementary Letter of Comments" dated February 22 and 26, 1979, March 5, 1979. Since then, additional comments have been received from: North Central Planning Council.

This letter and the attached comments constitute the further comment of the State Intergovernmental Clearinghouse. To further document your compliance with Office of Management and Budget Circular No. A-95, this letter, the attached comments and your response to those comments should be made a part of your proposal.

Please use the above SAI number for reference to the above project with this office. Your continued cooperation in the review process is much appreciated.

Sincerely yours,

Bonnie A. Banks

OLYMPIC PENINSULA AUDUBON SOCIETY
P.O. Box 502 - Sequim, Wa. 98382

March 22, 1979

Statement presented by Harvey Kailin, Chairman, Conservation Committee, Olympic Peninsula Audubon Society at the BLM Public Hearing In Port Angeles, Washington, March 15, 1979

My name is Harvey Kailin, representing the Olympic Peninsula Audubon Society, an organization of some 300 adult members. Because the interest of our organization is in the natural environment, we are concerned about developments which could have serious environmental consequences. Our comments will be, for the most part, general - various specifics have been or will be commented on by others, including No Oilport, Inc., whose position on the Northern Tier project we support and whose questions about it we also wish answered. A number of our members have been working with the Citizens Task Force to provide expertise on the flora and fauna of the area, and on various environmental factors involved in the Northern Tier project.

In reviewing the BLM's DES, we find it has significant limitations. For example:

1. Congress mandated an earlier completion date for the BLM study than was consistent with doing an adequate job. BLM officials as well as others previously have pointed this out. The earlier testimony here confirms that conclusion.

2. Another limitation, not the fault of BLM, is that Northern Tier's changing specifications have made it difficult to know just what to evaluate. For example, in January Northern Tier designated a new primary route through Montana. In this State, at this late date, a major change in pipeline route apparently is imminent, according to Northern Tier officials. Will the pipeline go around Hood Canal and then across the State, or will it proceed by submerged pipeline through the Strait of Juan de Fuca, across Whidby Island, and then eastward? Different routes of course involve different environmental impacts.

① And just what size operation is involved in this project? The bulk of the DES statistics deal with a 709,000 bpd or a 933,000 bpd operation. But late in the DES we learn that expansion of the project to a 3 berth, 1.23 million bpd operation is possible. Shouldn't an operation of at least that size be used as the basis for determining impacts? Senator Jackson talks about the need to step up Alaska production to 2 million bpd - what effect would that have on Northern Tier's operation? And Northern Tier talks about access to 50 refineries with a capacity of 3.6 million bpd. Clearly, it would not be responsible to base conclusions on an initial size of operation, with so many open ended possibilities on the horizon.

② 3. Another major limitation of the BLM study is a reflection of the limitation in its scope. An oil superport doesn't exist in isolation - it is a magnet for other developments, particularly those in the petrochemical field. For example, a business consortium recently announced plans for building a large refinery to be supplied from oil reaching this area through the superport. Once a large crude oil source exists, it is almost a certainty that refineries and petrochemical plants which use refinery products as their feedstock will be sited close to the superport. Once a port is sited, the pressure to get approval for such plants will prove to be inexorable. This prospect was summarized in a study made a few years ago by the Puget Sound Economic Development Council in anticipation that such an oilport would be sited here. The study study pointed out that the development of related petrochemical industries is a logical accompaniment to an oilport. Not only would the port be the source of the industry's feedstock, but it would be an economical location from which the industry's finished products could be transported to the entire west coast area. What would be the impacts of such developments? Aren't they likely to be greater than those of the oilport and pipeline? Isn't the consideration of their impacts required for a meaningful impact statement?

③ What are some of the important places or locations in this general area which could be impacted by the Northern Tier project. The borders of the Olympic National Park of course are very close to the port, tank farm, pipeline, and to future industrial developments based on the oil supply this project would make available. The Park recently has been designated by UNESCO as one of a limited number of biosphere reserve areas. The Park possesses an unusually diverse collection of plants and animals. It has the potential to serve as the base for reconstituting genetically depleted areas. It is highly questionable whether the model used for determining deterioration of air quality, as noted by the Park Superintendent, permits an adequate evaluation of the project's impact on the Park. This limitation, plus the others I referred to earlier, raise serious questions about what the consequences will be for the Park.

④ The limitation of the DES also are pertinent to questions about water quality, which would be affected by oil spills, chronic or otherwise, resulting from a large scale movement of tankers, tanker unloading operations, the barge traffic necessary to provide bunker fuel for the tankers, the operation of the pipeline, and the operations of petrochemical industries which can be expected to be sited near the oilport. How many rivers and watersheds crossed by the pipeline will be impacted? What will be the effect on Dungeness Spit and Harbor, the largest Federal waterfowl sanctuary in the State.

⑤ With regard to Dungeness Spit there is an additional problem, as its continued existence depends on its being fed by the easterly flow along the Strait carrying materials from the bluffs which border the Strait. Interference with such movement, by pipelines from the port, with associated bulkheads or other devices needed to protect the pipelines, could interfere with the water flow and prevent the buildup to the Spit necessary for its continued existence. Experience with Ediz Hook, where the natural buildup of that spit was interferred with and where costly maintenance has been necessary to preserve the harbor are a warning of what could happen to Dungeness Spit.

⑥ Our membership includes a number of individuals with expertise in the flora and fauna of the area. They have identified a number of rare and endangered plants on the Olympic Peninsula, including:

> Calypso bulbosa, Eriophyllum linatum var. achilleoides, Erythronium oregonum, Hemitomes congestum, Lipidium virginicum var. menziesii, Scirpus cyperinus, Sedum lanceolatum var. rupicolum, Botrychium virginianum, Chrysolepsis chrysophylla, Euarophyton austiniae, Plantago macrocarpa, Bromus vulgaris var. eximus, and three Clarkia amoenas (var. pacifica, var. caurina, and var. quadrivulnera), Pucinellia pauciflora var. pauciflora, Sheperdia canadensis, Abronia umbellata var. acutalata (found on Ediz Hook), Bromus sitchensis var. sitchensis, and Juncus gerardii.

⑦ As to bird life, peregrine falcons have been sighted at Dungeness Bay. There are roosting trees for them near Jamestown Beach. Birds of concern from the Audubon 'blue list' (birds which are threatened) and which are present on the Olympic Peninsula include:

> The Redneck grebe, the Western Grebe (both highly susceptible to oil damage since they sleep on the water), the Canvas Back, Sharp shin Hawk, Cooper's Hawk, Marsh Hawk, Osprey (a summer resident with a couple of nest sites known on the northern part of the Olympic Peninsula), the American Kestral, the Pigeon Hawk, the Common Tern which migrate through Dungeness Bay, the Short eared Owl, the Hairy Woodpecker, the very rare Western Bluebird, the Yellow Warbler, and the Warbling vireo.

⑧ We feel that the DES doesn't provide an adequate basis for weighing the environmental costs to the public, including costs to fishery resources, to the recreational industry potential of the area, to the Park, to the rare and endangered plant and bird species, etc. or for comparing them with possible benefits of the project. In other words, a comprehensive cost-benefit analysis, based on a thorough environmental study, is needed.

⑨ The DES also has an inadequate treatment of need for the project and of alternative ways of meeting need. It is unfortunate that the Department of Energy study relating to those matters was delayed and its findings not adequately reflected in the DES. It is important to get an objective measure of need, and of the extent to which alternatives such as redirection of indigenous supply in the northern tier states, increase of trade-off arrangements, improvements in existing oil transportation facilities, new oil finds, etc. can meet the need.

In summary, we do not feel that an environmental statement can serve the needs for which it is designed if:

1. It doesn't provide an adequate basis for evaluating environmental impacts.
2. It doesn't provide a comprehensive cost-benefit analysis.
3. It doesn't thoroughly explore need and alternatives for meeting that need.

One final observation. The Audubon Society believes that there is an important principle to be followed in connection with developments such as the proposed one. That is that developments such as the Northern Tier one should be located in already impacted areas rather than in relatively unspoiled ones such as represented by this area. We find no compelling case, nor has the DES developed one, for violating this principle.

Bureau of Land Management
Oregon State Director
Northern Tier Project
Room 1250, Lloyd Building
700 N. E. Multnomah
Portland, Oregon 97232

Dear Sirs:

I oppose the Northern Tier Project for the following reasons:

① 1. A. Draft Environmental Statement reviewed only ways of moving the Alaska crude oil to Northern border and Midland States and neglected other potential solutions to the overall crude oil supply problem in the central U. S.

② B. Failed to consider the modernizing of west coast oil refineries not geared to refine Alaskan crude oil.

③ 2. Northern Tier Pipeline Company has failed to mention in case of an oil spill who would be responsible for cleanup and restoration costs.

3. Fear that the Northern Tier Pipeline, if approved, would create a new right-of-way corridor that in time likely would attract additional energy transmission facilities.

Northern Tier Pipeline would not solve the energy problem, but just prolong it and create many new problems for Montana and its citizens.

Respectfully,

Robert Barker

BLM - Northern Tier Project
Room 1250, Lloyd Building
700 N.E. Multnomah
Portland, Oregon 97232

Gentlemen:

After having attended informational meetings chaired by employees of the Northern Tier Pipeline Company, after having attended several more meetings sponsored by concerned local citizens, and after having read everything I could find on the proposed Northern Tier Pipeline, I feel that I must express my opposition to the proposed line.

It would take hours of my and your time to spell out in great detail each of my objections. I do wish, however, to list a number of my objections:

1. The D.E.S. on the proposed Northern Tier Pipeline states that a "surplus" of Alaskan crude exists on the West Coast. This "surplus" is presently being shipped by way of the Panama Canal to midwestern refineries.

2. Other means of shipping this "surplus," both existing and proposed, would prove to be more efficient, less expensive, and have less adverse environmental impact.

3. Changing present marketing patterns would alleviate the shortage in the Mid-West.

4. Why build Northern Tier Pipeline, whose daily capacity is projected to be over 900,000 barrels per day when the projected shortage in the Mid West by the year 2000 is expected to be only 400,000 barrels per day?

5. The electric power requirements for pumping the oil through the proposed line would exceed twice the capacity of Hungry Horse Dam. These requirements would place an additional strain on an already overworked Northwest power system.

6. The electronic sensoring equipment proposed by N.T.P.C. would allow an undetected leakage of 1,340 barrels per day.

7. Construction of the proposed N.T.P.C. would set a corridor precedent along the entire route. Montana does not need any additional power corridors to mar its Big Sky.

① 8. The Draft Environmental Statement completely fails to address the issue of the effects construction and haulage would have upon roads and highways along the route. No requirements have been made to prevent damage to these roads nor to restore them to their present state. Just who paid for damages to the Alaskan highways?

② 9. Sections of the route parallel the Nine-Mile fault. Their geologists "assure" us that this fault is inactive. Will the N.T.P.C. also assure us that they will be financially responsible for all damages to private property caused by spillages if faulting ruptures the line?

10. The proposed pipeline would have an adverse effect on the rural, scenic lifestyle chosen by those along its route. I chose a homesite for the same values that the proposed pipeline and power corridor would destroy.

③ 11. The proposed pipeline is one of many misdirected, piecemeal attempts to solve or alleviate a national energy crisis. What we really need is a clearcut national policy of conservation, and not another means of expediting waste.

④ 12. The right-of-way requirements exceed that of the Alaskan Pipeline, which is larger in diameter than the proposed N.T.P. In addition, the Mineral Leasing Act of 1920 stipulates that the right-of-way for pipelines through federal lands should not exceed 54'.

⑤ 13. The B.L.M. Draft Environmental Statement fails to address the potential impact the proposed pipeline might have upon perched or shallow water tables which are important supplies for livestock and irrigation. Will N.T.P.C. pay for any financial loss incurred if disruption of such supplies occur?

14. The proposed surveillance program of one N.T.P.C. employee acting as an environmental inspector per construction spread is obviously inadequate.

⑥ 15. The social impact assessment within the D.E.S. does not comply with the ground rules for such assessment.

⑦ 16. The proposed pipeline passes through many homesites and would result in an unfair devaluation of residential property. Would the N.T.P.C. compensate homeowners for such loss?

⑧ 17. The burden imposed by construction employees dependents upon local school systems would not be offset by any additional tax revenue upon the proposed line. Overcrowding presently exists in the Missoula, Frenchtown, and Alberton systems.

As a homeowner in the area through which the proposed pipeline would pass, I am naturally concerned for my own quality of life. However, I am not just saying, "find a different route." I am saying that the Northern Tier proposal should be carefully examined in terms of need and efficiency, and that its horrendous costs (amount of energy used in its construction, environmental and social impacts) should be carefully considered before we allow an "energy crisis" to frighten us into unwise decisions.

Sincerely,

William Z. MacDonald

BLM - Northern Tier Project
Rm. 1250, Lloyd Building
700 N.E. Multnomah
Portland, Oregon 97232

Gentlemen:

This is our input to BLM in regard to Northern Tier Pipeline proposal.

From our reading and study, we maintain that the Northern Tier proposal is ill advised and too generally opposed for it to be accepted as a viable route. In other words, popular opposition is too great.

The present Alaska Pipeline (Prudhoe Bay-Valdez) is considered widely as an ill-advised and costly mistake -- financially and environmentally — and we see no reason to extend and compound that costly and ill-advised error by doing exactly the same thing again, ie, building a pipeline from Port Angeles to Clearbrook Minn.

The residents of Puget Sound, and Port Angeles in particular, are against constructing a super oil port in Port Angeles. The risks to the Puget Sound industries and amenities are obviously too great. Their opinions should, as a moral issue, be considered. They're citizens, too.

The logical alternative is the route that should have been built in the first place -- the route that follows the Alaska Highway down from Delta Junction. This route, too, would terminate in Minnesota and the other central states where the oil was needed in the first place. This route is the least disruptive environmentally; and it makes the most business sense.

Sincerely yours

Mr. and Mrs. Peyton Moncure

CLEARWATER SOIL AND WATER
CONSERVATION DISTRICT

MINNESOTA
SOIL AND WATER CONSERVATION DISTRICTS

March 23, 1979

Bureau of Land Management
Oregon State Director
Northern Tier Project
Room 125, Lloyd Building
700 N.E. Multnomah
Portland, Oregon 97232

Dear Sirs;

❶ The Clearwater Soil & Water Conservation District would like to make two recommendations concerning the proposed NTPL through Clearwater County.

1. They would recommend that at river on stream crossings, construction companies open stream banks only for the shortest period of time possible. Past construction of pipelines has left banks open for such long periods that considerable washing occurred over a summer and possibly caused a sizeable fish kill in our area.
2. They also recommend that the construction companies do all smoothing, fertilizing, seeding, mulching, and fencing as part of the contact with individual landowners. This prevents the landowner from pocketing the money and not protecting the soil from erosion, particularly in forested areas. In addition, it would be more economical in terms of suitable equipment fertilizer, and seed costs. Our office could work with the company and landowners to arrive at an acceptable seeding formula and fertilizer recommendations.

The board would like to commend the NTPL company for providing considerable information on the pipeline and its construction.

Sincerely,

Doug Thompson
District Technician

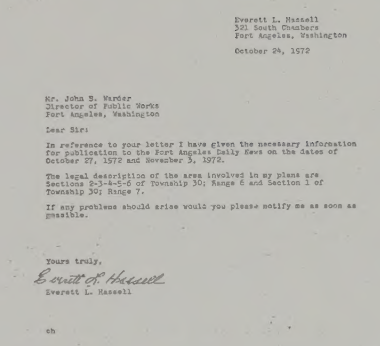
CONT



Everett L. Hassell
321 South Chambers St.
Port Angeles, Wn. 98368

Dear Sir;

I feel there is definately a need for a storage area for logs and containers for salvage of wood chips in your forest today.

There is also a need for an improved truck route around Lake Crescent to help eliminate excess traffic around the Lake. It is also felt it is needed to help reroute truck traffic so it will no longer run through towns and on state highways damaging property and unnecessarily taking the lives of innocent people.

Noise and air pollution will be decreased for the townspeople if the proposed construction of this area is undertaken.

This will also greatly contribute to restoring the marine life and fisheries industries to the same capacity as this area was 100 years ago. This would help create more jobs with an emphasis on the minority groups in the area.. The main emphasis would lean toward the welfare of the Elwha Indians.

Also along this right away we would install up to date rest--side facilities for public use.

Thank you very much for considering my proposal.

Sincerely Yours,
Everett L. Hassell

CONT.

NOTICE OF APPLICATION FOR
SHORELINE MANAGEMENT
SUBSTANTIAL DEVELOPMENT PERMIT

NOTICE IS HEREBY GIVEN that Mr. E. L. Hassell
321 South Chambers Street Port Angeles, Washington
has filed an application for a Substantial Development Permit for constructing a truck road, yards for storage of logs and "TLH" trailers, and solid waste disposal site, along the Strait of Juan de Fuca between Marine Drive, Port Angeles to the Elwha River.

within the Townsite of Port Angeles, Clallam County, Washington. Said development is proposed to be within Port Angeles Harbor and/or its associated wetlands.

Any person desiring to express his views or to be notified of the action taken on this application should notify the Director of Public Works, City of Port Angeles, P. O. Box 711, in writing of his interest, within thirty days of the last date of publication of this notice. Publication dates of this notice are October 27 and November 3, 1972.

John B. Warder
Director of Public Works

March 21, 1979
Skagway, Alaska
P.O. Box 147

Bureau of Land Management
Northern Tier Project
700 N.E. Multnomah
Portland, Oregon 97232

Dear Sirs:

As a resident of Skagway, the proposal by Foothills Pipeline Company to construct an oil tanker docking facility, tank farm and pipeline in Skagway concerns me.

① Skagway is located in a narrow valley, half a mile wide and perhaps two miles long. Steep mountainsides restrict growth.

My concern centers on such a large project as this pipeline coming into such a small area. I am sure that environmental safeguards will be foremost in the company's project to protect the area from the sort of disaster that unfortunately attends thoughts of crude oil transportation.

But the impact of this project on Skagway as we know it today will be enormous. The pipeline will literally make the town over in its own image. I am worried about the social impacts of noise, congestion and strains put on city services. As a public works employee, I know that our town's services are already at capacity.

With proper planning, these impacts may be mitigated to everyone's satisfaction. The construction phase, however, will be detrimental to everyone's quality of life here. Everything, so to speak, will happen on everyone's front step.

Once the pipeline is operating, I am worried about the degree of safety residents of Skagway will have with million-size oil tankers offloading regularly within the city limits. An explosion at the dock might level half the town.

Also, my concern for the large scale of this project includes the prospect of routine tanker traffic in Chatham Strait, Lynn Canal and Taiya Inlet. These are protected waters, but they are at places quite restricted, often prone to gale force winds and extreme tide differentials. Even the most sophisticated oil spill containment equipment would be helpless to prevent serious damage to these waters in the event of a spill. A large spill might ruin southeast Alaska's tourist and fishing industries.

Thanks for considering my concerns. Sincerely,

---

Dear Mr. Leonard:

Enclosed is a copy of a letter we received from Mr. Mark Lewis, Manager of the City of Valdez. Mr. Lewis has expressed his concern over the options identified in your Northern Tier environmental statement.

We request that Mr. Lewis' letter be made part of the record of responses to the draft EIS.

Sincerely,

Jerry L. Madden
State-Federal Coordinator

Dear Mr. Madden:

Re: Northern Tier Pipeline Co.
State I.D. No. 79011806

The City of Valdez is quite concerned about this project as we feel there will be direct impacts upon Valdez, whatever route or method is chosen. We would appreciate our concerns being expressed at the public hearing scheduled in Juneau on March 19, 1979 and submitted to the Bureau of Land Management for their review. Our comments are based upon the following:

1. Valdez is the site of the existing oil pipeline terminal for Alaska crude oil;
2. Our local economy is partially dependant and would be effected by changes in outflow from that terminal;
3. The pipeline presently operates at only 60% capacity (1,200,000bpd) with future expansion of the West tank farm, expanded port facilities and increased jobs for our citizens somewhat dependant upon a decision regarding this project.
4. Alaska crude is presently shipped to the Arco Refinery at Cherry Point (100,000 bpd cap.) north of Bellingham, Washington, the Mobil Refinery (75,000 bpd) near Ferndale, WN., to San Francisco, Long Beach, Los Angeles and Panama. Some small amounts are also sold to the U.S. Oil Refinery near Tacoma. However, the present supply exceeds the refinery capacity of West Coast Refiners by 500,000 to 600,000 bpd. This excess is shipped via the Panama Canal to Golf of Mexico and East Coast Ports. Estimates are that this "glut" will get worse if pipeline capacity is reached in Alaska.

EXISTING REFINERY CONDITIONS - WASHINGTON STATE

(Anchorage Times - 2/7/79)

A. U.S. OIL AND REFINING (time oil) Tacoma - converting to use Alaska Crude 31,900 bpd.
B. ARCO AT CHERRY POINT - 100,000 bpd - built in 1972 for Alaska Crude.

Jerry Madden, State-Federal Coordinator
March 13, 1979
Page 2

C. SHELL - 91,000 bpd. - only uses 10% of Alaska Crude.
D. TEXACO - Anacortes - 78,000 bpd. - limited Alaska Crude.
E. MOBIL - Ferndale - 75,000 pbd. - 70% Alaska Crude.
F. SOUND REFINING - 12,000 bpd. Alaska Crude.

TOTAL Alaska Crude Refined in Washington - roughly 215,000 bpd.

The two (2) long range goals for the Northern tier project are to establish a reliable source of crude oil to northern tier states for next twenty years and to provide an improved system for transporting Alaska Crude East of Rocky Mountains.

ALTERNATIVES

1. No action or Delay Action.
2. Alternative Ports in Washington.
3. Alternative segments or routes for this system.
4. Totally different companies and routes.
5. Additional shipping to existing refineries or pipelines.

ANALYSIS

① 1. No Action or Delayed Action

As stated earlier, a 500-600,000 gallon "glut" already exists on the west coast. This substantially influences the growth of the Valdez section of the Alyeska Pipeline as they are unable to complete expansion potential.

2. Alternate Ports in Washington

The City of Valdez feels Washington Ports are a logical choice as a terminal site for Alaskan Crude. This assures shorter trips, faster turn around, maximum utilization of tankers and prevents additional ships being needed to transport further distances.

3. Alternative Segments

We have no comments...this section merely discusses alternatives to meet environmental or legal requirements.

② 4. Different Companies and Routes

The City of Valdez is quite concerned over the various alternates discussed.

(A) Alaska-Alberta (foothills) - this alternative proposes to take oil out of the existing pipeline at Delta Junction through Canada to various other refineries and pipelines in the northern Mid-West. Valdez is

Jerry Madden, State-Federal Coordinator
March 13, 1979
Page 3

concerned as this could potentially affect our community through loss in volume on the original pipeline. Valdez has been chosen as the site for the ALPETCO refinery processing 150,000 bpd of State of Alaska Royalty Oil. We are therefore very concerned over continued maximum flow through the existing line. Additionally, with all the delay and concerns expressed over the existing pipeline, what environmental effects will be generated by the foothills proposal? How does this proposal impact the D-2 lands or the Antiquities Act withdrawls by President Carter? Have the Canadian Lands Claims issue been resolved or will this be another delay factor?

③ (B) Kitimat Proposal - the second Canddian route, On both of the Canadian routes, the following questions are asked: If it is the major cutback in Canadian imports of oil creating the need for a pipeline, is it wise to consider Canadian routes?

(C) Trans-Mountain Pipeline Reversal - withdrawn at present. The biggest problem appears to be insufficient volume compared to other routes anyway.

(D) Long Beach - Midland Texas - while having the volume, this line involves longer ocean runs for the tankers and delivers oil far from the Northern market. This does not appear to actually provide the supply to the Source.

(E) Trans-Mexico - too many unkowns and again involves U.S. dependance on foreign route.

(F) Trans-Guatemala - some comments - also stated that Trans-Alaskan agreement requires U.S. control of transportation of American Oil. Does not the same apply for the other routes?

(G) Cape Horn - no specific proposal as yet but the longer ocean run stated would require larger tankers or more loading-unloading. Appears that Gulf Port destination still does not reach market area very easily.

④ (H) Transhipment-Panama - Foreign problems again. What of the new Panama Canal treaty? Is this a feasible alternative?

Jerry Madden State-Federal Coordinator
March 13, 1979
Page 4

⑤ Most all alternatives still have one basic problem! Are the Norther tier state refineries able to handle the "sour" crude? The pipeline should lead to those refineries and market areas for the end product. Additional routing, out of the way transshipments only add to the final costs.

In summary, the City of Valdez would probably favor the Northern route. Actual port location and environmental safeguards should be reviewed by the affected areas or States and it would be improper for us to suggest which of the WN. alternatives is selected. We do feel that the existing refineries and port areas should be reviewed. Additions to existing facilities, with known environmental risks, in a way, minimizes impacts by clustering, rather than starting all over with another area and spreading costs and risks over larger segments of the coastline.

Sincerely,

Mark Lewis

PORT ANGELES, WASHINGTON

March 25, 1979

Bureau of Land Management
Northern Tier Project
Room 1250
Lloyd Building
700 N.E. Multnomah
Portland, Oregon 97232

Gentlemen:

Long ago the Port Angeles Central Labor Council took a stand against the Northern Tier Pipeline proposal.

Our original opposition was based on the fear that the Northern Tier project would have an adverse effect on our quality environment. Also, we were worried that approval of the Northern Tier project might force the closure of one or more of our mills and even limit activity in our harbor.

In spite of the fact that Northern Tier has had a Citizens' Information Office operating for more than a year, our original concerns have been intensified rather than diminished.

It is also striking that there exists in Port Angeles—and, we believe, in all of Clallam County—a consensus against the Northern Tier proposal. Public officials and organizations who often disagree on development issues are united against the Northern Tier proposal. Like the Port Angeles Central Labor Council, these public officials and organizations feel that their concerns about the environment and about our economic base have not been answered adequately.

We hope that the Bureau of Land Management will consider these legitimate local concerns.

Sincerely,

Richard E. Fisch

To whom it may concern:

I urgently request a more complete EIS that addresses lands and waters which will be impacted on the new projected pipeline route, announced on March 23, 1979. The present EIS considers the lands and waters of other areas affected by earlier pipeline routes. Specifically, Whidbey Island and Camano Island are addressed briefly in the resource maps. The economic, environmental and social impacts will be extensive on these areas and must be addressed.

❶ Few people in this area know of or have seen the present EIS and are just now aware of the recently disclosed plans for the pipeline. I request an extension of the comment deadline date, April 2, until the EIS has been reviewed by the public here and public hearings have been scheduled.

❷ I have briefly reviewed the EIS for two days only and find very little in it pertaining to Whidbey Island lands, Seismic evaluation, water usage while the pipeline is in construction (water quantity is a serious problem here), the danger to the ground water supply in the event of oil leakage, the wildlife areas near the pipeline, parks in the vicinity and the fact that our aquifers underground provide most of the fresh water supply are questions which must be addressed in the EIS.

Thank you for your prompt consideration of this matter and the people it affects.

Sincerely,
Joan Tellini

Mar 25-79
Haines, Alaska
17 miles south of
Skagway on Lynn Canal!

Dear Sir:

After reading all the pro's + Con's about the pipe line Foothills plans from Skagway to Red Rivers would like to make a few comments.

Have lived here all my life. My husband was employed at the Army tank farm here in Haines in Lutak harbor.

For nineteen years one hundred thousand barrel navy tankers docked in Lutak + pumped oil into tanks to pump to Fairbanks. During this nineteen years there was never a spill, + at times there were two tankers waiting to dock in a small harbor.

The fishermen who only fish three months out of the year + then only two days a week are not supposed to be in the shipping lanes.

Am all for this pipeline even though I live in Haines.

If the U.S. + our neighbors are ever going to be independent of the black mailers all Co over seas then it is time we started.

Sincerely,
Josephine Jurgeleit
Box 44
Haines Alaska

March 26, 1979

Bureau of Land Management
Room 1250
Lloyd Building
Portland, Oregon

Dear Sirs:

Northern Tier Pipeline has recently announced plans to route their project through an alternative route, submerged under Puget Sound, and overland on Whidbey and Camano Islands.

❶ Since this proposal is a major change and very little study was given to the environmental impacts with this alternate route, we are requesting a new environmental impact statement be drafted, dealing with the impact such a proposal would have going through these very sensitive lands and the rich environment of Puget Sound waters.

❷ Island County's water resources are mainly limited to ground water supplies. Possible contamination of these sources should also be investigated.

❸ The present EIS is unsatisfactory and inadequate with the change of the route through the sound and over the islands of Island County.

Sincerely,
Harriett K Hayes

24 March 1979

Bureau of Land Management
Oregon State Director
Northern Tier Project
Room 1250, Lloyd Building
700 N. E. Multnomah
Portland, Oregon 97232

Dear Sirs: Comments, NTPC DES

❶ You gave extensive instructions to your air quality contractor on coverage of climate. However, under Paragraph 3.1 on impacts of the project there is only one sentence. "The proposed project will have no significant impact on climate." This is an unsupported conclusion. There is not even a description of the Olympic rain shadow area in the eastern part of the county. The rainfall in the Sequim-Dungeness communities is 15 to 17 inches per year, not the 24 inches to 30 inches reported for Port Angeles. The moderate temperature and relatively dry and sunny skies are extremely valuable assets to the eastern part of Clallam County. These same rain shadow effects extend into portions of Jefferson, San Juan, and Island counties. See Attachment 1. An increase in rainfall in this region would be detrimental to health, life style and property values.

We have all heard of cloud seeding to intentionally increase rainfall. Seeding can also occur inadvertantly from air pollutants. Such increases in rain and fog are well documented as taking place several miles downwind from major sources of air pollution. If the rain shadow area is seeded with the hundreds of tons of air pollutants from an oil port there will be an increase in rain and fog. It may be acid rain and damaging to plant and animal life. Visibility of snow covered mountains and sea scapes would be reduced. Severity of respiratory ailments would increase.

This county has had little experience with air pollution compared with Los Angeles-Long Beach. Therefore, it is most disconcerting to read that an oil port smaller than the one planned for Port Angeles would increase air pollution over the entire Los Angeles Air Quality Region. A comparison of the size of this region with the Olympic Peninsula is provided in Attachment 2. If the port in Long Beach will affect such a large area, as claimed by the State of California, what will a larger port at Port Angeles do to the much smaller rain shadow area? This question should be fully answered in your Final Environmental Impact Statement.

The Draft Environmental Statement is sketchy in its discussion of crude oil chemistry. The failure to use realistic vapor pressures in computations of hydrocarbon emissions invalidates all sections of the DES where hydrocarbons or photochemical oxidants are discussed. Northern Tier has apparently directed that a Reid Vapor Pressure of 2.9 psia be used for North Slope Crude. By use of weighted averages for Reid Vapor Pressures some of the estimates for HC are only one fifth what they should be, for worst case situations. Three different air quality consultants on the Long Beach impact statement used 9.5 psia for True Vapor Pressure. Several references show typical Reid Vapor Pressures as 8 to 12 psia. See Attachment 3. Since many types of crude oil will be received by an oil port some of it should have typical vapor pressures. It is conceivable that crude oil with True Vapor Pressure of more than 11.1 psia will be handled several times a year. If so, the new tank farm must be constructed with vapor recovery systems. It is requested that vapor recovery systems be provided as a mitigating measure if the oil port is approved.

❷ Your contractor, Oceanographic Institute of Washington, claimed to have difficulty in getting information on the blast effects from chemical explosives such as TNT, natural gas, or vapors in oil tankers. They then used information from a nuclear weapons effects manual and scaled the results downward to predict blast damage from an oil tanker explosion. They computed that for the worst case with a 300,000 dwt tanker the vapors detonated would be equivalent to 625 tons of TNT. For this worst case it was claimed that moderate blast damage would take place within a 2250 foot radius and no damage to the City of Port Angeles from a Blast in the harbor was indicated. Information on blast effects from actual tanker explosions is readily available in U. S. Coast Guard reports of accidents. The Coast Guard reported property damage five miles away due to the Sensienna tanker explosion in Long Beach harbor. The Los Angeles Times reported glass breakage in Costa Mesa, 21 miles from the Long Beach explosion. One of the best pieces of work done on blast effects of chemical explosives was by Dr. Mel Cook, Univ. of Utah, for Dept of Army on Contract No. Da-04-495-ORD 907 in 1957. The test detonations were made at Umatilla Ordnance Depot, Umatilla, Oregon. Data gathered for the report show windows broken at the extreme range of 6,000 feet with only 12,000 pounds of explosive. Another reference, Attachment 4, Shows glass breakage at over 100,000 feet with only 50 tons of TNT equivalent explosives. The wide variation in ranges for blast damage is due to terrain and temperature inversions, primarily. There are frequent inversons over Port Angeles and with the city located on the upslope of the mountain, a tanker explosion in the Port Angeles harbor would be a real disaster. To locate a port in Port Angeles to handle explosive cargo without first conducting small scale test detonations to study the blast wave intensification from the terrain and temperature inversions would be unwise. Such tests should be considered as a mitigating action.

❸ Your DES seems to say that the crude oil received will be free of hydrogen sulfide and that there should be no concern as to odor or toxicity. Several sources show crude oils with 2% to 5% hydrogen sulfide. A more detailed coverage of this subject is needed.

❹ Information on oil spill trajectories from NOAA Report ERL 399-PMEL29, June 1978, "Circulation in The Strait of Juan de Fuca" should be include in the final draft of your statement. Also, obtain still unpublished results on drift cards in the 9600 series released in Port Angeles harbor. It is understood that these cards were found from Green Point to Dungeness Spit and then on Whidbey Island as far south as Pt. Casey. This drift may help to answer the question whether there is really an additional oil spill safety factor for the San Juan Islands and Whidbey Island by locating an oil port at Port Angeles rather than Burrow's Bay. Such a comparison should be part of the discussion of Alternate Sites. This comparison is even more essential now that Northern Tier proposes to take their pipeline under the Sound.

❺ There is not full disclosure of the pollution possibilities with oil contaminated water at the tank farm. It appears that over 1,000,000 gallons of water previously exposed to oil would be released to Siebert Creek on certain days. In lieu of oil separators and release to the creek it is proposed that the contaminated water be collected in a separate tank and returned to the harbor through a separate pipe line and used as ballast water.

❻ Purging of cargo tanks should either be treated as a worst case hydrocarbon emission or covered more fully in the DES. Describe the emergency conditions under which purging would be performed in the harbor. Purging 10 or 20 miles from the harbor is not acceptable. Purging should be performed at least 36 hours pollutant travel time from the Puget Sound non-attainment area for photochemical oxidants.

❼ Proposals to control sulfur dioxide emissions by burning low sulfur fuel are not acceptable unless provision is made for in stack monitoring of emissions and inspections by Coast Guard to verify use of the low sulfur fuel. An alternative mitigating measure would be to provide bonnets over the tanker stacks and treat all air pollutants to acceptable levels.

❽ By August 1979 there should be Prevention of Significant Deterioration standards for nitrogen oxides as well as for sulfur dioxides and particulates. There is very little information in the DES on nitrogen oxides. Use Draft "Air Quality Criteria for Oxides of Nitrogen, November 1978" and comment on Northern Tier's ability to control ship emissions as necessary to avoid effects on visibility, animals, vegetation, human sensory systems, human pulmonary systems and acute respiratory illnesses.

❾ Now that Northern Tier has committed themselves to a pipe line under water to Whidbey Island your new DES must reveal fully the impacts of a 1,283,000 bpd throughput of crude oil on the Olympic Peninsula. There is very little impact information for this quantity of crude in the current DES. Environmentalists in the greater Seattle area continue to insist that Washington State refineries be supplied crude oil by pipe line from Port Angeles. You should no longer present mutually exclusive stories in the same statement, both favorable to Northern Tier Pipeline Co. If you continue to let Seattle residents think tanker traffic to the refineries will be reduced by a pipeline you must start telling the environmental facts to the Olympic Peninsula residents about a 1,283,000 bpd crude oil terminal.

❿ A full and conspicuously placed treatment of the alternative of an oil trade with Japan is needed. Include this subject in your Summary. The Olympic Peninsula and its adjacent waters are too valuable a resource to risk damage because of a midwest vs. west coast political squabble. Include the economic and employment advantages of preserving the Strait and the remaining clean portions of the Sound for aquaculture.

⓫ Routing the pipeline under water to Whidbey Island and the above listed deficiencies and omissions will be most difficult to cover without extensive rewrite of the DES. It is recommended that a new DES be prepared and circulated for comment.

Sincerely,
Homer V Frazier
Homer V. Frazier

PORT ANGELES LOCAL NO. 155
ASSOCIATION OF WESTERN PULP AND PAPER WORKERS
P. O. Box 2066
PORT ANGELES, WASHINGTON 98362

March 27, 1979

Bureau of Land Management
Northern Tier Project
Room 1250, Lloyd Bldg.
700 N. E. Multnomah
Portland, Or. 97232

Gentlemen:

Local 155 of the Association of Western Pulp and Paper Workers would like to go on record in opposition to preferred status offered Northern Tier.

❶ The two items we most strenuously object to are:
1) The preferential status in regards to power, and;
2) The amount of air pollution generated by N. Tier which will limit the expansion of existing industries already in the area.

Local 155 represents the workers in both I.T.T. Rayonier and Crown Zellerbach in Port Angeles. Both of these mills have been in operation for many years. Local 155 members have a vital interest in this matter, and we feel that for another industry to locate in this area and be given preferential status over existing industries is completely unfair.

Thanks for your consideration.

Sincerely,
William D. Ensor
William D. Ensor,
Pres., Local 155, AWPPW

**76**

STATE OF WASHINGTON
Dixy Lee Ray
Governor

WASHINGTON STATE PARKS AND RECREATION COMMISSION
7150 Cleanwater Lane, Olympia, Washington 98504

March 26, 1979

35-2650-1820
Draft EIS - Crude Oil
Transportation System
(E-1492)

Oregon State, Director
Bureau of Land Management
Northern Tier Project
Room 1250, Lloyd Building
700 N.E. Multnomah
Portland, Oregon 97232

Dear Sir:

The staff of the Washington State Parks and Recreation Commission has reviewed the draft Environmental Impact Statement for the Northern Tier Pipeline and offers the following comments. General comments pertaining to the impacts of the pipeline on lands under State Park jurisdiction will be presented first. Comments addressing specific points in the draft EIS will follow.

① Potentially, 12 State Parks may be impacted by the proposed Northern Tier Pipeline and associated facilities. These parks are:

Dungeness Spit
Sequim Bay
Dosewallips
Pleasant Harbor
Scenic Beach
Lilliwaup Tidelands
Potlatch
Millersylvania
Flaming Geyser (including 5 other sites in the Green River Gorge Conservation Area)
Nolte
Ollalie (including Twin Falls Natural Area)
Lake Easton

Dosewallips, Millersylvania, the Jellum and Palmer sites in the Green River Gorge Conservation Area, Nolte, Ollalie and Lake Easton are within a mile of the pipeline (within the two mile corridor). All other parks are outside this corridor, but are downstream from a point where the pipeline will cross a stream or river, or are downhill from the pipeline route.

② Impacts on most of these parks will occur during all three phases of the pipeline: construction, operation and abandonment. Visual impacts will occur where the pipeline can be seen from State Parks property. Parks that would be visually impacted are Sequim, the Jellum and Palmer Sites on the Green River, Nolte, Ollalie and Lake Easton. Excessive noise during the construction and abandonment phase would impact these same parks except Sequim.

③ In the event of a tanker spill or pipeline rupture all parks except Millersylvania could be severely impacted; part of the parks' natural amenities may be destroyed or no longer available for public use for quite some time. Sequim Bay State Park's surface water supply system may be rendered useless in the event of a pipeline rupture upstream.

Erosion during construction and abandonment phases may have significant impact on the parks using a stream, river or marine shore as part of its recreational resource.

The following comments will address the contents of the draft EIS:

④ Page 1-11 Tanker Unloading Facilities. A floating boom will be placed around each tanker after docking and before unloading. How much area will the floating boom cordon off? Without knowing the area involved, the degree of interference with recreational boaters and shore-based recreationists cannot be determined. This needs thorough evaluation in the final EIS.

⑤ Page 1-22 Table 1.4-8. Clallam, Jefferson, Mason, Thurston and Pierce counties have been omitted from the minor stream crossings list.

⑥ Page 2-31 Figure 2.1.1.12-1. If this figure represents current land use rather than current zoning, it should designate parts of the shoreline on the upland side of Dungeness Spit for recreational use. This is the site of Dungeness State Park. Also, several other recreational areas are not identified: Striped Peak, the viewpoint on Freshwater Bay, the city parks in Port Angeles, the Olympic National Park Visitor Center and that portion of the Park within the 10-mile radius of the tanker berths.

⑦ Page 2-37 Recreational Resources - Pacific Coast. Although road access to parts of the coast is limited, it receives significant use from late spring to early fall and winter use is increasing rapidly.

⑧ Camping is a significant recreational activity in North Puget Sound, parts of the Strait of Juan de Fuca and much of the Pacific Coast yet it is not mentioned in this section.

⑨ Page 2-46 Social and Economic Conditions. Millions of visitors come to the Olympic Peninsula each year, not "thousands" as is stated in the draft EIS.

⑩ Page 2-57 Aquatic Resources. The criteria for determining what is a "major" stream crossing should include each stream's recreation and natural resource values. Using physical criteria for determining what is "major" is inadequate and can be misleading as to the total value of each stream or river as a resource.

⑪ Page 3-17 In-Transit, At-Berth and Tank Farm Oil Spill Risk. It is stated that "the estimates (spill frequency) are valid only if conditions do not change significantly from historical patterns." Historical patterns for the physical conditions (weather, currents, tides, etc.) in the Strait of Juan de Fuca exist. However, the historical patterns for large tanker traffic in the Strait do not exist because very few tankers of the size proposed have ever entered the Strait. How can spill frequency for in-transit tankers traffic be generated if this data does not exist? If the in-transit data comes from other sites how can it be valid for the Strait of Juan de Fuca?

The data presented for spill frequency and predicted spill pathways is for an undertermined amount. What is the worst possible case?

What will be the long-term effects of small, frequent spills?

⑫ Page 3-37 Visual Resources. Hurricane Ridge and the road leading to it offer spectacular views to the north. Ediz Hook and Green Point are clearly visible from major viewpoints. The tanker berths and facilities and the tank farm will definitely intrude upon these views.

**CONT.**

⑬ Page 3-47 Recreation Resources. It is stated that "curtailment of use of the Port Angeles-Victoria auto ferry would affect an indeterminate number of recreationists..." How and when will ferry operations be curtailed? What would be the loss to ferry users and the Washington State Department of Transportation in terms of convenience, availability of transportation, revenues, etc?

In evaluating the impacts of tanker accidents and pipeline ruptures on recreation, economic data showing the dollar value of potentially impacted recreation facilities and activities needs to be presented. Recreation is a significant part of the state's economy. Residents of Washington and both out-of-state and foreign tourists pursuing recreational activities support some of the larger industries in the state. Activities such as recreational boating, shellfish harvesting and sports fishing provide some of the largest economic benefits to the state.

Data reflecting these economic benefits must be presented. Use data for established recreational sites and facilities is also essential in assessing the impacts of the pipeline.

⑭ Page 3-48 A tanker spill off of Neah Bay may adversely affect the Olympic National Park Wilderness Beaches along the Pacific Coast.

⑮ Page 3-50 Social and Economic Conditions. The assumption that "damages from an oil spill to aesthetic and recreational values would have a minor effect on tourism" is false. Effects may be minor to severe. The effects of a massive oil spill on the motel business of the city of Santa Barbara cannot illustrate the total impacts of an oil spill of the same magnitude in the Strait of Juan de Fuca or in Port Angeles Harbor.

⑯ Page 5-10 Unavoidable Impacts. A marina and a boat launch facility in Port Angeles Harbor will be lost to recreational boaters. The disruption of the harbor and boating traffic caused by the Northern Tier port facility will impact water-related recreational activities. Construction, operation and abandonment of the pipeline and related facilities will have minor to severe impacts on recreation. Some impacts will be short-term, others long-term. Oil leaks and spills will possibly be detrimental to recreation. All the disruptions or damage to recreation activities and resources will cause an economic loss to the State of Washington and its citizens which may be long-term and of a significant magnitude.

⑰ Page 6-2 Onshore Storage Facilities. "The notch may also change erosion rates on the cliff, and thereby affect the deposition of silts and sands on Dungeness Spit east of Green Point." Anything that may change the erosion rates of the bluffs west of Dungeness Spit will alter the accretion rates of the spit. If breaching of the spit occurs more frequently due to erosion control measures at the bluffs, severe damage may occur to the spit and its resources. This is particularly true in the event of an oil spill when the spit has been breached. This must be considered as a very severe potential adverse impact upon recreation and the natural resources of the area.

Page 8-37 Low Point-Preferred Alternative. This alternative port site will have fewer impacts on recreation than the Port Angeles site. Marine facilities, harbor and ferry traffic would not be disrupted as is the case with Port Angeles port site although tanker traffic and the offshore single point mooring systems will interfere with recreational and some commercial boating traffic.

⑱ Tanker accidents on route to or docking at Low Point will have much the same impact as accidents occurring on route to or in Port Angeles Harbor including possible damage to Dungeness Spit (see comment under "Page 6-2 Onshore Storage Facilities"). Pipeline leaks and spills will affect an additional 24 rivers and streams, many which have high recreation and natural resource value. Pipeline spills at stream and river crossings will also impact the shoreline along the Strait of Juan de Fuca.

⑲ Page 8-43 Recreation Resources. In the event of a spill at Low Point many recreational activities and facilities in the Strait of Juan de Fuca, the San Juan Islands and Canada may be severely impacted. These impacts may be short or long-term. Once again, economic data showing the dollar value of potentially impacted recreational facilities and activities needs to be presented to fully evaluate the impacts.

Erosion and bottom sediment disruption during the construction and abandonment phases of the port facilities and pipeline may have significant impact on areas with high recreation and natural resource value.

⑳ Page 8-49 to 57 Cross Puget Sound Alternative. Potentially 13 parks will be impacted by this proposed alternative pipeline route. These parks are:

Dungeness Spit
Sequim Bay
Fort Worden
Old Fort Townsend
Fort Flagler (including Mystery Bay Recreation Area)
Fort Ebey
Fort Casey
Joseph Whidbey (Whidbey Island NAS)
Deception Pass
South Whidbey
Camano Island
Ollalie (including Twin Falls Natural Area)
Lake Easton

Fort Ebey, Joseph Whidbey, Ollalie and Lake Easton are within 1 mile of the pipeline. The pipeline passes through the proposed development at Joseph Whidbey State Park. All other parks are along shorelines that may be impacted during the construction, operation and abandonment phases depending on the currents, tides, wind and weather.

In the event of a pipeline leak or rupture all these parks may be severely impacted. (In addition to these parks, the Washington State Parks and Recreation Commission owns and operates a dozen marine parks and miscellaneous small islands in the San Juan Islands. Any of these may also be impacted by a pipeline rupture.) The visual impact would be great under these circumstances. Many recreational activities would be lost for a short or long duration. Natural amenities of each of these parks may be lost (shellfish and fish resources, etc.). Some facilities may be damaged. Bottom sediment disruption or land erosion during construction and abandonment phases may have significant impact on the shoreline or water related activities of each of these parks.

㉑ Page 8-51 Marine Resources. A leak detection system capable of sensing a 0.5 percent loss of throughput volume is highly inadequate. This means over 148,000 gallons per day during the initial throughput or over 195,000 gallons per day during the final throughput may go undetected until sighted. There are many times in the Northern Sound and the Strait when the weather conditions could prevent the oil from being sighted immediately.

㉒ Page 8-56 Recreation Resources. There are two state parks proposed for development in the pipeline corridor: Fort Ebey and Joseph Whidbey. (see comment under "Page 8-49 Cross Puget Sound Alternative")

A more in-depth analyses of impact of this proposed pipeline on recreation activities and resources is needed. Economic data needs to be presented.

㉓ Page 8-60 Stampede Pass Route Alternative. Lake Easton State Park would still be affected by the pipeline and the impacts are the same as those stated for the original proposal.

㉓ Page 8-61 Naches Pass Route Alternative. Federation Forest State Park will be impacted by this alternative route segment. The park is within one mile of the pipeline and is downstream from the crossings of the White and Greenwater Rivers. Impacts may be visual and aesthetic. Water quality of the rivers may be degraded. Oil spills may impact recreation.

In summary, all phases of the Northern Tier Pipeline and associated facilities may adversely impact recreation activities, specific facilities, and the natural resources that enhance recreation. The impacts may be short term, long term or permanent. The draft environmental impact statement does not provide adequate information to determine the full impact of the pipeline on recreation resources in the State of Washington. More detailed and additional information is needed in order to fully assess the impacts.

Thank you for the opportunity to review and comment on the Northern Tier proposal.

Sincerely,

David W Heiser

BARBARA D. KALEN
Box 317
Skagway, Alaska 99840

[illegible] 1979

Bureau of Land Management
Oregon State Office
729 N. E. Oregon St.
Portland, Or. 97232

Dear Sirs:

① I wish to confirm, and add to my oral testimony concerning the [illegible] proposal for a tanker port at Skagway, and an oil pipeline over the White Pass, following the [illegible] right-of-way. I feel that the strongest argument against this is the danger to fisheries in Southeast Alaska from possible oil spills. Fishing is a multi-million dollar business in Southeast Alaska, supporting many fishermen, their families, and businesses in nearly every town.

All of our waters from Chatham Straits north to Lynn Canal would be endangered—it would be very possible that a single spill could wipe out large portions of the salmon runs if they happened at a time when spawners or fingerlings were in the affected area—the same could happen to the herring, which are the foundation of the food chain, and food for many other larger species. It would not matter that in a few years the waters and beaches would recover—a run destroyed is gone.

Just look at the rest of the world and ask what pollution by man has done to the Atlantic salmon runs in Europe, on the East Coast of north America, the salmon that used to run in California rivers, the rapidly diminishing runs in the Columbia river and Puget Sound?

Throughout the world man is losing resources by overfishing and pollution—both effective ways to destroy the fish. A crisis in nearly all of the third world is the simple matter of firewood. Villagers are [illegible] miles and miles, cutting every tree and bush, so that there will be nothing available for their children in a few short years time. The same thing happens with grazing land, and water tables, where ground water that has taken centuries to accumulate is being lowered for irrigation, and often (and often, in the U. S. at least, for luxury uses). Thousands of acres of land throughout the world are turned to desert each year by man's short-sighted overuse for the present, and I feel that this global problem must be solved by a much stronger search for alternate energy sources, and a real turnaround to truly effective use of technology and a halt of the present business practices of planned obsolescence. This line of thinking is very relevant to the whole question of whether this pipeline needs to be built at this place at this time, and I hope you will give it some consideration.

To get back to our local problems, assuming that the Federal Government does decide to push for this line anyway: the Northern Tier proposal outlined in the booklet given out at the Skagway meeting Feb. 20 estimates that 112 acres of the harbor in the Port Angeles area would be impacted. Skagway does not have this much harbor for all of the uses presently accommodated—general cargo, bulk ore, tour ships, ferries, small boat harbor, and barge traffic. That is going to get squeezed out by the addition of a large tanker nearly every day. Tour ships, for example, contribute a great deal to Skagway's economy. Total tourist contribution to Skagway, in the form of rail tours, hotel lodging, sightseeing, restaurants, souvenirs, summer jobs to accommodate these people, can be estimated at from 1/3 to 1/2 of Skagway's total economy.

Again, the Northern Tier proposal calls for a 90 foot wide construction corridor, and a 75 foot permanent right of way corridor. There are several places on the White Pass where this is literally impossible. Most of the slope is [illegible] so steep, that they are naturally unstable,

continually eroding, and building talus slopes. Any disturbance, and a trench large enough for a 24" pipeline is surely going to be a disturbance, makes the land that much more unstable. The WP&YR has experienced both rock and snow [illegible] every year since it was built. It is relatively easy to repair rail and ties, and to recover locomotives and other rolling stock fallen off the right-of-way is not [illegible] to the land and water as a broken large oil line and spill could be. Mention has been made of the negligible damage from the 4" pipeline north from Skagway, and the 8" line north from Haines, both of which have suffered breaks, the Skagway one many more than the Haines, due to our terrain. I think the difference in capacity between these little lines and a 24" one makes such a comparison of little value. In our narrow canyon, with porous sand and gravel overlaying bedrock, a spill would rapidly percolate into the water table, and could make Skagway's water supply unusable for many years.

A construction camp nearby could create short-term problems for water and sewer, garbage disposal, police and school needs, which could prove a greater expense to the city than the extra money the workers would spend. All previous experience of construction workers in Skagway, elsewhere in Alaska, and probably all over the world is that the bulk of their wages gets blown on liquor and gambling, and does not benefit the total economy very much. Those workers who do not blow their money will save it, and spend it when they get back to their stateside homes.

Which brings up the subject of who will get these jobs, anyway? How many Alaskans will be hired, or trained, for the jobs? The Alyeska experience suggests "not very many." We also find ourselves wondering about the total number of real jobs operating the facility after it is built. 60 sounds like an inflated figure for an automated operation. We've heard some local citizens crying about the small present prospect of jobs for our high school graduates, but this is a fact that has been with Skagway ever since the town was founded. Kids who get an education, especially if they go on to college, have never found satisfying job opportunities in Skagway. How many of these pipeline jobs would go to local H. S. grads? Would they not go instead to highly trained, experienced personnel from some place else, or will our local people be given a chance to be trained?

Has any serious consideration been given to using the port, tank farm, and right-of-way at Haines? We still feel that tanker traffic in S. E. waters is highly undesirable, but if national policy dictates a pipeline in this area, it seems to some of us that there is better and larger berthing room at Haines, plus a great deal more flat land for everything, and a much less hazardous right of way for the pipeline, following the existing pipeline from Haines to the Alaska Highway.

Real estate assessments in Skagway have gone up 700 to 800% in the past ten years, and cost of business has risen [illegible]. Experience here during W. W. II and during the Alcan boom indicates that any further pressure would raise prices still more—and outside speculators would force prices right out of sight. Especially as Skagway does not have enough land to support very much reasonable expansion—much of what is vacant is held by owners who refuse to sell at any price.

Yours very truly,

Barbara D. Kalen

ISLAND COUNTY
Historical Society
Formed in the interest of preserving the history of Island County
P.O. Box 305
Coupeville, Washington 98239

March 28, 1979

Bureau of Land Management
Room 1250 Lloyd Building
Portland, Oregon 97232

Gentlemen:

① Regarding the Northern Tier Pipeline Company's proposal for an oil port and oil pipeline in Washington state: We feel the EIS of this proposal should be rewritten and resubmitted to reflect the major route change announced by Northern Tier March 23, 1979.

This route change may have a drastic adverse impact on the historical character of Whidbey and Camano Islands and their surrounding waters, which are under the auspices of the Island County Historical Society. This area is of great national importance historically and has been recognized as such many times by the Federal Government.

We have had no opportunity to study and assess this proposal regarding how it would affect Island County's historic and aesthetic character.

We request public hearings on this proposal. We also desire to be included in all hearings, meetings, documents, mailing lists, etc. concerning this proposal.

Thank you.

Sincerely,

ISLAND COUNTY HISTORICAL SOCIETY

Joan McPherson

RE: Environmental Impact Statement
Northern Tier Pipeline Crossing
Whidbey and Camano Islands

Gentlemen:

It has come to our attention that the Environmental Impact Statement for the Proposed Northern Tier Pipeline does not give adequate attention to its impact on the Puget Sound Crossing and its impact on Camano Island.

As residents and homeowners on a unique scenic/residential/agricultural/forestland Island, we must be fully apprised of the pipeline's impact.

Our concerns include:

① 1. The effect of construction on our tidelands. What will happen to our natural tidal channels which were disrupted by the previously installed gas pipeline?

2. The effect of an underwater rupture due to earthquake or accident, particularly in view of the fact that no automatic shut-off controls are planned where the pipeline enters or leaves the water.

3. The effect of a 75 ft. wide right of way on the adjacent property values and the environmental and scenic values on Camano Island. This is extremely important since no structures or plantings would be planned nor permitted.

4. The effect of a pipeline rupture on our water aquifers where they will be intercepted by the pipeline.

② We feel that our rights and concerns are being ignored, and respectfully request that steps be taken to make certain that an E.I.S. specifically addressing the concerns of Camano and Whidbey Islands be required.

Sincerely,
Wm. P. Dunlop

LINCOLN COUNTY

Review of Draft Environmental Statement
by the Bureau of Land Management
on the Proposed Northern Tier Pipeline Project

In our study of the Bureau of Land Management Environmental Statement, several strong points were revealed. These points are helpful to us in accessing Lincoln County's concerns in view of the proposed construction of the Northern Tier Pipeline.

The existance of a waterfowl nesting area the the upper end of Sprague Lake is shown in the B. L. M. document to be significant.[1] Knowledge of this will help to access possible damage due to an oil spill in Sprague Lake.

An area in Lincoln County, along the pipeline route, was shown to have critical water erosion potential in the B. L. M. document.[2] Significant slope instability and liquification potential exist in certain areas of Lincoln County along the proposed pipeline route according to the B. L. M. Map Addendum, pages 85-87. The B. L. M. Map Addendum soil information is easy to interpret compared to more complex soil survey data, and has helped show us the need for extreme erosion control measures in places along the Lincoln County pipeline route.

The general organization of the report material was good, in that we were able to find whatever information we needed on the various subjects we studied, among the material covered in the B. L. M. document.

In our studies of the B. L. M. Environmental Statement, several weak points were brought out.

① The report in general was not detailed enough to cover most local problems adequately. For example, a map showing the probability of an oil spill mile by mile along the proposed pipeline route would have been helpful, along with the provided topographic information, in accessing whether proposed placement of mainline valves is adequate to protect county needs.

The environmental and soil characteristics maps were, in some cases, not detailed enough to cover the entire 2 mile wide pipeline corridor.

1. B. L. M. MAP Addendum, p. 86 & 87
   B. L. M. Environmental Statement, p. 2-100
2. B. L. M. Map Addendum, p. 84-87
   B. L. M. Environmental Statement, p. 3-63

② Some research done in the B. L. M. document was incomplete. For example, extensive study was done on the types of crops that would be most affected by an oil spill into a canal system. The amount of time required for soil recovery and methods of conditioning soil to speed recovery were discussed.[1] Nothing was discussed, however, on the number of acres of land which would be affected.

③ In some cases, our study of the B. L. M. document raised questions. Conflicts of data were found in comparing the B. L. M. document with other sources of information. One example of this is the claimed existance of the 36" Pacific Transmission Company natural gas pipeline in Lincoln County; we found no information on this pipeline anywhere but in the B. L. M. Environmental Statement on page 2-134.

1. B. L. M. Environmental Statement, pages 5-21, 3-105 and 106, 1-59

ADEQUACY OF B. L. M. DOCUMENT
in COMPLEMENTING SPECIFIC PROBLEM STATEMENTS

A - 1a. PROBLEM STATEMENT: There would be a break in the irrigation schedule, which would damage cropland if the pipeline canal crossing is built during the irrigation season and the East High irrigation canals are in service (Vol. II; Application for Site Certification; p. 6-105).

A - 1b. PROBLEM STATEMENT: An oil spill into the propsed East High Canal systel would damage hundreds of thousands of acres of cropland downstream in Adams, Grant, Lincoln, and Franklin Counties (U. S. B. R. Columbia Basin Project map; Jan., 1977).

REVIEW COMMENTS: The B. L. M. Environmental Statement made mention of the fact that ground saturated with oil from an oil spill into an irrigation system could take from one to five years to recover, but that cultivation and fertilization would speed this recovery process.[1] Types of crops most susceptible to oil contamination are mentioned, as well as pipeline inconveniences to irrigated land, (leveling, canal construction, etc.) in the B. L. M. document.[2] The B. L. M. made the statement on page 3-105, in the Environmental Statement, that 3' may not be a sufficient burial depth for the pipeline in agricultural areas. It was also stated that planning and timing will be needed to lessen pipeline impact on future irrigation projects like the proposed East High project.[3]

1. B. L. M. Environmental Statement, p. 5-21, 3-106
2. B. L. M. Environmental Statement, p. 5-21, 3-106, 3-105
3. B. L. M. Environmental Statement, p. 1-59

④ B - 1a. PROBLEM STATEMENT: Some of this area is characterized by soil with a permeable gravel underlay where a small pipeline leak of 2-5 gpm would go undetected at the surface of the ground, thereby polluting the environment (Vol. II, Part II; Application for Site Certification, p. 2.11-70, and Adams County Soils Survey map, p. 8).

REVIEW COMMENTS: Soil types and characteristics are discussed in some detail in the B. L. M. Environmental Statement; permeability is also discussed to some degree.[1] No apparent discussion is made on the subject of oil permeability in soils, however, in the B.L.M. document.

⑤ B - 2a. PROBLEM STATEMENT: Open pipeline trench or construction equipment will harm or restrict range animals during pipeline construction.

REVIEW COMMENTS: The B. L. M. Environmental Statement mentions that open pipeline trench and construction equipment operation could cause livestock injuries or fatalities.[2] On page 1-44 in the B. L. M. document, it states that the pipeline trench will be open for as short a time as possible. The reviewer found nothing in the B. L. M. report about skipping sections during construction so range animal movement would not be hindered.

CONT

B - 3a. PROBLEM STATEMENT: An insufficient number of block and check valves are currently proposed for the Sprague Lake drainage area, increasing the probable volume of an oil spill in that area (Vol. IV; Application for Site Certification, p. 806170).

PROBLEM STATEMENT: Too few mainline pipeline valves have been proposed for the Northern Tier Pipeline in the Negro Creek - Sprague Lake drainage; the potential volume of oil spilled during an oil spill will therefore be excessive. (Vol. IV, Application for Site Certification, p. 806170).

1. B. L. M. Map Addendum, p. 84-87 and p. 127-128
   B. L. M. Environmental Statement, p. 2-54 to 2-55
2. B. L. M. Environmental Statement, p. 3-104

REVIEW COMMENTS: The characteristics and location of mainline valves are given in the B. L. M. Environmental Statement on pages 1-24 and 1-25.

As mentioned earlier, the reviewer would be in favor of a map or list showing areas where the probability of an oil leak or spill would be greater than the pipeline average. With this information, Lincoln County personnel could plan, with the use of topographic data, where block and check valves should be placed in Lincoln County.

⑤a Department of Transportation regulations regarding the placement of mainline valves are discussed; however, no indication of adequacy in protecting Lincoln County is given in the B. L. M. document.[1]

C - 1a. PROBLEM STATEMENT: If careful planning is not implemented, on the part of the pipeline company, traffic will be slowed on Interstate 90. (Vol. III, part II, pages 5-53) (Vol. II, Application for Site Certification, p. 6-147).

REVIEW COMMENTS: The B. L. M. document on page 2-127 states that 8,200 vehicles per day used Interstate 90 in 1976 in the area of the proposed pipeline crossing. The B. L. M. mentioned that interstate highway crossings will probably be bored or tunneled with little or no traffic disruption.[2] The reviewer believes that the pipeline will be placed under I-90 at the Lincoln County road 9220 underpass just east of the I-90 Sprague rest areas.

The B. L. M. did mention the possibility of damage to transportation or utility systems near the pipeline construction site.[3] On page 5-22, the B. L. M. document states that oil spills or oil spill cleanup activities could damage transportation or utility networks.

⑥ C - 3a. PROBLEM STATEMENT: Pipeline construction activities at the Negro Creek crossings will cause excess sedimentation downstream in Negro Creek and Sprague Lake. (Vol. III, part II, Application for Site Certification, p. 5-8).

1. B. L. M. Environmental Statement, p. 1-24 and 1-25
2. B. L. M. Environmental Statement, p. 3-108
3. B. L. M. Environmental Statement, p. 5-21

REVIEW COMMENTS: Negro Creek is not mentioned in the B. L. M. document in the water quality characteristics section on pages 2-64 to 2-69.

The physical components of runoff water from pipeline construction across streams is discussed on page 3-67. The general feeling conveyed in the B. L. M. document is that sedimentation and siltation will take place for about one month after the construction and then the streams will return to normal.[1] Damage could be caused to fish due to siltation, but probably won't be, according to the B. L. M. study on page 3-78. The B. L. M. suggests on page 4-3 of their study, that flow be diverted around pipeline-stream crossings during pipeline construction to minimize sedimentation. Timing construction activities to protect spawning fish is also mentioned, in the B. L. M. document on page 4-2, as a mitigating measure. In general, the subject of siltation during pipeline construction across watercourses is well covered by the B. L. M., however, the specific impact of construction in the Sprague Lake drainage is not mentioned.

⑦ C - 4a. PROBLEM STATEMENT: Due to the close proximity of the proposed pipeline route to the town of Sprague, dust will be a problem. (Vol II, Application for Site Certification, p. 6-100).

REVIEW COMMENTS: A wind erosion map provided by the B. L. M. on pages 86-87 of the B. L. M. Map Addendum shows a significant amount of wind erosion should not occur in the Sprague area. On page 128 of the Map Addendum, the wind erosion potential is shown as medium in the Sprague area. Watering and mulching disturbed soils are mentioned as mitigating factors on page 4-2 of the B. L. M. Environmental Statement. The pipeline company is committed to dust control measures in populated areas. The reviewer found no indication by the pipeline company or the B. L. M. of whether Sprague is considered populated enough for the implementation of dust control measures during pipeline construction.

1. B. L. M. Environmental Statement, p. 3-67, 3-72, to 3-78.

⑧ C - 4b. PROBLEM STATEMENT: The safety of children and adults near the pipeline construction right-of-way will be endangered by construction activities.

REVIEW COMMENTS: No specific statements about safety during construction, near the pipeline right-of-way, was found in the B. L. M. Environmental Statement by this review.

C - 4c. PROBLEM STATEMENT: Excessive noise will be a problem in the Sprague area due to the close proximity of Sprague to the proposed pipeline route and due to the location of the pipe stockpile site in Sprague. (Vol. III, part II, Application for Site Certification, page 5-39, 5-40). (Vol. V, Part I, Application for Site Certification, pages A-6-7 to A-7-1).

CONT

REVIEW COMMENTS: In the B. L. M. Environmental Statements on pages 2-49 and 2-50, discussions of noise receptors along the pipeline route are discussed. Sprague is included in this list of noise receptors. The distance from Sprague to the pipeline centerline is expected to be 1,000'. It is noted on page 2-49 of the B. L. M. document that Washington State has laws regarding excessive noise at night. Pipeline construction will be limited to daytime as mentioned on page 3-58 of the B.L.M. study. The table on page 3-59 states that the maximum noise level for Sprague will be 62 decibles, and 55 decibles for a length of four days. Except for the fact that a layman has no idea how loud 62 decibles is, from the B. L. M. data, noise level information is covered quite well for the Sprague area.

⑨ C - 4d. PROBLEM STATEMENT: The City of Sprague is inside of the Northern Tier Pipeline Company's two-mile wide pipeline corridor; legally, if Lincoln County accepts this corridor, the pipeline could be placed inside the City of Sprague; pipeline construction and operation inconveniences will be felt by the people of Sprague, if this happens. (Vol. IV, App. for Site Certification P.806509)

REVIEW COMMENTS: This problem is not mentioned in the B. L. M. document.

C - 5f. PROBLEM STATEMENT: This area is characterized by a high perched water table; undetected pipeline leak in this area will pollute the perched water table and transport oil through the perched aquafer, and possibly into a groundwater recharge area, polluting the deeper water table. (Vol. IV, Application for Site Certification, p. 806343-806344).

⑩ REVIEW COMMENTS: The B. L. M. Environmental Statement, on page 2-69, mentions the probable existence of a shallow perched water table between pipeline miles 340 and 435. This shallow water table, in the reviewer's opinion, does exist, especially from Sprague east in Lincoln County. According to the B. L. M. draft, on page 3-67, especially critical areas for oil spills are high water table regions and groundwater recharge areas. In review of the B. L. M. document, nothing was mentioned about where any ground water recharge areas in Lincoln County are located. Nevertheless, the B. L. M. document does warn us of the dangers of an oil spill into a shallow water table.

D - 1a. PROBLEM STATEMENT: Future County development will be hindered by placing the pipeline in an area where the pipeline would conflict with local land use decisions.

⑪ REVIEW COMMENTS: Land use and comprehensive plan studies are generally already mitigated through local land use hearings. Local shoreline management ordinances, and conformance of local proposed pipeline construction plans to local ordinances, are not covered in the B. L. M. document.[1]

D - 1b. PROBLEM STATEMENT: Crude oil is forecast to be a primary energy source for the U. S. through 1990's. If the pipeline is only to be used for a short time, losses in county goods and services will outweigh benefits (Vol. II, Application for Site Certification, p. 6-205).

REVIEW COMMENTS: Alternative proposals for crude oil transportation are described in the B. L. M. document.

⑫ Alternative energy sources, which might eliminate or lessen the need for a petroleum pipeline in future years are also apparently not mentioned in the B. L. M. study.

⑬ D - 2a. PROBLEM STATEMENT: When conflicts arise with the pipeline company, it may be uneconomical for agencies or individuals to recover damages due them because of the substantial legal resources of the pipeline company.

REVIEW COMMENTS: The use of a mediating board or other third party legal processes to resolve conflicts between counties and the pipeline company was apparently not discussed in the B. L. M. Environmental Statement. In the reviewer's opinion, the problem of legal processes is a very real concern when dealing with an agency as large as a pipeline company.

D - 2b. PROBLEM STATEMENT: The "Oil Spill Contingency Plan" has not been made public. This leaves the agencies and individuals of our county uninformed about how oil spills will be cleaned up and who will pay for their cleanup. (Vol. II; Application for Site Certification, p. 6-1-134) (Vol. III, Part II, Application for Site Certification, p. 5-31).

⑭ REVIEW COMMENTS: The B. L. M. document quite extensively discusses the Oil Spill Contingency Plan and the elements it will contain when it is released.[1] It did not say exactly when the Oil Spill Contingency Plan would be brought out, nor how much control Lincoln County would have in revising the Contingency Plan if it is not adequately protective of county property.

PROBLEM STATEMENT:
D - 3a. Some Lincoln County roads will be unable to stand the stresses of heavy equipment transportation needed in pipeline construction.

D - 3b. PROBLEM STATEMENT: If the backfill is improperly replaced on public and private road crossings, damage will occur with use by car, truck and heavy equipment. Improper construction practices could result in undue tension being placed on the pipeline, with a possibility of fracture.

D - 3c. PROBLEM STATEMENT: Future changes of grade on county roads will be more restrictive if the pipeline is placed at a minimum depth under county roads.

D - 3o. PROBLEM STATEMENT: Construction in Adams County will undoubtedly require the use of some Lincoln County access roads, especially in the 18-20 month construction period for pump station number eight. (Vol. II, Application for Site Certification, p. 6-107).

⑮ REVIEW COMMENTS: Very little was mentioned by the B. L. M. about sharing responsibility on road maintenance costs or services. The Forest Service statements on page 4-7 in the B. L. M. document mentioned the need for maintenance standards and responsibility during pipeline construction and operation.

This review located nothing in the B.L. M. Environmental Statement about the problem of future road grade changes and their restriction by pipeline placement.

1. B. L. M. Environmental Statement, [illegible]

82 CONT

⑮ An improperly rebuilt roadbed (public or private) over the pipeline could place undue tension on the pipeline. This factor was apparently not mentioned in the B. L. M. document.

The B. L. M. document did discuss road use damage or delay during pipeline construction or spill cleanup.[1]

Alternatives such as load limit restrictions, placement of shield pipes, extra pipeline depth, and improved roadbed construction were evidently not specifically dealt with in the B. L. M. statement.

D - 3d. PROBLEM STATEMENT: Land leveling or deep ripping to break up hardpan would damage the pipeline if farmers work the soil deeper than the proposed minimum pipeline depth of 36". (Vol. I, Application for Site Certification, pages 2-14).

REVIEW COMMENTS: In the B. L. M. Environmental Statement on page 3-105, it states that a burial depth of 3' will be restrictive to certain agricultural activities. Included in the list of restricted agricultural activities is land leveling, irrigation ditch construction, and border type irrigation. The document cites the proposed East High Canal System as an example of a potentially affected area.

D - 3e. PROBLEM STATEMENT: Lincoln County government and citizens will need to provide extra services such as housing, law enforcement, health, fire protection; school space and other services during pipeline construction.[2] Probable short term increases in population for cities along the pipeline route include: 16.5% for Ritzville, 7.9% for Lind, and 5.3% for Othello.[3]

G - 3f. PROBLEM STATEMENT: The major portion of pipeline construction will take place from April through November 1980; this will have an adverse effect on agricultural activities; especially on wheat harvest. (Vol. II; Application for Site Certification, p. 6-105).

1. B. L. M. Environmental Statement, p. 2-141
2. B. L. M. Environmental Statement, p. 4-8
3. B. L. M. Environmental Statement, p. 5-20

⑯ REVIEW COMMENTS: Traffic delays to adjoining land uses are mentioned as an impact of pipeline construction or spill cleanup. [1] In the reviewer's search, nothing was found in the B. L. M. document specifically about possible holdup of agricultural activities due to road blockage during pipeline construction It is very important that detours be used to keep roads open during pipeline construction activities, so that harvest will not be delayed.

D - 3g. PROBLEM STATEMENT: The pipeline company has not shown where material sites, for rock-free fill material or waste dump sites, will be located. Improper location of such sites will be unsightly and perhaps erosive. (Vol. III, part II; Application for Site Certification, p. 5-17).

REVIEW COMMENTS: The B. L. M. Environmental Statement mentions general areas of location and reclamation of borrow sites.[2]

D - 3h. PROBLEM STATEMENT: The Northern Tier Pipeline Company was not specific at what maximum pipeline slope they would begin placing erosion control devices or materials to help control erosion in the pipeline trench, should a large runoff period occur.

⑰ REVIEW COMMENTS: Detail discussion of erosion amounts per acres was given in the B. L. M. document as well as other related erosion problems. No specific discussion on placement of pipeline trench erosion control devices was found in the B. L. M. document by this review.

G - 3i. PROBLEM STATEMENT: No statements about dust control in rural areas were made by the pipeline company; dust (wind erosion) removes a large amount of farmable topsoil from the land.

REVIEW COMMENTS: A wind erosion map provided by the B. L. M. on pages 84-87 of the B. L. M. Map Addendum shows a significant amount of wind erosion could occur in parts of Lincoln County. Wind erosion in lbs./acre is covered on pages 3-63 and 3-64 of the B. L. M. Environmental Statement in Lincoln County. Watering and mulching disturbed soil are mentioned at mitigating factors on page 4-2 of the B. L. M. Environmental Statement.

1. B. L. M. Environmental Statement, p. 2-141
2. B. L. M. Environmental Statement, p. 4-2

D - 3j. PROBLEM STATEMENT: Many of the wheatland, loessial soils, through which the pipeline will pass, are subject to erosion during severe runoff periods. Gullies or slumps will expose the pipeline during times of severe erosion, especially right after construction when the fresh pipeline backfill has not yet compacted. (Vol. III, part II; Application for Site Certification, pages 5-24.

REVIEW COMMENTS: The erosive character of the loessial soils in Lincoln County is brought to our attention in the B. L. M. Map Addendum on pages 84-87. On page 4-2 of the B. L. M. Environmental Statement, a measure which would have the pipeline avoid areas of high potential for mass failure is proposed by the U. S. Forest Service. The B. L. M. document shows two areas along the pipeline route in Lincoln County where slope instability or mass failure potential will be a problem.[1] The two areas shown in the B. L. M. study where slope instability is a problem correspond to Bagdad and Anders-Benge-Rock Outcrops Association soil types. In the reviewer's opinion, pipeline construction in these soil types should avoid steep slopes.

⑱ Another soil problem which exists in Lincoln County that has not yet been brought to attention, is the low cohesive strength of the Ritzville soil types through which the pipeline will pass. According to Adams County, U. S. D. A Soil Conservation Service, Soil Survey, Engineering Interpretations, published after 1970, slope cave-in danger is critical on these soils when excavated or trenched. Since the minimum depth of the proposed Northern Tier Pipeline trench is 78", safety hazards to workers in the pipeline trench are to be expected. The Soil Conservation Service information recommends sloping the sides of trenches in these Ritzville soil types, and any soil type which lacks cohesive strength, as a safety measure to workers in the trench.

CONT

D - 3k. PROBLEM STATEMENT: The safety of children and adults near the pipeline construction right-of-way will be endangered by construction activities.

⑲ REVIEW COMMENTS: No specific statements about safety during construction, near the pipeline right-of-way, were found in the B. L. M. study, by this review.

D - 3m. PROBLEM STATEMENT: Sabotage is possible on the pipeline if it is placed above the ground at canal or stream crossings. (Vol. II; Application for Site Certification, p. 6-60).

⑲A REVIEW COMMENTS: The possibility of sabotage at an overhead pipeline-canal crossing is mentioned on page 3-106 in the B. L. M. Environmental Statement. Mitigating measures dealing with this problem were not found in the B. L. M. document, by this review.

D - 3n. PROBLEM STATEMENT: Utilities services will be cut off to local residents if the pipeline company accidently severs utility lines during excavation for pipeline construction.

REVIEW COMMENTS: The possibility of damage to utility systems is discussed in the B. L. M. Environmental Statement on page 5-21. An oil spill or oil spill cleanup may cause damage to a nearby utility or transportation system,according to the B. L. M.[1] The B. L. M. states, on page 3-107 of their Environmental Statement, that pipeline construction and pipeline electrical use might interfere with possible expansion of electrical transmission systems.

The fact that close coordination would be maintained between the pipeline company and other utility companies through crossing and joint use permits is mentioned by the B. L. M.[2]

D - 4a. PROBLEM STATEMENT: Ten minutes will be needed to shut the pipeline off and close mainline valves in case of a pipeline break,the volume of oil spilled in this period of time would be enormous, in the case of a pipeline rupture. (Vol. II; Application for Site Certification, p. 6-102).

D - 4b. PROBLEM STATEMENT: Based on data from existing oil pipeline, oil spills of an average volum of 2,747 barrels per spill can be expected once every 21 years in Lincoln County; one such spill would damage a large area of land. (Vol. I; Application for Site Certification, p. 2.11-55 and page 2.11-70).

1. B. L. M. Environmental Statement, p. 5-22 & p. 3-107
2. B. L. M. Environmental Statement, p. 5-21

D - 4c. PROBLEM STATEMENT: With the proposed initial pipeline output of 709,000 b.p.d. the leak detection system will be sensitive to .5% of the pipeline throughout; this would mean a leak of 3,545 b.p.d. could go undetected by the pipeline company's leak detection system. A leak of this size in an uninhabited area would cause a great amount of damage before it was repaired. (Vol. III, part II; Application for Site Certification, p. 2.11-70) (Vol. I, Application for Site Certification, p. 2-14).

REVIEW COMMENTS: The B. L. M. Environmental Statement states that an oil spill rate of .0022 spills/mile/year is to be expected, while the Northern Tier Pipeline Application for Site Certification states than an oil spill rate of .0012 spills/mile/year can be expected.[1] Use of the B. L. M. data will change the calculation in the Lincoln County notebook under D - 4b. from a spill on the average of once every 21 years to a spill once every 11 years in Lincoln County, if the B. L. M. data is correct.

⑳ The reviewer found nothing in the B. L. M. Environmental Statement about the amount of time needed to close mainline valves in case of a spill.

The volume of an undetectable leak is the same in the B. L. M. document as in the Northern Tier Pipeline Application for Site Certification.[2]

E - 1a. PROBLEM STATEMENT: A two-mile wide pipeline corridor has been chosen by the pipeline company. At this time, the pipeline could be positioned at any place within this corridor. Individuals and agencies will find it difficult to plan, not knowing the exact future position of the pipeline within this corridor.

㉑ REVIEW COMMENTS: In review of the B. L. M. Environmental Statement, no discussion of corridor width or pipeline placement within the two-mile wide corridor was found.

1. B. L. M. Environmental Statement, p. 3-105, Vol. III, part II, NTPL Company Application for Site Certification, p. 2.11-65.
2. B. L. M. Environmental Statement, p. 3-65.

B

ADAMS COUNTY

REVIEW OF DRAFT ENVIRONMENTAL STATEMENT
by the BUREAU OF LAND MANAGEMENT
on the PROPOSED NORTHERN TIER PIPELINE PROJECT

In review of the Bureau of Land Management Environmental Statement, several strong points were revealed. These points are helpful to us in accessing our county's concerns in view of the proposed construction of the Northern Tier Pipeline.

The existance of a waterfowl nesting area at the upper end of Sprague Lake is shown in the B.L.M. document to be significant.[1] Since part of Sprague Lake is in Adams County, this information is of importance to the reviewer in giving us knowledge about how an oil spill could effect waterfowl concentrations in Adams County.

An area in Adams County, along the pipeline route, was shown to have a critical water erosion potential in the B.L.M. document.[2] U.S.D.A. Soil Conservation Service soils data gave us information about the soils in this area; however, it was difficult to intrepret. The B.L.M. study has helped show us the need for extreme erosion control measures in this area.

The general organization of the material in the B.L.M. report was good in that we were able to locate whatever information we needed on the various subjects we studied, among the subjects covered in the B.L.M. report.

In review of the Bureau of Land Management document several weak points were also brought out.

① The report in general was not detailed enough to cover local problems adequately. For example, a map of the pipeline route showing the probability of a pipeline leak mile per mile along the route would have been helpful to the reviewer. The reviewer could better access the adequacy of the proposed placement of mainline through Adams County by the pipeline company with a map like this.

1. Map addendum p. 86 & 87
   Environmental statement p. 2-100

2. Map addendum p. 84 - 87
   Environmental statement p. 3 - 63

The environmental maps in the B.L.M. map addendum in some cases were also not detailed enough to access the characteristics of the entire 2 mile wide pipeline corridor.

② Some of the research done in the B.L.M. document was incomplete. On page 2 - 141 of the Draft Environmental Statement, it states that there are no camper spaces available in Adams County. There are, however, camper spaces available in Adams County; for instance, Bob Lee Campground on Sprague Lake.

③ In some cases, review of the Bureau of Land Management document raised questions. Conflicts of data were found in comparing the B.L.M. document with other sources of information. The main example of this is the conflict in data between the B.L.M. which says ".0022 oil spills/mile/year" are to be expected, and the Northern Tier Company which says ".0012 spills/mile/year" is the expected spill rate along the pipeline route.[1]

1. B.L.M Environmental Statement p. 3 - 105
   Vol. III, part II, NTPL Co. Application for site certification, p. 2.11 - 65

ADEQUACY OF B.L.M. DOCUMENT

in COMPLEMENTING SPECIFIC ADAMS COUNTY PROBLEM STATEMENTS*

A - 1a. PROBLEM STATEMENT: There would be a break in the irrigation schedule, which would damage cropland if the pipeline canal crossing is built during the irrigation season and the East High irrigation canals are in service (Vol. II; Application for Site Certification; p. 6 - 105)

A - 1b. PROBLEM STATEMENT: An oil spill into the proposed East High Canal system would damage hundreds of thousands of acres of cropland downstream in Adams, Grant, Lincoln, and Franklin Counties (U.S.B.R. Columbia Basin Project map; Jan., 1977).

REVIEW COMMENTS: The B.L.M. Environmental Statement made mention of the fact that ground saturated with oil from an oil spill into an irrigation system could take from one to five years to recover, but that cultivation and fertilization would speed this recovery process.[1] Types of crops most susceptible to oil contamination are mentioned, as well as pipeline inconveniences to irrigated land, (leveling, canal construction, etc.) in the B.L.M. document.[2] The B.L.M. made the statement on page 3 - 105, in the Environmental Statement, that 3' may not be a sufficient burial depth for the pipeline in agricultural areas. It was also stated that planning and timing will be needed to lessen pipeline impact on future irrigation projects like the proposed East High project.[3]

1. B.L.M. Environmental Statement p.5 - 21, 3 - 106
2. B.L.M. Environmental Statement p.5 - 21, 3 - 106, 3 - 105
3. B.L.M. Environmental Statement p.1 - 59

*Problem Statements found in Adams County Northern Tier Pipeline Energy Impact Analysis Notebook.

④ The B.L.M. document apparently did not mention how many acres of crops to the south in the proposed East High Canal System would be destroyed if a leak occured into the canal. The B.L.M. evidently did not note any possible ways of lessening the impact of pipeline construction to the canal system, such as construction during a non-agricultural season.

A - 2a. PROBLEM STATEMENT: If an oil spill should occur in Lincoln County, anywhere in area A, the natural slope of the land would drain oil into Adams County and damage cropland (Vol. IV; Application Certification map; p. 806168-806171).

⑤ REVIEW COMMENTS: No supplementary information mentioned in the B.L.M. document on this subject.

A - 3a. PROBLEM STATEMENT: During construction in Lincoln County, and Adams County, roads will be used and possibly damaged, bringing extra maintenance cost to Adams County.

CONT

C - 1a. PROBLEM STATEMENT: Improperly designed pump station access roads will make it more difficult for county services to serve the pipeline pump station.

G - 3a. PROBLEM STATEMENT: Some Adams County roads will be unable to stand the stresses of heavy equipment transportation needed in pipeline construction.

G - 3b. PROBLEM STATEMENT: If the backfill is improperly replaced on public and private road crossings, damage will occur with use by car, truck, and heavy equipment. Improper construction practices could result in undue tension being placed on the pipeline, with a possibility of fracture.

G - 3c. PROBLEM STATEMENT: Future changes of grade on county roads will be more restrictive if the pipeline is placed at a minimum depth under county roads.

⑥ REVIEW COMMENTS: Very little was mentioned by the B.L.M. about sharing responsibility on road maintenance costs or services. The Forest Service statements on page 4 - 7 in the B.L.M. document mentioned the need for maintenance standards and responsibility during pipeline construction and operation.

This review located nothing in the B.L.M. Environmental Statement about the problem of future road grade changes and their restriction by pipeline placement.

An improperly rebuilt roadbed (public or private) over the pipeline could place undue tension on the pipeline. This factor was apparently not mentioned in the B.L.M. document.

The B.L.M. document did discuss road use damage or delay during pipeline construction or spill cleanup.[1]

Alternatives such as load limit restrictions, placement of shield pipes, extra pipeline depth, and improved roadbed construction were evidently not specifically dealt with in the B.L.M. statement.

E - 1a. PROBLEM STATEMENT: In rangeland areas it has been shown that when native grasses are destroyed during construction, inferior grasses such as cheat grass will invade construction areas (Vol. III, Part 1; Application for Site Certification; p. 2. 4 - 29).

REVIEW COMMENTS: In the B.L.M. Environmental Statement on page 4 - 4 the lack of mitigating measures dealing with revegetation is discussed. They suggest reseeding with natural vegetation on page 5 - 16 of the report, which is in line with local desires. Methods of reseeding are discussed in the B.L.M. document also.[1]

⑦ The Pipeline System, Vegetation Impact table on page 3 - 81 of the Environmental Statement is difficult to interpret for our use. Apparently nothing is mentioned in the statement about our area's specific problem of cheatgrass taking over after natural wheatgrass has been destroyed during construction. That rangeland areas could revegetate with undesirable species is mentioned, but in the reviewer's opinion, rangeland almost certainly would revegetate with undesirable species after pipeline construction.[2]

Adams County is not mentioned in the natural vegetation table on pages 3 - 82 and 3 - 83, and it should be.

In general, the rangeland vegetation problem in Adams County is only partially covered in the B.L.M. Environmental Statement.

1. B.L.M. Environmental Statement p. 4 - 4
2. B.L.M. Environmental Statement p. 3 - 104

E - 2a. Some of this area is characterized by soil with a permeable gravel underlay where a small pipeline leak of 2 - 5 gpm would go undetected at the surface of the ground, thereby polluting the environment (Vo. II, Part II; Application for Site Certification; p. 2.11 - 70; and Adams County Soils Survey, map; p. 8).

⑧ REVIEW COMMENTS: Soil types and characteristics are discussed in some detail in the B.L.M. Environmental Statement; permeability is also discussed to some degree.[1] No apparent discussion is made on the subject of oil permeability in soils, however, in the B.L.M. document.

E - 3a. PROBLEM STATEMENT: Open pipeline trench or construction equipment will harm or restrict range animals during pipeline construction.

REVIEW COMMENTS: The B.L.M. Environmental Statement mentions that open pipeline trench and construction equipment operation could cause livestock injuries or fatalities.[2] On page 1 - 44 in the B.L.M. document it states that the pipeline trench will be open for as short a time as possible. ⑨ The reviewer found nothing in the B.L.M. report about skipping sections during construction so range animal movement would not be hindered.

F - 3a. PROBLEM STATEMENT: An insufficient number of block and check valves are currently proposed for the Sprague Lake drainage area, increasing the probable volume of an oil spill in that area (Vol. IV; Application for Site Certification; p. 806170).

REVIEW COMMENTS: The characteristics and location of mainline valves are given in the B.L.M. Environmental Statement on pages 1 - 24 and 1 - 25.

As mentioned earlier, the reviewer would be in favor of a map or list showing areas where the probability of an oil leak or spill would be greater than the pipeline average. With this information, Adams County personnel could plan, with the use of topographic data, where block and check valves should be placed in Adams County.

1. B.L.M. Map Addendum, p. 84 - 87 and p. 127 - 128
   B.L.M. Environmental Statement p. 2 - 54 to 2 - 55
2. B.L.M. Environmental Statement p. 3 - 104

⑩ Department of Transportation regulations regarding the placement of mainline valves are discussed; however, no indication of adequacy in protecting Adams County is given in the B.L.M. document.[1]

G - 1a. PROBLEM STATEMENT: Future county development will be hindered by placing the pipeline in an area where the pipeline would conflict with future land use designs.

82
CONT

REVIEW COMMENT: Land use and comprehensive plan studies are generally already mitigated through local land use hearings. No shoreline management areas are crossed in Adams County. Some coverage of these factors are found in the B.L.M. document.[2]

G - 1b. PROBLEM STATEMENT: Crude oil is forecast to be a primary energy source for the U. S. through 1990's. If the pipeline is only to be used for a short time, losses in county goods and services will outweigh benefits (Vol. II, Application for Site Certification, p. 6 - 205).

REVIEW COMMENTS: Alternative proposals for crude oil transportation are described in the B.L.M. document.

⑪ Alternative energy sources, which might eliminate or lessen the need for a petroleum pipeline in future years are also apparently not mentioned in the B.L.M. study.

G - 2a. PROBLEM STATEMENT: When conflicts arise with the pipeline company, it may be uneconomical for agencies or individuals to recover damages due them because of the substantial legal resources of the pipeline company.

⑫ REVIEW COMMENTS: The use of a mediating board or other third party legal processes to resolve conflicts between counties and the pipeline company was apparently not discussed in the B.L.M. Environmental Statement. In the reviewer's opinion, the problem of legal processes is a very real concern when dealing with an agency as large as the pipeline company.

1. B.L.M. Environmental Statement p. 1 - 24 and 1 - 25
2. B.L.M. Environmental Statement pages 3 - 102, 3 - 104 and 1 - 61.

G - 2b. PROBLEM STATEMENT: The "Oil Spill Contingency Plan" has not been made public. This leaves the agencies and individuals of our county uninformed about how oil spills will be cleaned up and who will pay for their cleanup. (Vol. II; Application for Site Certification, p. 6 - 1 - 134) (Vol. III, Part II; Application for Site Certification; p. 5 - 31).

⑬ REVIEW COMMENTS: The B.L.M. document quite extensively discusses the Oil Spill Contingency Plan and the elements it will contain when it is released.[1] It did not say exactly when the Oil Spill Contingency Plan would be brought out, nor how much control Adams County would have in revising the Contingency Plan if it is not adequately protective of County property.

G - 3d. PROBLEM STATEMENT: Land leveling or deep ripping to break up hardpan would damage the pipeline if farmers work the soil deeper than the proposed minimum pipeline depth of 36". (Vol. 1; Application for Site Certification, pages 2 - 14).

REVIEW COMMENTS: In the B.L.M. Environmental Statement on page 3 - 105, it states that a burial depth of 3' will be restrictive to certain agricultural activities. Included in the list of restricted agricultural activities is land leveling, irrigation ditch construction, and border type irrigation. The document cites the proposed East High Canal System as an example of a potentially affected area.

G - 3e. PROBLEM STATEMENT: Adams County government and citizens will need to provide extra services such as housing, law enforcement, health, fire protection; school space and other services during pipeline construction.[2] Probable short term increases in population for cities along the pipeline route include: 16.9% for Ritzville, 7.9% for Lind, and 5.3% for Othello.[3]

1. B.L.M. Environmental Statement p. 1 - 54
2. (Vol. III part II; Application for Site Certification, pages 5 - 53, 5 - 54).
3. (Vol. III part II; Application for Site Certification, pages 2.12 - 63) (Vol. III part I, Application for Site Certification, pages 1.13 - 17).

REVIEW COMMENTS: Current information on housing, rental units, cam per space, medical services, police protection and fire protection, is given in the B.L.M. document.[1] ⑭ At least some of this information is inaccurate, such as the table on page 2 - 141 that states that there is no available camper space in Adams County.

Construction work force impact by month is given by pipeline section on page 3 - 120 of the B.L.M. document. On page 3 - 122 and 3 - 123, very useful information is given on transient population, construction work force, and construction employment by county. The B.L.M. makes note of the fact that the Northern Tier Pipeline Company will provide its own housing where needed.[2]

G - 3f. PROBLEM STATEMENT: The major portion of pipeline construction will take place from April through November 1980; this will have an adverse affect on agricultural activities; especially on wheat harvest. (Vol. II; Application for Site Certification, p. 6 - 105).

⑮ REVIEW COMMENTS: Traffic delays to adjoining land uses are mentioned as an impact of pipeline construction or spill cleanup.[3] In the reviewer's search, nothing was found in the B.L.M. document specifically about possible holdup of agricultural activities due to road blockage during pipeline construction. It is very important that detours be used to keep roads open during pipeline construction activities, so that harvest will not be delayed.

G - 3g. PROBLEM STATEMENT: The pipeline company has not shown where material sites, for rock-free fill material or waste dump sites, will be located. Improper location of such sites will be unsightly and perhaps erosive. (Vol. III part II, Application for Site Certification p. 5 - 27).

REVIEW COMMENTS: The B.L.M. Environmental Statement mentions general areas of location and reclamation of borrow sites.[4]

1. B.L.M. Environmental Statement p. 2 - 141
2. B.L.M. Environmental Statement p. 4 - 8
3. B.L.M. Environmental Statement p. 5 - 20
4. B.L.M. Environmental Statement p. 4 - 2

G - 3i. PROBLEM STATEMENT: No statements about dust control in rural areas were made by the pipeline company; dust (wind erosion) removes a large amount of farmable topsoil from the land.

CONT

REVIEW COMMENTS: A wind erosion map provided by the B.L.M. on pages 84-87 of the B.L.M. Map Addendum shows a significant amount of wind erosion could occur in parts of Adams County. Wind erosion in lbs./acre is covered on pages 3 - 63 and 3 - 64 of the B.L.M. Environmental Statement in Adams County. Watering and mulching disturbed soil are mentioned as mitigating factors on page 4 - 2 of the B. L. M. Environmental Statement.

G - 3j. PROBLEM STATEMENT: Many of the wheatland, loessial soils, through which the pipeline will pass, are subject to erosion during severe runoff periods. Gullies or slumps will expose the pipeline during times of severe erosion, especially right after construction when the fresh pipeline backfill has not yet compacted. (Vol. III, part II; Application for Site Certification, pages 5 - 24).

REVIEW COMMENTS: The erosive character of the loessial soils in Adams County is brought to our attention in the B.L.M. Map Addendum on pages 84 - 87. On page 4 - 2 of the B.L.M. Environmental Statement, a measure which would have the pipeline avoid areas of high potential for mass failure is proposed by the U. S. Forest Service. The B.L.M. document is accurate in that it shows little or no potential for mass failure in Adams County.

⑯ One soil problem which exists in Adams County that has not yet been brought to attention is the low cohesive strength of the Ritzville soil types through which the pipeline will pass. According to Adams County USDA S.C.S. Soil Survey Engineering Interpretations, published after 1970, slope cave-in danger is critical on these soils when excavated or trenched. Since the depth of the proposed Northern Tier Pipeline trench is at least 78", safety hazards to workers in the trench are to be expected. The Soil Conservation Service information recommends sloping the sides of the trenches in these Ritzville soil types, and any soil which lacks cohesive strength, as a safety measure.

G - 3k. PROBLEM STATEMENT: The safety of children and adults near the pipeline construction right-of-way will be endangered by construction activities.

⑰ REVIEW COMMENTS: No specific statements about safety during construction, near the pipeline right-of-way, was found in the B.L.M. Environmental Statement by this review.

G - 3m. PROBLEM STATEMENT: Sabotage is possible on the pipeline if it is placed above the ground at canal or stream crossings. (Vol. II; Application for Site Certification, p. 6 - 60).

⑱ REVIEW COMMENTS: The possibility of sabotage at an overhead pipeline-canal crossing is mentioned on page 3 - 106 in the B.L.M. Environmental Statement. Mitigating measures dealing with this problem were not found in the B.L.M. document by the reviewer.

G - 3n. PROBLEM STATEMENT: Utilities services will be cut off to local residents if the pipeline company accidently severs utility lines during excavation for pipeline construction.

REVIEW COMMENTS: The possibility of damage to utility systems is discussed in the B.L.M. Environmental Statement on page 5 - 21. An oil spill or oil spill cleanup may cause damage to a nearby utility or transportation system, according to the B.L.M.[1] The B.L.M. states, on page 3 - 107 of their Environmental Statement, that pipeline construction and pipeline electrical use might interfere with possible expansion of electrical transmission systems.

The fact that close coordination would be maintained between the pipeline company and the other utility companies through crossing and joint use permits is mentioned by the B.L.M.[2]

G - 4a. PROBLEM STATEMENT: Ten minutes will be needed to shut the pipeline off and close mainline valves in case of a pipeline break; the volume of oil spilled in this period of time would be enormous, in the event of a pipeline rupture. (Vol. II; Application for Site Certification, p. 6 - 102).

1. B.L.M. Environmental Statement, p. 5 - 22, p. 3 -107
2. B.L.M. Environmental Statement, p. 5 - 21

G - 4b. PROBLEM STATEMENT: Based on data from existing oil pipeline, oil spills of an average volume of 2,747 barrels per spill can be expected once ever 54 years in Adams County; one such spill would damage a large area of land. (Vol. I; Application for Site Certification, pages 2 - 55 and 2.11 - 65). (Vol. III, part II, Application for Site Certification, page 2.11 - 70).

G - 4c. PROBLEM STATEMENT: With the proposed initial pipeline output of 709,000 b.p.d., the leak detection system will be sensitive to .5% of the pipeline throughout; this would mean a leak of 3,545 b.p.d. could go undetected by the pipeline company's leak detection system. A leak of this size in an uninhabited area would cause a great amount of damage before it was repaired. (Vol. I, Application for Site Certification, p. 2 - 14), (Vol. III - part II, Application for Site Certification, p. 2.11 - 70).

⑲ REVIEW COMMENTS: The B.L.M. Environmental Statement states that an oil spill rate of .0022 spills/mile/year is to be expected, while the Northern Tier Pipeline Application for Site Certification states than an oil spill rate of .0012 spills/mile/year can be expected.[1] Use of the B.L.M. data will change the calculations in the Adams County notebook under G - 4b. from a spill on the average of once every 54 years to a spill once every 28 years in Adams County, if the B.L.M. spill rate is correct.

The reviewer found nothing in the B.L.M. Environmental Statement about the amount of time needed to close mainline valves in case of a spill.

The volume of an undetectable leak is the same in the B.L.M. document as in the Northern Tier Pipeline Application for Site Certification.[2]

1. B.L.M. Environmental Statement p. 3 - 105, Vol. III, part II, NTPL Company Application for Site Certification, p. 2.11 - 65.
2. B.L.M. Environmental Statement p. 3 - 65

H - 1a. PROBLEM STATEMENT: A two-mile wide pipeline corridor has been chosen by the pipeline company. At this time, the pipeline could be positioned at any place within this corridor. Individuals and agencies will find it difficult to plan, not knowing the exact future position of the pipeline within this corridor.

⑳ REVIEW COMMENTS: In review of the B.L.M. Environmental Statement, no discussion of corridor width or pipeline placement within the two-mile wide corridor was found.

G - 3h. PROBLEM STATEMENT: The Northern Tier Pipeline Company was not specific at what maximum pipeline slope they would begin placing erosion control devices or materials to help control erosion in the pipeline trench, should a large runoff period occur.

㉑ REVIEW COMMENTS: Detail discussion of erosion amounts per acres was given in the B. L. M. document as well as other related erosion problems. No specific discussion on placement of pipeline trench erosion control devices was found in the B. L. M. document by this review.

Portland, Oregon 97232

Dear Mr. Leonard:

As you know, the Montana Department of Natural Resources and Conservation is currently preparing an environmental impact statement on the proposed Northern Tier Pipeline in Montana. Throughout the process the Department of Natural Resources and Conservation has been working closely with your staff and will continue to do so until completion of both studies.

In light of this cooperation, and the fact that the state's EIS is not yet completed, I do not feel it is necessary or appropriate for the State of Montana to comment on the Federal draft environmental impact statement.

Sincerely,

Thomas L. Judge

Bureau of Land Management
Northern Tier Project
Room 1250 - Lloyd Building
700 NE Multnomah
Portland, OR 97232

Gentlemen:

Northern Tier Pipeline Company (NTPC) has conducted a comprehensive review of the Draft Environmental Statement produced by the Bureau of Land Management on our proposed crude oil transportation system. NTPC is pleased that the BLM and other government agencies (federal, state and local) have developed an informative and detailed DES on our proposal. The BLM is to be commended for the timely completion of the DES in light of the magnitude of the undertaking. We appreciate the flexibility shown by the BLM's ES Team in adjusting to the changes in Northern Tier's proposal as we have responded to valid environmental concerns identified during the environmental review process. We think that this is a direct manifestation of the intent of the National Environmental Policy Act. The most important thing to say about the DES and the ES processes, as carried out by the BLM, is that it has and is continuing to work as intended. NTPC has and will continue to work closely with the BLM to provide pertinent engineering and environmental data to insure the best statement possible and to incorporate mitigation measures which respond to valid environmental concerns.

The attached communication from Environmental Research and Technology, Inc. to NTPC constitutes the substantiative technical comments by Northern Tier Pipeline Company on the DES. It is to be considered as a statement of NTPC for this purpose, and we request that the comments be considered in the development of the Final ES.

It is the intent of NTPC to construct and operate this vital transportation system which will provide an assured supply of petroleum products to agriculture, business, industry and each consumer in the Northern Tier and inland states. We appreciate the participation of the BLM in the review and development of this proposal.

Bureau of Land Management

MEMORANDUM

TO: T. C. Kryzer
MEMO NO.: BMT-77
FROM: Max C. Deibert
DOC. NO.:
DATE: 29 March 1979
SUBJECT: Detailed Review Comments on the BLM Draft Environmental Statement. Crude Oil Transportation System As Prepared By NTPC.

INTRODUCTION

As authorized by you, the Bureau of Land Management (BLM) Draft Environmental Statement (DES) on the proposed Northern Tier Pipeline Company (NTPC) crude oil transportation system (dated 3 January 1979) has been reviewed and comments have been prepared for submission to BLM prior to 2 April 1979, the closing date of the public comment period on the DES.

This memo contains both a summary of general comments and a detailed list of specific comments with direct citation to the BLM DES text. The specific comments are organized primarily by environmental discipline, but additional comments are provided for the Executive Summary and for the Project Description and Alternatives chapters.

The outline of the response is as follows:

- INTRODUCTION
- GENERAL COMMENTS
- SPECIFIC COMMENTS:
  - Executive Summary
  - Description of the Proposed Action
  - Climate and Air Quality
  - Noise
  - Topography, Geology and Soils
  - Ecology (including Aquatic and Marine Resources and Terrestrial Vegetation and Wildlife)
  - Oil Spills
  - Cultural Resources
  - Visual and Recreation Resources
  - Land Use
  - Transportation and Utility Networks
  - Social and Economic Conditions
  - Alternatives to the Proposed Action

T. C. Kryzer - Memo BMT-77
29 March 1979
Page 2

Reviewers on behalf of NTPC included personnel from Environmental Research & Technology, Inc. (ERT), Butler Associates and the law firm of Preston, Thorgrimson, Ellis, Holman and Fletcher.

## GENERAL COMMENTS

In general, the analysis is comprehensive, thorough, and reasonably consistent with data and information generated by NTPC concerning the project. Furthermore, the conclusions reached in the assessment of impacts are reasonably consistent with those reached by NTPC and its consultants. There are, however, several issues for which comment by NTPC is warranted.

1) There is a general need to provide clarification of conclusions reached, methods used in reaching conclusions or conducting analyses, and assumptions made in the analyses. As pointed out in the "specific comments" below, it is not always clear how a conclusion was reached, usually because not enough description was given of the assumptions and analysis methods to allow the reader to confirm the conclusion on the basis of the given baseline data.
2) Occasionally there is an inconsistency between basic project data used by BLM in the DES and that generated and/or provided by NTPC. This includes schedule information as well as quantitative data. Likewise, there is occasionally an inconsistency between data used for the same purpose in different parts of the DES. On this issue, the acreage of the Green Point site deserves special mention. The NTPC has title to only 242 acres. Because of a "reverse option," NTPC could be required at a future date to acquire an additional 52 acres, bringing the total to 294 acres. Thus, the Green Point site is referred to as having 242 acres. Other examples are noted under the "specific comments."
3) There are occasional inconsistencies between the impact conclusions reached in the DES and those reached by NTPC as documented in its Application for Site Certification, submitted to the Washington Energy Facility Site Evaluation Council (the NTPC EFSEC Application) dated 18 August 1978. In some cases, we believe that the DES overstates the degree of impact because of extreme conservatism (that is, use of unrealistic worst-case conditions). In other cases, we believe there may have been a computational error. As noted in Item 1, however, it is often not possible to follow through the procedure used to arrive at the impact conclusion.
4) The BLM DES does not provide a complete listing of the mitigation measures that have been committed to by NTPC and that are documented in the NTPC EFSEC Application. Moreover, while some of the NTPC mitigation measures have been incorporated into the BLM analysis of project impacts, others have not and are listed separately in Chapter 4. A consistent treatment of committed NTPC mitigation measures is recommended.
5) It is also recommended that the BLM provide additional details on the provisions of the Public Utility Regulatory Policies Act of 1978, Title V, Crude Oil Transportation Systems, specifically to describe what effect the Act will have on environmental studies, project schedules, consideration of other proposals, and the like.
6) In response to impacts identified by NTPC (for example, in the NTPC EFSEC Application) and to concerns expressed by agencies and the public, NTPC has been studying the feasibility of various "potential mitigation measures" described in the NTPC EFSEC Application, as well as additional pipeline route alternatives, and is currently in the process of making changes that will incorporate several of these mitigation measures. Among these are changes to the submarine pipeline approach at Green Point to avoid the cut in the bluff and changes in the method of bunkering to avoid the use of a large number of small bunker supply barges in Puget Sound. While these measures will largely reduce the corresponding impacts described in the BLM DES, the NTPC review comments focus solely on the proposed action as described and studied in the DES.

All of these issues are addressed below in more detail with reference to specific portions of the BLM DES text.

Executive Summary

① In general, the comments made in the following sections concerning the body of the DES also pertain to the Executive Summary, and corrections made to the DES should be reflected in the Executive Summary. A majority of comments relate to the accuracy of the project description. For example, the entire description must include facts and figures on the Jackass Ridge and Nine Mile Creek/Missoula-to-Helmville primary route. Other specific comments follow.

| Page, Column, Paragraph | Comment |
|---|---|
| 1, C1, P1 | The total mileage should be 1,560 instead of 1,557. |
| 2, C1, P3 | The 20% of refinery capacity numbers for 215,400 barrels per day (bpd) in 1990 and 214,300 bpd in 2000 do not appear to be consistent. |
| 2 and 3 | Dates of various activities need to be revised and mention made of provisions of Title V, Public Utility Regulatory Policies Act. |
| 5 | Route I on Figure 1 should be labeled. Figure 1 also shows an airport at the eastern end of Ediz Hook. Contact with the USCG indicates that there are presently no fixed-wing aircraft operations (nor have there been any during the last several years) and only limited helicopter operations. It would be more accurate to refer to the area as USCG facilities. |
| 10 and 11 | The map for Nine Mile Creek/Missoula-to-Helmville should be revised. |
| 12, C1, P5 | The NTPC has title to only 242 acres at Green Point. |
| 21, C1, P4 | The assumptions concerning sulfur content of bunkering fuel used in the analysis should be stated. The information presented in this paragraph is confusing and appears to be inconsistent with data from Table 3.1.2.7 (page 3-4 of DES). (See also Air Quality comments concerning page 2-4, C1, P4.) |
| 28 and 29 | The retouched photograph of the proposed excavation in the Green Point bluff appears somewhat exaggerated at the top of the bluff, and the superimposed tanks appear somewhat elevated above the ground surface. The NTPC analysis indicates the primary viewing points, north of Green Point in the strait, will be from boats at sea level. Therefore, the retouched photograph is somewhat misleading in portraying an aerial oblique view offshore of the bluff excavation and storage tanks. |
| 29, C2, P1 | The statement that: "During operation of the onshore storage facilities there would be substantial impact on visual or aesthetic values" is misleading. The NTPC analysis indicates that the views of the site from offsite are restricted (see Figure III-1.10-1 in the NTPC EFSEC Application) and that, consequently, the overall aesthetic impact of the onshore storage site (excepting the bluff excavation) is somewhat less than that indicated in the BLM DES. |
| 30, C1, P2 | Although local utility companies are certainly concerned, the statement that "the demand for power would be a substantial impact on existing and future electrical facilities and supply," is misleading regarding power requirements of proposed NTPC facilities in Clallam County. An analysis of this issue prepared for NTPC suggests that NTPC-related power demands would not adversely affect the cost nor the availability of power in Clallam County for two reasons: (1) the nature of the regional power pool (the "one short, all short" arrangement for pooling of resources) and (2) the NTPC-related power demands represent a small proportion of total regional load growth. |
| 33, C1, P3 | The mitigating measures mentioned in paragraph 3, such as to construct during low flows and to avoid spawning season, have been committed to by NTPC. |
| 33, C2, P3 | The discussion of the Flathead Reservation should be omitted since it is no longer on the primary route. |
| 35, C1, P1 | Water withdrawal and discharge mitigation measures have been committed to by NTPC. |
| 37 | Columns 1 and 2 appear to be in reverse order. |
| 41 | The statement that 294 acres are cleared at Green Point is incorrect; only about 140 acres on the 242-acre site are to be cleared. The NTPC does not have title to the remaining (294 less 242) 52 acres. |
| 50, C2, P2 | See the comment made for page B-4 of DES regarding circling of Cedar River watershed by Stampede Pass alternative route. |
| 52 | The descriptions should be changed to address new primary routes. |
| 56 | Figure 14 - Seadock should be the "LOOP" project. |
| 57 and 62 | Description of Trans-Mountain Pipeline, Kitimat Pipeline, and Foothills Pipeline proposals should be revised to include a description of their Title V applications. |
| 63, C1, P4 | See the comment made for page B-4 of the DES Alternatives chapter regarding the capability of the Mid-Continent Pipeline System to be expanded by 875,000 bpd. It should be noted that Northern Tier states west of Minnesota cannot be supplied by the Mid-Continent Pipeline System. |

Description of the Proposed Action

② The following comments relate primarily to Chapter 1 of the DES but also include corrections relating to the project description occurring elsewhere in the DES, including the Map Addendum.

| Page, Column, Paragraph | Comment |
|---|---|
| Chapter 1 | The entire description must include facts and figures for the Jackass Ridge and Nine Mile Creek/Missoula-to-Helmville alternative. The new pipe length is 1,560 miles, and the following tables will be revised by Butler Associates on behalf of NTPC. The changes are minor and therefore only have a minor impact on the overall plans.<br>Table 1.4-3, page 1-16, Federal Lands<br>Table 1.4-4, page 1-17, Pipeline Mileage<br>page 1-18, Description of Jackass Ridge and Nine Mile Creek<br>Table 1.4-5, page 1-19, Pipe Tonnage<br>Table 1.4-6, pages 1-19, 20, and 21, Major Highway/Railroad Crossings<br>Table 1.4-7, page 1-21, Major Stream and River Crossings<br>Table 1.4-8, page 1-22, Minor Crossings<br>Table 1.4-9, page 1-23, Irrigation Canal Crossings<br>Table 1.4-10, page 1-23, Unaffiliated Pipeline Crossings<br>Table 1.4-11, page 1-24, Utility Corridors<br>Table 1.4-12, page 1-25, Location of Valves<br>Table 1.4-13, page 1-27, Location of Pump Stations<br>Table 1.4-14, page 1-31, Pump Station Horsepower<br>Table 1.4-15, page 1-32, Pump station Power Requirements<br>Table 1.4-16, page 1-38, Construction Stockpile<br>Table 1.4-17, page 1-39, Construction Material<br>Table 1.4-19, page 1-42, Pipeline Section Parameters<br>Table 1.4-22, page 1-51, Summary of Cost Pipeline<br>Table 1.4-23, page 1-51, Summary of Cost Unloading Facilities<br>Table 1.4-24, page 1-52, Summary of Cost Onshore Storage<br>Table 1.4-26, page 1-53, Summary of Cost All Facilities<br>Table 1.5-1, page 1-61, Planning and Zoning |
| 1-56, C1, P3 | This paragraph should read: "As soon as the dispatcher had shut down the pipeline system and closed the appropriate, remotely controlled block valves, the appropriate response personnel in the Spill Contingency Plan would be notified." |
| 1-56, C1, P5 | This paragraph should read: "One or more employees would go to the site to confirm and pinpoint the rupture, initiate the appropriate plan to protect the public, and begin containment." |
| 1-58 | Item 22 should read: "Stream flow control measures such as river training works or channelization will be avoided in all areas of pipeline crossings.<br>"Anticipated effectiveness: The current or natural flow character of the streams and rivers will be undisturbed by the pipeline." |
| 1-58 | Add a new Item 29 to read: "Northern Tier Pipeline Company will install a remote means of actuation at all mainline block valves.<br>"Anticipated effectiveness: This will ensure that during an emergency, sections of the pipeline could be isolated by closing the block valves to [illegible] and minimize potential drainage." |
| 1-58 | Add a new Item 30 to read: "Major stream crossings by the pipeline will be constructed during a three-month period designated by the appropriate state agency responsible for the protection of fish and wildlife.<br>"Anticipated effectiveness: This action will minimize impact on fish and wildlife during construction." |
| 1-61 and 1-62 | Description of the Trans-Mountain Pipeline and Kitimat Pipeline proposals should be revised to include a description of their Title V applications. A description of the Foothills Pipeline proposal should be added. |
| 2-26, C1, P2 | Note that NTPC has title to only 242 acres (not 294 acres) for the onshore storage site. |
| 2-45 | Should the picture caption be Port Angeles rather than Port Orchard? |
| 2-57, C1, P1 | Item 4 should be pipeline mile 1,560 rather than pipeline mile 1,565. |
| 2-117 | The segment 11 heading should change 1,565 to 1,560 miles. |
| 3-7, C1, P1 | It is our opinion that these crude oil storage temperatures are higher than will be experienced, especially for foreign crudes. |
| 3-11, C1, P5 and 3-14, C2, P7 | It is unlikely that on abandonment the topography of the onshore storage facilities site would be fully returned to its original condition. |
| 3-58, C1, P4 | Grading and leveling would alter a maximum of 4 to 7 acres for each pump station. |
| 3-87, C1, P2 | The NTPC will not install new microwave transmission facilities. The NTPC proposes to use a leased-line system for control and communications to pump stations and remote block valve sites. This leased-line system may incorporate microwave links but it is not anticipated that new microwave facilities would be required. |
| 5-3, C2, P1, and 5-4, C2, P8, and 6-2, C1, P6 | Green Point acres should be changed from 294 to 242. |
| Map Addendum | The following maps must be revised for the Jackass Ridge, Nine Mile Creek/Missoula-to-Helmville route:<br>Pages 3 through 23<br>Pages 67, 89, 90, 91, 92, 93, 94, and 95 |
| Map Addendum pg. 77 | The BLM map shows the pipeline following the transmission right-of-way northwest and west of the town of Eldon. The NTPC maps show the pipeline leaving the transmission right-of-way northwest of the town and continuing southerly. |
| Map Addendum pg. 77 | The BLM maps shows pump station 2 south of Isabella Lake. The NTPC maps show pump station 2 approximately 1 mile north of Isabella Lake. |
| Map Addendum pg. 77 | The BLM map shows pipeline following the transmission right-of-way south of Isabella Lake. The NTPC maps show pipeline leaving the transmission right-of-way at Isabella Lake and paralleling the Northwest Pipeline right-of-way. |

Climate and Air Quality

③ Overall, the major issues have been addressed and the results have been presented in an objective manner. However, to improve the analysis, it is suggested that some idea be given on the uncertainty in the model calculations when one is comparing the results with Ambient Air Quality Standards (AAQS) or Prevention of Significant Deterioration (PSD) increments. Also, it is noted that throughout the report a comparison is made between nitrogen oxide ($NO_x$) concentrations and the AAQS for nitrogen dioxide ($NO_2$). Nitrogen oxides are composed of nitric oxide (NO) and $NO_2$. There is no AAQS for NO. Therefore, it is meaningless to compare $NO_x$ air quality with an AAQS for $NO_2$. Finally, it is noted that enough information exists regarding present emissions in Port Angeles to allow mathematical modeling of baseline air quality for some pollutants. This would be helpful to evaluate compliance with AAQS without the project. Additional comments include the following.

| Page, Column, Paragraph | Comment |
|---|---|
| ④ 2-3 | Explain that the hydrocarbon (HC) standard is for 6:00 to 9:00 A.M. and is only a guide to limit ozone production. The term HC refers specifically to nonmethane hydrocarbons. |
| ⑤ 2-4, C1, P4 and 3-4, C2, P2 | The question of whether the Heart O' the Hills parkway corridor is within the Olympic National Park boundary for PSD purposes is a legal question that has not been resolved. If it is not, then PSD Class I increments do not apply. If it is, then the question of variance from Class I increments does not depend on the shape of the corridor but rather on whether it contains the specific attributes of dramatic vistas, wilderness |

84 CONT.

⑤ character, and other air quality-related values that were intended to be protected by the PSD Class I requirements. Under the circumstances,

| Page, Column, Paragraph | Comment |
|---|---|
| | NTPC believes that it is appropriate to compare sulfur dioxide ($SO_2$) concentrations with both Class I and Class II PSD increments but that it is premature to assert that Class I increments definitely apply. Moreover, the statement that "irregularity of shape does not allow a variance with Class I standards" is meaningless and should be deleted. |
| 2-4 | The heading of Table 2.1.1.2-3 should be "major industrial sources of air pollutant emissions..." (Note $SO^2$ and $NO^x$ should be $SO_2$ and $NO_x$.) |
| ⑥ 2-33, C2, P4 | The text associated with Table 2.1.2.2-1 states that ozone air quality in the Seattle area has been as high as 0.17 ppm (340 $\mu g/m^3$). In the table, a value of 120 $\mu g/m^3$ is shown for 1975. This discrepancy needs clarification. |
| ⑦ 2-150, C1, P2 | The statement concerning the reduction of pollutant levels in urban areas is too general. While it is generally true that CO and $SO_2$ ambient levels have been decreasing, ozone levels have been increasing generally in the last decade. |
| ⑧ 3-2, C1, P2 | How do the annual average $SO_2$ levels compare with the annual AAQS? |
| ⑨ 3-4, C2, P2 | What is the uncertainty in the model predictions for $SO_2$? This is important in assessing the significance of the estimated frequency of violation of Class I PSD increments for $SO_2$ in Olympic National Park. |
| ⑩ 3-6, C1, P1 | This paragraph confuses the issue of $NO_x$ and $NO_2$. Clarification is needed because of the general comments given above. |
| ⑪ 3-6, C1, P3 | The HC standard is for the 6:00 to 9:00 A.M. 3-hour period. |

| Page, Column, Paragraph | Comment |
|---|---|
| ⑫ 3-7, C1, P1 | Why does API Bulletin 2517 significantly overestimate the emissions? Some background on this is appropriate. |
| ⑬ 3-7, C1, P3 | Nitrogen oxides are composed of NO and $NO_2$. Nitrogen oxides in general do not remove ozone rapidly; only NO does this. The paragraph should make this clear. |

## Noise

Review of those sections of the DES concerning noise indicated no serious omissions or errors.

## Topography, Geology, and Soils

The following changes are recommended to improve the accuracy and clarity of information presented.

The soils information provided is comprehensive and essentially complete but would benefit from a reduction in text through tabulation of numerical data so that a ready comparision of potential impacts would be possible. In addition, the following items require attention.

| Page, Column, Paragraph | Comment |
|---|---|
| ⑭ 3-64, C1, P3 | The sentence: "Severe erosion is a common occurrence on summer fallowed wheatland in this area and is indicative of what would occur following pipeline construction." is not accurate because of the relative scale of large plowed fields in comparison to a narrow pipeline right-of-way. |
| ⑮ 3-65, C1, P7 | An introductory sentence relating hydrostatic testing effects to potential soils impact is needed for clarification of the information presented. |
| ⑯ 5-13, C2, P5 | The statement: "Average soil losses from fugitive dust would be 80 to [illegible] pounds per acre of pipeline right-of-way and would not be mitigated by water application except in urban areas and on U.S. Bureau of Reclamation lands." is in error because the water will provide fugitive dust mitigation wherever it is applied for this purpose. The statement also contradicts statement 4 on page 4-2. |

The geological information provided is sufficient but would benefit from a more objective and less dramatic impact evaluation. In particular, the following items require attention.

CONT.

| Page, Column, Paragraph | Comment |
|---|---|
| ⑰ 2-11 | Slope stability at Green Point and Ediz Hook is mishandled in the document, and the erosion rate of the bluff established by Shannon & Wilson (1978) is disregarded. Instability is claimed on pages 2-11, 2-12, 3-11, and 3-12 but a stable condition is stated elsewhere on page 3-12 and Plate III-3 on page 55 of the Map Addendum. Clarification is required, and the clarification should be carried to Tables 5.1.4-1, 5.2.4-1, and Table 6 of the Summary. |
| ⑱ 5-14 | Table 5.2.4-1 and related text indicates that as much as 1,600,000 cubic yards of rock per mile may be excavated. It is very unlikely that any such volume of rock would be excavated, even for long, side-hill traverses in steep terrain where benching would be necessary. Benching in solid rock does not require wide slopes for stability, and it is unlikely that side-hill traverses of 1-mile lengths will be encountered during construction because route selection has specifically avoided such conditions. |
| ⑲ 6-2, C2, P4 | No data or rationalization is presented to support the statement that changes of erosion rates at Green Point will affect sedimentation at Dungeness Spit. While it seems logical that some change could occur, calculations of worst-case conditions indicate that perhaps 350 cubic yards of bluff material could be affected each year (or about 7,000 cubic yards total during a 20-year project lifetime). This volume is not significant in comparison to the millions of cubic yards of material that would be transported longshore during this period of time, and there has been no established erosion-sedimentation tie between Green Point and Dungeness Spit. The statement should be either supported or deleted. |
| ⑳ 2-11 | The Table 2.1.1.4-2 description of level VIII is not consistent with descriptions before and after. |
| 2-12 | Table 2.1.1.4-3 is either mistitled or in error. Richter magnitude does not include an estimate of damage to structures or human response to seismic disturbances. "Intensity" rather than "magnitude" is the appropriate terminology for damage and response conditions. |
| ㉑ 2-52, C1, P2 | Under Sierra-Cascade Province, "Quaternary alluvium and glacial debris" should be identified as unconsolidated deposits rather than "rock strata". |
| ㉒ 2-11, C1, P3 | Map Section VI (map addendum) referred to in this sentence does not exist nor are there any areas indicated on the maps indicating liquefaction as a problem. |
| ㉓ 3-60, C2, P2 | Mileposts given for probable slope movements do not correspond with geological hazards shown in the Map Addendum. |
| ㉔ 4-2, C1, P3 | In Section 4.4 the statement of "no significant measures identified" contradicts the engineering and construction measures identified in pages 1-56 to 1-58 as mitigating procedures. |

References

Shannon & Wilson 1978. Geotechnical Investigation Northern Tier Pipeline Company Marine Terminal Facilities Port Angeles, Washington.

In general, the following should be noted with regard to the Geology/Topography/Soils topics:

1) There are many statements or information made in one part of the report that contradict others in some other part of the report.
2) ㉕ The end result of most environmental analysis carries a flavor of "catastrophy" rather than objective evaluation of conditions that might occur realistically. This is particularly true in terms of Soils, and the discussions of seismicity and related liquefaction potentials.
3) Soils are treated too thoroughly and with too much emphasis in comparison to the other earth-related subjects. The soils discussions are also much too theatrical in terms of the potential effects of construction in comparison to natural or existing conditions. Tabular comparisons of existing vs. projected erosion losses in place of lengthy text would be a very significant improvement in this regard.

CONT.

## Ecology (Including Aquatic and Marine Resources, and Terrestrial Vegetation and Wildlife)

The ecology text is generally well organized, presented logically, understandable, and graphically excellent. The descriptive materials are good and generally adequate to assess impacts. The precision of documenting marine resources (i.e., mapping) could be improved and possibly quantified better. The sources for various inventory data, especially data presented in the Map Addendum, are not identified, and the reader cannot double check or search for further clarification without the appropriate citations. An example of this is the mapping of Dungeness Bay as river otter habitat (Map Addendum page 44). Our references indicate that Dungeness Spit and Bay are frequented by harbor seals but not river otter; without a citation we were unable to determine the accuracy of the information.

㉖ The ecology text does have a major weakness, in our opinion, in its treatment of impacts. The magnitude and importance of impacts are not adequately supported by baseline information or by literature concerning potential impacts for a number of topics, including submarine pipeline installation and subsequent turbidity and sedimentation; pipeline installation in terrestrial and freshwater habitats and subsequent erosion and sedimentation impacts; pipeline installation and subsequent disturbance to wildlife; oil spills and subsequent risks to water quality and biota; and abandonment and subsequent impacts on water quality and biota. For example, documentation and explanation of dredging activities that may resuspend heavy trace metals and chlorinated hydrocarbons does not include baseline data to support the presence of such materials in the Port Angeles marine system. The volumes of suspended materials related to dredging are not documented. Similarly, the volumes of eroded materials and sediment created during installation of the pipeline in terrestrial and aquatic habitats are not described in sufficient detail for one to conclude (as is implied in the DES) major nonlocal losses of spawning habitat will occur in almost every stream crossed.

㉗ The sedimentation and erosion impacts predicted do not appear to have considered NTPC-committed (and enforceable) erosion control practices and other pipeline installation techniques (e.g., crossing streams in Washington during the nonspawning and low flow period from mid-June through mid-September).

㉘ It is recommended that documentation of terrestrial habitat losses and disturbance to terrestrial wildlife resulting from pipeline construction be reviewed and clarified. For example, Chapter 2 provides data on bald eagles, which generally occur 1 or more miles from the proposed right-of-way. Chapter 3 provides an impact assessment of bald eagles; statements are made indicating eagles will abandon nests, wintering areas, and feeding habitats because of pipeline construction. Such statements are not supported by baseline data or literature and do not consider the NTPC commitment of environmental inspectors and avoidance of sensitive habitats. In addition, cause and effect relationships between construction activities and critical or significant losses in nest sites for osprey, herons, peregrine falcons, sage grouse, sharptailed grouse, and waterfowl; in elk or deer wintering range; in elk calving habitat; in antelope habitat; in sage grouse dancing grounds; in sharptailed grouse strutting grounds; in grizzly bear habitat; in pheasant habitat; and in fish hatcheries need to be better documented. For example, the interpretation of inventory data in Chapter 2 and in the Map Addendum indicates that many of the areas of concern are not crossed by the right-of-way, are out of the zone of influence (e.g., up-stream), or the species involved have such large home ranges that the area removed is not critical or significant. We believe that the BLM has identified sensitive areas and that the BLM should reevaluate the routing procedures, reclamation procedures, and other mitigation procedures committed to by NTPC that will protect and preserve these sensitive areas. Protective measures not committed to by NTPC should be presented in Chapter 4.

The most important potential impacts of the proposed project could result from oil spills but the impact assessments are not presented in commensurate detail. The discussion could be improved by providing ㉙ information on mode of action, on oil spill probabilities and volumes, and on documentation of water quality or biological impacts. In addition, discussions could be expanded on how oil physically and chemically interacts with water; how oil affects biota physically, physiologically, and behaviorally; and how habitats vary in vulnerability and recovery rates.

Impacts of oil spills are eluded to that are not substantiated, such as ingestion of contaminated prey, magnification of oil through the food chain, and blocking of whale migration. Waterbirds in marine habitats are the most significant group potentially affected but no estimates of potential losses are presented.

㉚ Discussions of oil spill probabilities and volumes do not provide information on the assumptions used to calculate risks and trajectories (for example, the length of time used in the oil spill trajectories for a hypothetical tanker casualty). Submarine pipelines spill probabilities in Table 3.1.7-3 of once in 2.5 years are in conflict with the probability quoted on page 3-25 of once in 161 years.

CONT.

㉛ Pipeline spill analyses include analyses that are not feasible, such as oil spills affecting fish hatcheries that do not use the affected waterway as a water source or that are upstream. Another unfeasible impact evaluation was of a waterfowl loss in North Dakota. The analysis concluded that 25,920 waterfowl per year will be lost should an hypothetical oil spill contaminate a 1/8-mile strip on either side of the right-of-way along 225 miles of wetlands. The assumption of a rupture and spillage along a 225-mile length of piepline is unrealistic. Impact analyses generally do not provide documentation to verify feasibility of impact and assume no mitigation.

㉜ Abandonment impact analyses appear to assume that the total pipeline will eventually be removed without regard to economic feasibility or ecological sensitivity of areas. The removal of the pipeline in submarine areas, river crossings, and other sensitive areas will not likely occur.

## Oil Spills

### Oil Spill Risk Analysis

Although the methodology that has been used by the BLM (OIW 1978a, 1978b) differs somewhat from the oil spill risk analysis performed by NTPC in the EFSEC Application, the results of both studies do, in fact, agree quite well (see attached Tables 1, 2, and 3).

Comments here do not address the issue of bunkering fuel risk analysis since NTPC is currently revising bunkering methods to substitute the use of a small number of T-2 class tankers for the previously proposed large number of barges for the supply of bunker fuel. Since the statistics are influenced strongly by the number of vessel calls, the bunker fuel spill risks will be reduced considerably by this forthcoming revision.

The BLM (OIW) risk analysis is generally based on different historical data bases than those used by NTPC: BLM for the most part used the U.S. Coast Guard's Pollution Incident Reporting System (PIRS) files for tanker spills, while NTPC primarily used worldwide tanker fleet casualty and oil spill statistics. Similarly, the BLM used the PIRS and Gulf of Mexico statistics for pipeline spills, while NTPC used the Department of Transportation (DOT) pipeline spill figures. NTPC favors use of worldwide tanker fleet records and DOT data since they are among the most comprehensive data bases currently available.

The BLM's tanker oil spill risk analysis differs from that of NTPC primarily due to lack of accounting and separating relevant spill types and sizes. The BLM has assumed a probabilistic model (spill rates following a normal distribution, for example) based on a small number of statistical but fixed-exposure variables, such as distance per port call. However, this rate, which characterizes the distributions, contains large deviations from the mean depending on the scatter of the data in the U.S. port system under consideration. Consequently, BLM's results contain large variances. The NTPC, on the other hand, has elected to separate operational (small but frequent) spills from the casualty-related (large but infrequent) spills within the framework of a deterministic model. Furthermore, casualty-related spills have been further separated into two parts: the catastrophic accidents involving total loss of a vessel and the more common casualties that can be represented by average spill volumes. The BLM's risk analysis treatment does not readily allow such distinctions. As a consequence, catastrophic spills (i.e., total vessel losses) would not be predicted realistically (i.e., their predicted frequency of occurrence would be extremely small). In spite of these basic differences in risk analysis methodology and in data base, however, Table 1 shows quite reasonable agreement in tanker spill risk and volumes.

With regard to pipeline oil spills, the use of PIRS and Gulf of Mexico records are expected to pose certain problems. U.S. Coast Guard PIRS files include spills that enter into navigable waters and mostly constitute small operational spills. Thus, they may not adequately describe large leaks or ruptures expected from a new and large pipeline system such as NTPS. Gulf of Mexico experience, on the other hand, involves older pipelines in shallow waters and, therefore, is expected to be quite different in terms of oil spill risks than a deeply buried modern pipeline like NTPS. These factors are reflected in the spill risk comparison shown in Table 2.

Finally, Table 3 displays a comparison of NTPS fire and explosion risks. Since the techniques used in these predictions are quite similar to those used by BLM, the results agree quite well (agreement between the detailed results presented in OIW (1978b) are in fact much better).

In addition, comments relating to specific oil spill information in the DES text include the following.

| Page, Column, Paragraph | Comment |
|---|---|
| ㉝ 3-17, C1, P7 | This paragraph references pipeline spill frequencies to North Bend, but Table 3.1.7-3 is titled "Estimated Frequency of Submarine Pipeline Spills for the Proposed Northern Tier Facility at Port Angeles." This is confusing and needs correction. |

84 CONT

| Page, Column, Paragraph | Comment |
|---|---|
| 3-18, C2, P1 | ㉞ The size of the hypothetical oil spill used for Figures 3.1.7-1 through 3.1.7-6 should be stated. These figures should be preceeded by a spill analysis giving magnitudes as well as frequencies. The placement of the discussion and figures as shown indicates that these results occur each time a spill occurs, regardless of spill size. |
| 3-25, C1, P1 | Estimated oil spill frequency of one spill every 0.0055 years disagrees with Table 3.1.7-3; it presumably should be 0.0055 spills per year (1 in 181 years). |
| 3-28, C2, P1 | The submarine pipelines oil spill frequency should be 0.0054 spills per year, not one spill every 0.0054 years. This disagrees with the 0.0055 probability shown on page 3-25, paragraph 1. |
| 3-79 and 3-85 | The probability of an oil spill occuring in the Quilcene, Dosewallips, Duckabush, Hamma Hamma, or Skokomish Rivers is not given. Also, the probability of a spill of magnitude large enough to do this degree of damage should be given. |

Oil Spill Trajectory Analysis

The physical processes modeled to predict the movement of oil spills are not very different in the BLM (OIW) and NTPC analyses. Both analyses include the effect of wind-induced currents and tidal currents and both grew out of the model developed by the U.S. Coast Guard Oceanographic Unit. ㉟ The biggest difference between the trajectory forecasts appears to be that the BLM forecasts were for a period of five days (page 3-18, C2, P2 states that in Figure 3.1.7-2 Tongue Point would be affected in 60 hours; this time corresponds to about half of the forecast trajectory), while the NTPC forecasts were for no more than 12 hours. If the BLM impact region shown in Figure 3.1.7-3 is reduced by the ratio of forecast times, the results begin to be comparable to those of NTPC.

Several aspects of the BLM trajectory analysis are rather ambiguous, making an accurate comparison of analyses difficult. The following comments refer to statements made on pg. 3-16 of the BLM report. It is stated that oil spill movement is affected by "oceanic pumping" (C1, P6), yet this process is not defined nor referred to again. ㊱ The report states (C2, P1) that the forecast trajectories "do not include the estuarine component," yet several paragraphs later (C2, P7) we find "this model includes...net estuarine flow of about 24 cm/s." This large flow could have an important effect on results. The statement that "oil spill spreading analysis was also incorporated in the model" occurs (C2, P6), yet the very next sentence (C2, P7) states that forecasts were made for "a spill of unspecified size." Since oil spreading is dependent on spill size, these two statements are incompatible. On pg. 3-18 the report argues that, depending on the wind, spills at Port Angeles could endanger either the entire Port Angeles Harbor or the coastline from Port Angeles up to and including Dungeness Spit. This conclusion agrees with NTPC analyses; NTPC added, however, that Dungeness Spit could be affected within 12 hours.

㊲ Without further supporting evidence about the wind and current fields used in BLM model, it is difficult to accept the difference in forecasts shown in Figure 3.1.7-2 and Figure 3.1.7-4 for spills occurring so close to each other. The Port Angeles forecasts shown in Figure 3.1.7-5 and Figure 3.1.7-6 are not in serious disagreement with those of NTPC. The BLM cautions (page 3-18) that the trajectory is sensitive to variations in the currents and wind. We agree and add that because of these variations Admiralty Bay might be affected as well. This possibility is clearly shown in Figures 5.4.2.1-1 and 5.4.2.1-2 of the DES where the submarine pipeline was considered.

In summary, the following points might be made. The most important physical processes affecting oil spill movement are included in both the NTPC and BLM models. The apparent differences are primarily due to the differing times for the forecasts. Several ambiguities in the BLM report make it difficult to infer exactly what approximations were made. The wind and current fields used in the BLM model were not presented and therefore could not be compared with those used by NTPC.

Cultural Resources

The discussion of cultural resources provides a general overview of the project's potential impacts and discusses the possibility that significant materials may be disclosed during project construction. Comments below basically cite the need for clarification of certain statements.

| Page, Column, Paragraph | Comment |
|---|---|
| 2-103 C1, P3 | ㊳ The BLM states that: "it is virtually certain that cultural resources will be discovered along the proposed corridor." Clarification is necessary for distinguishing the corridor and the actual pipeline right-of-way. The area of potential impact will be much smaller than the corridor. |
| 2-104 C1, P2 | ㊴ Mention should be made that state site records were consulted in addition to the National Register. This is only footnoted at the end of the site listings. |
| 2-108 | ㊵ The section on paleontological resources might include a discussion of the relative significance of different types of paleontologic materials. |
| 2-110 | ㊶ Ediz Hook Lighthouse should be included in the listing of historic sites. |
| 3-35 C2, P5 | Archeological beach sites cited as potentially affected should be included in Table 2.1.2.10-1. |
| 3-35, C1, P3 | Shipping associated with the NTPS would not be out of character with the historic context of the old Ediz Hook Lighthouse. The original intent of the early navigation aid was to assist all forms of maritime activities. The presence of tankers and modern berthing facilities could be part of any future interpretive exhibit for the site. |
| 3-36, C1, P7 | Further clarification would be appropriate concerning the relative significance of paleontological materials at Green Point. |
| 3-94, C2, P2 | ㊷ Among the potential indirect impacts listed is the "intrusion of equipment and the line itself across the traditional homelands of Native American populations." Although this could apply to all land in North America, the reference best applies to those properties recognized today as tribal land (e.g., reservations). It is not clear that either direct or indirect impacts would result if the proposed pipeline and related facilities were to include recognized tribal lands. |
| 3-95, C1, P3 | ㊸ The BLM statement that "Unless the final pipeline route were carefully aligned to avoid known sites, they would be directly impacted." implies that sites are known that would be affected. However, the text of this section begins by acknowledging that numerous sites exist along the pipeline route (meaning corridor) but then states that: "...existing site inventory data and the proposed project location and design feature information are presently not adequate for complete and accurate determinations of effects." Clarification of construction phase impacts is needed to indicate that no direct impacts on cultural resources have yet been identified. Only the potential for direct impacts is suggested (see Summary in Section 3.2.10 C2P1). |
| 4-5 | ㊹ Measures 2A and 2B. Measures taken during construction to ensure protection of cultural resources not identified prior to construction include a selective monitoring program. The BLM DES states that if materials are found, work would be required to stop. This is not the most desirable or feasible means of managing the resource if materials are found. Work in an area designated by BLM cultural resource personnel would be suspended until an evaluation of the resource is made. In all likelihood, work would continue at other points further along the pipeline with continued monitoring as necessary. |
| 4-5, C2, P4 | Washington State law requires any person, firm, corporation, or agency to obtain permission from the State Historic Preservation Officer for excavation of cultural resources on public land or from the owners of private land. The state does not have the authority to administer the disposition of cultural resources on privately owned property (Chapter 195, Section 11). |
| 5-7, C2, P1 | ㊺ Indirect impacts on historic structures need qualification. |
| 9-5, C2, P2 | The BLM's Programmatic Memorandum of Agreement with NTPC and the five Northern Tier states should be cited. |

Visual and Recreational Resources

With the exception of the comments below regarding the visual resource analysis, the information and study results reported in the DES are thorough and complete.

| Page, Column, Paragraph | Comment |
|---|---|
| 3-37, C1, P4 | The DES states that: "The panoramic viewshed of Port Angeles Harbor would be radically altered by construction of the tanker berths and support facilities on Ediz Hook. Though not differing in kind, the scale of this activity would visually dominate the existing waterfront industries...". The NTPC aesthetics impact analysis indicates that the viewshed will not be altered (see Figure III-1.19-3 in the NTPC EFSEC Application), that the berthing structures will not conflict in general appearance with those already present, and that the visual character of the tanker unloading facilities will be dominated by the tankers, when they are present, and not by the berthing facilities. (See Figures III-1.19-1, views 5 and 6, and III-2.13-1 in the NTPC EFSEC Application.) |
| 3-37, C1, P6 | ㊻ The DES states that: "Much more significant impacts would occur when the two submarine pipelines were extended through the 120-foot cliff to connect with the tank farm on Green Point... (this activity) would be highly visible to residents and tourists." The NTPC viewshed analysis (Figure III-1.19-3 of the NTPC EFSEC Application) indicates the viewing area from which onsite activity can be seen. A minimum buffer of 65 to 100 feet of existing mature coniferous trees will be maintained around the entire site. The only viewers within a 5-mile radius expected to see construction activity are those immediately adjacent to the site, and three residences are in the open agricultural lands west of the site. Activity associated with the bluff excavation is expected to be visible only from offshore. |
| 3-96, C2, P2 | ㊼ The DES states that: "Of the 433.5 proposed route miles in Washington, 174 miles would parallel or superimpose the BPA right-of-way." The NTPC analyses indicate that total powerline right-of-way followed within the State of Washington is 176.5 miles out of a total route length of 435 miles. The route as proposed will also follow 23.3 miles of existing pipeline right-of-way and 21.8 miles of existing railroad right-of-way, for a total of 221.0 miles of existing cleared right-of-way, or 51% of the total route length in Washington. |

General

Many of the visual evaluations are purely subjective and may in fact be misleading. In the baseline visual analysis, for instance, reference is made to the harbor area as having a very high level of visual quality (A or A/B), largely due to the "novelty" of having pulp and paper mills, harbor traffic, etc. Yet, they say in the impact analysis that the operation of the unloading facilities will have a negative impact on visual quality. If one were consistent, it could be argued that an unloading dock may also represent a "novelty" aspect.

Land Use

The DES adequately addresses land issues related to the NTPP. Inconsistencies with the NTPC EFSEC Application and other comments are presented below.

| Page, Column, Paragraph | Comment |
|---|---|
| 2-60, C2, P3 | ㊽ Discussion of state and local government zoning and comprehensive plans should indicate that the text of Clallam County's Zoning Ordinance was declared void by the Washington Supreme Court. |
| 2-113 | Source for Table 2.1.2.10-1 should be NTPC. The heading in the first column of the table should read "All Land Uses." Also, statements (C1, P4) regarding urban and residential land uses along the pipeline route are not consistent with the above table, which shows that only 3.0 miles of urban/built-up land are traversed by the pipeline route in Washington. |
| 2-119, C2, P2 | ㊾ The discussion of land should also indicate how much prime farmland there is in each state. Then prime farmland in right-of-way versus elsewhere in state can be compared to indicate the effect of the proposed pipeline. |
| 3-40, C2, P2 | The size of the onshore storage facilities site should be 243 acres. |
| 3-2 | There are numerous comments made throughout the discussion of pipeline system impacts relating to impacts of access roads. In all but the most rough terrain, access will be obtained by existing roads and the pipeline right-of-way. |
| 3-106, C1, P2 | ㊿ How large is the assumed spill on agricultural lands? The frequency of one spill per 0.8 year is provided but no spill size is indicated. The same comment applies to discussion of impacts on rangeland/shrubland and forest/woodland. |
| 4-5, C2, P7 and<br>4-8, C1, P3 | (51) In the NTPC EFSEC Application, NTPC included a number of committed mitigation measures that should be described in the DES. These include relocation of the Puget Sound Pilots Association and the recreational boating facilities based on Ediz Hook, and making minor pipeline route changes to minimize impacts on existing and planned residential areas and subdivision. |
| 5-8 | (52) Table 5.1.12-1 is inaccurate. The NTPC has committed to relocating the pilot station and recreational boating activities on Ediz Hook. |

Transportation and Utility Networks

Certain discrepancies are noted between the DES and the NTPC EFSEC Application. The transportation analysis does not fully follow from data presented in the DES and certain assumptions are not specified. The discussion of electric energy impacts should be revised to describe implications of the power requirements of the pipeline in the event of an operating shortage (versus the current planning shortage) on the BPA system. Specific comments are noted below.

| Page, Column, Paragraph | Comment |
|---|---|
| 2-32, C1, P6 | (53) The relevance of summer weekend peak traffic to the proposed action should be stated either in this section or in the impact section. |
| 2-36 | (54) Table 2.1.1.13-5 does not indicate dates (years) for the forecasted loads. |
| 2-162, C2, P9 | (55) The discussion of future power availability should indicate implications of pending federal legislation that would require BPA to continue to provide power to meet the load growth of its preference customers. |
| 3-42, C1, P4 | (56) The NTPC EFSEC Application indicates that the submarine pipeline construction is to occur between December 1979 and February 1980 (not June through September 1980). |
| 3-42, C1, P5 | Should be 933,000 bpd throughput. |
| 3-42, C2, P1 | Should be 395 (not 390) tanker calls per year at ultimate throughput. Also, it is not possible to verify the stated 34% and 44% increase in commercial traffic from data given in Table 2.1.1.13-1 without further explanation. Similar explanation for the derivation of the stated 145% and 188% increase in large vessel traffic is needed. |
| 3-43, C1, P2 | (57) The maximum number of construction personnel (90) would be required for only the two peak months of tanker berthing facilities construction, not for "most of the construction period." The number of trucks (round trips) estimated by NTPC for the second through fourth quarter of construction was about 16 per day, an average figure that assumes all deliveries to be concentrated in the normal Monday through Friday (five-day) work week. If deliveries are spread over six days, the figure is even lower. |
| 3-43, C1, P3 | (58) It is not clear what is meant by a 75/25 east-west split in traffic. If this sentence is intended to imply that 75% of construction worker and truck trips would originate west of the Green Point site, then the basis for this assumption should be stated. |
| 3-43, C1, P4 | (59) The peak construction months for the marine terminal based on estimates presented in the NTPC EFSEC Application are May and June 1980 (not February and March 1980 as is stated). |
|  | The figure of 420 workers commuting through Port Angeles (for the peak marine terminal construction months) is close to 75% of the average number of construction workers (626) estimated for May and June 1980. The validity of the BLM figure, therefore, depends on the reasonableness of the inferred assumption that 75% of construction related trips originate west of Green Point. |

84 CONT

| | | |
|---|---|---|
| (59) | | The average number of trucks (round trips) would not exceed 15 to 20 per day based on NTPC estimates. The BLM figure of 90 trucks per day overestimates the actual number by a factor of five or six.<br>Construction related traffic would decrease to about 40% to 50% of the peak value after the peak two months, not 20% to 60%. |

| | Page, Column, Paragraph | Comment |
|---|---|---|
| (60) | 3-46, C1, P5 | Data in the text and in Table 3.1.13-3 do not agree with data in the NTPC EFSEC Application. The DES text describes forecasted loads without specifying the year (1981 or 1985). Furthermore, data in the NTPC EFSEC Application indicate that the City of Port Angeles will have an allocation from BPA of 93 average MW and that the Clallam County PUD will have an allocation of 61 average MW. According to data in Table 3.1.13-3, demand in 1985 for the City Light Department would be 108.6 average MW, or 15.6 MW more than the allocation (not 19 MW as noted in the text).<br>The 1985 forecasted average load for the county PUD of 132.5 MW does not agree with the 71.7 MW figure in the NTPC EFSEC Application. (If Table 3.1.13-3 were correct, it would mean that the county PUD's load will grow from 58 to 132.5 average MW from 1981 to 1985, an increase of 128%.) Using the 71.7 MW figure, the county's BPA allocation would be 10.7 average MW less than average load, not 7.5 MW as noted in the text. |
| (61) | 3-46, C2, P1 | The Official Statement prepared by WPPSS indicates that power available from nuclear units 4 and 5 will be about 6 MW per unit (total 12 MW) to the city and 17 MW per unit (total 34 MW) to the county (Official Statement of WPPSS, 23 May 1978). Thus, the two utilities will have twice the amount of energy available as indicated in the DES.<br>The changes suggested in the above comments are summarized in the following table. |

Page, Column, Paragraph

Comment

| Serving Utility | 1985 Average Load (MW) | BPA Allocation Effective 1 July 1983 (average MW) | Shortfall Without Additional Power Supplies (average MW) |
|---|---|---|---|
| Port Angeles City Light Dept. | 108.6 | 93 | 15.6 |
| Clallam County PUD | 71.7 | 61 | 10.7 |

The language regarding the extent of power shortages based on the above forecasts should be revised to reflect the corrections. In addition, forecasted energy dates of WPPSS units 4 and 5 should be considered. (See the most most recent PNUCC West Group Forecast and page 15 of the WPPSS Official Statement to determine availability of the additional power. These documents suggest that units 4 and 5 will not be fully operational (generating at full capacity) until 1986 and 1987, respectively).

| | | |
|---|---|---|
| (62) | 3-46, C2, P3 | Statements made in the last paragraph of the Operation Phase discussion are misleading. While the available forecasts certainly support a planning shortage, allocation procedures in the event of an operating shortage (when power resources are inadequate to meet actual demand at a given time) suggest that NTPC facilities will not adversely affect the availability of power in Clallam County since BPA will be able to curtail sales to nonfirm loads (i.e., to the direct service industries) to avoid curtailing sales to its firm (preference) customers. There are certain additional steps that can be taken by both BPA and the Governor of Washington to avoid or to minimize such curtailments. Discussion with BPA could help to clarify and to expand the analysis of NTPC's impacts on power availability. |

| | Page, Column, Paragraph | Comment |
|---|---|---|
| (63) | 3-109, C2, P2 | It is not at all clear how an inspection flight every two weeks can have a statistically significant impact on the collision risk at an airport with 25,000 or more operations annually. Even if each "penetration" by an inspection flight is considered as equivalent to adding one "operation," this amounts to no more than 0.1% of the total at any of these four airports. |

| | | |
|---|---|---|
| (64) | 4-6 to 4-8 (Section 4.13) | In Section III-5.3.17 of the NTPC EFSEC Application, NTPC included committed mitigation measures that should also be included in the DES. These concern electric energy conservation.<br>To define potential mitigation measures, NTPC is examining alternative approaches to obtaining electric power or driving pump stations with other sources of energy where power may not be readily available from local utilities. |

Social and Economic Conditions

There are some major problems noted with the analysis of impacts, particularly with respect to derivation of figures, assumptions, and the general methodology of the analysis. Data presented in Chapter 3 of the DES do not agree with the results of analyses presented in the NTPC EFSEC Application. Specific comments and questions are noted below.

| | Page, Column, Paragraph | Comment |
|---|---|---|
| (65) | 2-41, C2, P1 | Clallam County total employment in 1976 was 16,450 and unemployment was 9.8%. |
| (66) | 2-42, C2, P2 | The Washington Department of Social and Health Services estimates that there are nearly 1,000 transient units in Clallam County, not 800. (See Table 2.1.1.15-1 on page 2-141.)<br>What is the data source for 1% rental vacancy estimate? |
| (67) | 3-49, C2, P3 | Additional explanation is necessary to verify the conclusions of the DES. For example, how were population estimates derived? What assumptions were used with respect to the percentage of nonlocal construction workers who would in-migrate to the county? What multipliers were used to establish indirect and induced populations?<br>How can the June 1981 population be 100 and the July 1980 population be 100 when there will be a total of only 18 construction workers in each month? |
| (68) | 3-50, C1, P1 | How were population estimates derived? What multipliers were used? The NTPC estimate of operations period total population growth (direct, indirect and induced) is 233, not 307 (see the NTPC EFSEC Application). |
| (69) | 3-50, C1, P3 | The average work force in Clallam County over the 22-month construction period is 217 workers not 450. The peak is 670 not 755. |

| | Page, Column, Paragraph | Comment |
|---|---|---|
| | | What is the basis for the statement that: "The initial phase would employ at peak about 160 local workers on the construction work force..."? What local-nonlocal distribution was assumed? |
| (70) | 3-52, C2, P6 | The basis for the estimate that 200 children would be added to the area's school population is not provided. |
| | 3-53, C1, P2 | The per pupil expenditures cited, as furnished by the Port Angeles School District, are about 50% higher than the 1976-1977 data furnished by the Washington Superintendent of Public Instruction and included in the NTPC EFSEC Application. |
| (71) | 3-53, C2, P1 | No literature reference is provided to document the suggested increase in misdemeanor as a result of NTPS construction. |
| (72) | 3-53, C2, P6 | The local newspaper is not an authoritative source on the question of responsibility for fire protection. Recent data received by NTPC from the city suggest the [illegible] water line on Ediz Hook likely has sufficient capacity to meet NTPC construction-related fire fighting needs. |
| (73) | 3-54, C1, P2 | It should be noted that the city fire department would not have primary responsibility for fire safety and fire fighting in conjunction with the NTPC facilities. Fire protection at petroleum facilities is historically provided by the firms that operate the facilities since these firms have the specialized expertise, equipment, and trained staff to deal with such fire protection needs. The NTPC EFSEC Application describes in detail fire protection systems to be provided by NTPC. |

| | Page, Column, Paragraph | Comment |
|---|---|---|
| (74) | 3-117, C2, P2 | What is the basis for mainline pipeline worker estimates? Even for all other project components, |
| (75) | 3-119, C2, P3 | what is the basis for assuming that "for counties with less than 35,000 population, 10% of the in-state work force was estimated to be local and that for counties with 100,000 population, 50% was estimated to be local"? |

| | | |
|---|---|---|
| (76) | 3-120 | The construction work force estimates by month are totally inconsistent with those provided in the NTPC EFSEC Application. This effects the entire social and economic impact analysis. |
| | 3-122 (Table 3.2.15-3) | Construction work force estimates by county and by time interval are totally inconsistent with those provided in the NTPC EFSEC Application. For instance, how could there be 125 construction workers in King County from August 1980 through November 1980 when the only activity in the county during this period will be the construction of a pump station. During this period, the pump station will require an average of less than 42 workers. |
| (77) | 3-123 (Table 3.2.15-4) | What employment multipliers were used? What was the basis for selecting these particular multipliers? |
| (78) | 3-124 (Table 3.2.15-6) | Total construction costs in Clallam County are estimated to be $130,515,000 not $117,542,000. All other construction cost estimates by county are also inconsistent with estimates in the NTPC EFSEC Application. |

| | Page, Column, Paragraph | Comment |
|---|---|---|
| (79) | 4-8 (Section 4.15) | In Section III-5.3.15 of the NTPC EFSEC Application, NTPC specified additional committed mitigation measures that should be included in the DES. The following actions are specified: provision of a fully equipped and manned fireboat in Port Angeles Harbor and provision of a fire truck at the onshore storage facilities (in addition to other built-in fire protection systems), an independent third-party evaluation of the firefighting systems and procedures, and an analysis of any possible effects on fire insurance rates.<br>In addition, as a potential mitigation measure, NTPC has indicated its willingness to consider making prepayments of property taxes under certain conditions. These conditions are also noted in Section III-5.3.15 of the NTPC EFSEC Application. |
| (80) | 5-11 | The number of 154 new students in Table 5.1.15-1 does not agree with the text of Chapter 3. Specifically see page 3-52, which indicates 200 students would be added during construction. |
| (81) | 6-2, C1, P2 | These two sentences, taken together, appear to cast a very negative light on the entire marine terminal component that may be unwarranted in view of the impact chapters of the DES. It is not at all clear how the "short-term commitment of the area's resources" would impede maintenance and enhancement of area resources in the long term. If oil spill risks are what the authors have in mind, then clearly this sentence is a nonsequitur. More serious, however, is the second statement, which refers to a perception (presumably by the local |

| Page, Column, Paragraph | Comment |
|---|---|
| | populace and/or environmental activists) that the project would have "potentially long-term risks to health (and) safety..." This statement, taken as it stands without further qualification (and in the context suggested by the statement immediately preceding it) could be inferred by the reader as meaning that the DES authors are the ones making this blanket judgment. |

Alternatives to the Proposed Action

Some alternative projects considered by BLM differ from those considered by NTPC, and the relative emphasis and level of detail presented for such projects as well as for alternative port sites and pipeline route segments differ. However, the conclusions reached by BLM are fairly consistent with those reached by NTPC. Some specific comments on the text follow.

| | Page, Column, Paragraph | Comment |
|---|---|---|
| (82) | 8-4, C1, P2 | In the description of the Stampede Pass route alternative, it should be noted that this route would have crossed 1.5 miles of the Cedar River watershed (in addition to the 28 miles crossing the Green River watershed mentioned in the DES), which furnishes water to the City of Seattle. |
| (83) | 8-5, C1, P5 | It would be appropriate to state for the Alaska-Alberta Pipeline alternative that air pollution impacts would be experienced at Haines and Skagway. |

| | | |
|---|---|---|
| (84) | 8-6, C2, P1 | The statement that the Mid-Continent Pipeline System has a capability of expansion of 875,000 bpd should be clarified. This expansion capability does not represent a total potential increase in capacity from the Gulf Coast into the Northern Tier states because it represents a sum of expansion capabilities for a number of pipeline systems, many of which do not originate on the Gulf Coast and some of which are product pipelines that could transport crude oil only at the expense of product shipments. It should also be noted that the Mid-Continent Pipeline System is not capable of supplying any of the refineries in the Northern Tier states west of Minnesota. |
| (85) | 8-10, C2, P4 | The discussion of existing $SO_2$ air quality at Cherry Point should be clarified. Why are the model results likely to be overestimates? What do the model results mean? |

| | Page, Column, Paragraph | Comment |
|---|---|---|
| (85) a | 8-36, C1, P6 and 8-83, C2, P3 | The traffic assessment performed by NTPC for the Low Point alternative concluded that while the *relative* peak hour construction impact on S.R. 112 west of Port Angeles would be significant, the roadway would still be operating at only about 60% capacity, implying a level of service A or B. |
| (86) | 8-44, C2, P3 | When referring to the greater risk of at-berth spills for single point moorings at Low Point and Freshwater Bay, it should also be noted that spills would also be much more difficult to contain and clean up at an offshore location (because of wind, wave, and current conditions) compared to a fixed berth site in Port Angeles Harbor. |
| (87) | 8-98, C1, P3 | The statement that: "Canada would benefit by either of the proposals (Foothills) as it would permit access of Canadian markets to foreign crude oil, if the need should develop in the future" should be expanded to note that the Northern Tier Pipeline System, through its connection to the Lakehead/Interprovincial System at Clearbrook, would also provide eastern Canada with access to foreign crude through a west coast port. |
| (88) | 8-105, C1, P5 | With regard to the Trans-Mountain Reversal project, the statement that: "The 180,000 bpd (average) pumped to Edmonton would be distributed to deficient areas in the Northern Tier and Midwest states through the same common-carrier pipelines that previously handled the Canadian deliveries" is only partially true since oil cannot move to Billings, Montana, refineries from Edmonton over existing pipelines. The existing pipeline system (Texaco) south of Edmonton flows north and, thus, |

| | Page, Column, Paragraph | Comment |
|---|---|---|
| | | oil cannot move south to the Billings refineries without the construction of a new pipeline link to the Rangeland System, which does flow south. |
| (89) | 8-113, C2, P2 | See previous comment on statement made on page 8-6 regarding expansion capability of 875,000 bpd for the Mid-Continent System. The statement that: "Most of these increases, 530,000 bpd, would be from the Gulf Coast" should be clarified. This additional capacity of 530,000 bpd would be from the Gulf Coast to Cushing, Oklahoma, which would not solve crude oil shortfalls in the Northern Tier states. |
| (90) | 8-113, C2, P4 | The following comments relate to the discussion of the major new pipelines being proposed. There are five planned projects listed, not six. The statement that: "If all lines were built, the total maximum increase in capacity would be about 3,490,000 bpd." is misleading because all the projects listed do not represent additional pipeline capacity into the upper Midwest and Northern Tier states. SOHIO and Four Corners represent additional capacity into the Gulf Coast area, not the upper Midwest and Northern Tier states. Northern Pipeline must depend on other pipelines or barges for supplying its line out of Wood River. Therefore, the planned capacities of these lines cannot be summed and represented as an increase in total pipeline capacity for supplying the Northern Tier and upper Midwest states. |
| (91) | 8-114, C2, P3 | The statement that: "Following shipment to Gulf Coast Ports, the Alaskan crude oil would be distributed to the Northern Tier states through the Mid-Continent Pipeline System" is misleading because Mid-Continent pipelines cannot supply refineries in the Northern Tier states [illegible] of Minnesota. |

MUCKLESHOOT INDIAN TRIBE
RESOLUTION NO. 79-59-5

WHEREAS, the Muckleshoot Indian Tribal Council is the governing body of the Muckleshoot Indian Tribe of the Northwest, by authority of the Constitution and By-Laws of the Muckleshoot Indian Tribe as approved May 13, 1936, by the Secretary of Interior, and,

WHEREAS, the Muckleshoot Indian Tribe of the Northwest have by reason of the Boldt Decision in United States vs. Washington, recognized usual and accustomed fishing grounds stations guaranteed by the Treaty of Point Elliott in the waters of Puget Sound, and,

WHEREAS, the Northern Tier Pipeline Company is proposing to construct an oil off loading facility at Port Angeles, Washington and oil transportation pipeline around or through the waters of Puget Sound, and,

WHEREAS, this pipeline would cross three lobes of Puget Sound or more than 40 major rivers and streams draining into Puget Sound, and,

WHEREAS, a recent Department of Energy Study casts serious doubts on the economic necessity of this proposal, and,

WHEREAS, this pipeline carries with it the risk of oil spillage into water flowing into Puget Sound or directly into the main waters themselves, and,

WHEREAS, the Puget Sound salmon production alone carries present annual processed value of $69,500,000, and,

WHEREAS, many treaty and non-treaty fishermen rely on this resource for thier livelihood, and,

WHEREAS, any spillage of oil into the waters of Puget Sound or its tributary rivers and streams would cause serious and irrepairable damage to the resource, and,

WHEREAS, many more millions of dollars of commercial fish and shellfish residing in Puget Sound would also be seriously damaged, and,

MUCKLESHOOT INDIAN TRIBE
RESOLUTION NO. [illegible]

WHEREAS, the quality of life in Washington State depends heavily on the rivers, beaches and waters of Puget Sound and,

WHEREAS, these waters are sheltered and, as such, any damage to these waters and the resources dependent on them would be extremely slow in recovering from a major oil spill, if recovery occurred at all, and,

NOW, THEREFORE BE IT RESOLVED, that the Muckleshoot Indian Tribe of the Northwest is of the opinion that Northern Tier Pipeline Company's proposed Crude Oil Transport system would be damaging and detrimental to the public interest and imperils the fisheries resources of the Muckleshoot Tribe of the Northwest and, consequently, is totally unacceptable as proposed, and,

AND BE IT FURTHER RESOLVED, that the Muckleshoot Tribe of the Northwest strongly urges consideration of alternative proposals which do not effect the waters of Puget Sound.

CERTIFICATION

As Secretary of the Muckleshoot Tribal Council, I hereby certify that the above resolution was duly adopted at a regular/~~special~~ meeting of the Muckleshoot Indian Tribe on the 26 day of March, 1979, held on the Muckleshoot Indian Reservation, Auburn, Washington, at which a quorum was present, by a vote of 45 for 0 against 0 abstentions.

U.S. ENVIRONMENTAL PROTECTION AGENCY
REGION X
1200 SIXTH AVENUE
SEATTLE, WASHINGTON 98101

REPLY TO ATTN OF: M/S 443

[illegible] 1979

Al Leonard, Project Manager
Northern Tier Project Office
Bureau of Land Management
700 N.E. Multnomah, Suite 1250
Portland, Oregon 97232

Dear Mr. Leonard:

We have completed our review of BLM's draft environmental impact statement (DEIS) on the Northern Tier Pipeline Company's proposed Crude Oil Transportation System. We have concluded, based upon this review as well as our review of supporting technical studies and citizen testimony at public hearings, that the DEIS is seriously inadequate. We have also concluded that the DEIS, when viewed within the context provided by the U.S. Department of Energy draft report entitled "Petroleum Supply Alternatives for the Northern Tier and Inland States Through the Year 2000", does not yet provide the type of information or analysis necessary to provide reasonable bases for comparing the alternative proposed crude oil transportation systems as required by Title V of the Public Utility Regulatory Policies Act of 1978 (Public Law 95-617, hereinafter referred to as "Title V").

Our major concerns with regard to the technical content of the DEIS are outlined below. The attachments to this letter provide detailed comments on the DEIS and on the analyses which we believe should be performed in order for the final environmental impact statement (FEIS) to provide a useful basis for Federal agency recommendations with regard to which proposed transportation system, if any, should be approved by the President and Congress.

Need for a Transportation System

① Our comments on the U.S. Department of Energy draft report, mentioned above, will be provided to the Department of Energy (DOE) and your office by the April 20, 1979 comment deadline. We believe that the DOE study, in its final form, will determine, in part, what systems and system capacities should be analyzed for the FEIS. In particular, if DOE confirms its estimate of crude oil transportation system capacity needs then the Northern Tier proposal would have to be evaluated at the probable throughput rate of 200,000-400,000 barrels per day by the year 2000 (plus any additional throughput to serve Puget Sound refineries).

Air Quality

As you know, we have serious concerns about the technical adequacy and validity of the technical studies that were performed for BLM to evaluate the air quality effects of the Northern Tier proposal. Our comments on the technical study, which was performed by Science Applications, Incorporated (SAI), were sent on December 1, 1978. We are in the process of completing our review of SAI's response to those comments and have identified the following concerns to date:

② 1. The DEIS's discussion of air quality effects and the numerical estimates of these effects (in the DEIS) do not track with or correlate with the numerical estimates in the SAI study, even though the DEIS cites the SAI study as the principal source document. In the absence of an explanation the DEIS analysis therefore appears to be unsupported.

2. The SAI response tends to underestimate the degree of uncertainty in the impact predictions which result from using the selected Port Angeles meteorological data.

3. The SAI response appears to underestimate pollutant emissions from the terminal and onshore storage facilities.

③ 4. The use of Port Angeles meteorological data for the analysis of air quality effects at the Low Point site appears to be questionable.

④ 5. Terrain impact problems for tanker emission plumes need to be treated in substantially more depth by the analysis.

Additional detailed comments regarding the DEIS's air quality discussion are contained in Attachment I. We will provide a detailed response to the SAI response to our December 1 comments after we have had the opportunity to discuss it with your staff and SAI's technical staff.

Water Quality

⑤ The DEIS's analysis and discussion of water quality impacts is generic and qualitative. It needs to be revised so that it specifies whether potentially affected water bodies currently meet the applicable water quality standards. If there are current standards violations, the causes of these violations should be identified, where possible. The DEIS should then evaluate whether terminal/pipeline construction and operation would result in any additional standards violations or in the aggravation of existing violations.

It should, within that analysis, evaluate the effects on water quality of the treated site runoff discharges from the terminal area and the onshore storage facility, which are likely to contain small concentrations of crude oil as well as other contaminants.

The discussion of oil spill impacts on aquatic resources is qualitative and generic; that is, currently it does not quantify the possible and probable impacts of oil spills at the terminal site, enroute to it, or along the pipeline route. ⑥ Additionally, the discussion of the resources potentially affected apparently undervalues some of these resources. For example, testimony by officials of the British Columbia fishermen's labor union indicates that the Canadian commercial fisheries were undervalued by an order of magnitude. On the latter problem, we recommend that the estimates be verified and revised where necessary. It would also be useful if the FEIS explained how the value estimates were derived (for example how did the Washington State Department of Fisheries develop its estimates). ⑦ On the former problem, we believe that a quantitative comparison of the potential impacts of oil spills associated with the alternative port sites and the alternative transportation systems is essential.

Such a quantitative analysis would, within the limits imposed by the state of our knowledge with regard to the movement of spilled oil and the fate and effects of oil in marine and freshwater environments, estimate the losses which would result from oil spills of different sizes at different locations. Among the spill sizes examined should be the large magnitude spill which would result from the total loss of a Very Large Crude Carrier (VLCC) such as occurred off the coast of France in the Amoco Cadiz sinking.

CONT

Additional detailed comments regarding the DEIS's water quality impact analysis and technical problems with the oil spill risk analysis are contained in Attachment I.

Drinking Water Quality

⑧ Possible effects of the crude oil pipeline on drinking water quality are given a rather brief discussion in the DEIS. Given that most of the streams which the pipeline route crosses on the Olympic Peninsula serve as public water supplies, the FEIS should locate these streams and their watersheds on the detailed maps in the map addendum. It should quantify the possible effects of an oil spill on each potentially affected water supply.

⑨ The Spokane Valley-Rathdrum Prairie Aquifer is also given a very brief mention in the DEIS. As you know, this aquifer has been designated a sole source under Section 1424(e) of the Safe Drinking Water Act. Although the pipeline route does not pass directly over the aquifer, it does pass through a major portion of the stream flow source zone, (that area which recharges the aquifer), and crosses streams which make significant contributions to aquifer recharge. A much more detailed discussion of the aquifer, a quantification of possible impacts, and a discussion of additional possible mitigation measures are needed for the FEIS. Attachment I contains more detailed guidance with regard to the information which should be included in the FEIS.

Secondary Development Impacts

⑩ The DEIS assumes that the construction and operation of a crude oil receiving terminal in Washington State will not lead to secondary development in the petrochemical/petroleum refining industry. It therefore does not analyze the environmental impacts of such development in the vicinity of possible terminals. This assumption apparently conflicts with the record of the industry to date.

The Department of Transportation, in its analysis of possible secondary development associated with a proposed deep water crude oil receiving terminal in Louisiana, found that the correlation coefficient between crude oil supply (terminal location) and petrochemical development was +.89. When these findings are combined with the findings in recent Department of Energy studies that Washington State's refining capacity will need to be expanded by 150,000 barrels per day by the year 2000, it is reasonable to assume that refinery development would accompany/follow the establishment of a new crude oil receiving terminal.

Therefore, the FEIS should analyze in some detail the environmental effects of probable secondary petrochemical industry development at Northern Tier's alternative port sites. ⑪ A similar analysis would need to be performed for the Low Point terminal site proposed by the Trans-Mountain Pipeline Company.

Title V Alternatives Analysis

⑫ The issues which merit attention and the level of detail appropriate for the analysis of each of the main alternatives being considered under Title V are essentially the same as were and are necessary for the Northern Tier proposal. That analysis should be based upon complete and accurate descriptions of the proposed systems (as you know the material in the DEIS is not accurate) and whatever baseline environmental data can be obtained within the time available.

Although Attachment II details our concerns with regard to the DEIS's analysis of alternatives in Chapter 8 and our desires for the FEIS, there are some issues, common to a number of the alternatives, which merit mention here. These "issues" include:

⑬ 1. The ability of the alternative systems to meet the "need" identified in the DOE studies (alternatives that depend on connections to existing systems should be checked to ensure that spare pipeline capacity is available).

⑭ 2. The comparative values of the marine resources exposed to the risk of an oil spill.

⑮ 3. Potable water supplies exposed to the risk of an oil spill.

⑯ 4. A quantification of the damages which could result from a major oil spill.

⑰ 5. The effects of the proposal on ambient air quality in the vicinity of the terminal site.

⑱ 6. Populations exposed to the risk of a terminal fire or explosion and the ability of local public safety personnel to respond to such an event.

⑲ 7. The effects of pipeline construction on the physical environment and aquatic biota as well as the effects of pipeline operation on fisheries.

For each of these issues the analysis and discussion should be quantitative enough to support ranking the alternative systems being considered based upon environmental protection and enhancement criteria.

86 CONT

Conclusions

As we noted at the beginning of this letter, we believe that the DEIS is seriously inadequate. At the present time, we cannot determine which alternative system, if any, is environmentally preferable, as required by the new CEQ regulations. Similarly, we cannot determine whether the proposed project (Northern Tier) is environmentally acceptable.

As you know, in making the above determination, we normally assign a rating to the proposed action and to the DEIS as a means of carrying out our duties under Section 309 of the Clean Air Act, as amended. However, due to the gaps in the DEIS we are unable to assign one of the normal proposed action ratings (LO: lack of objections; ER: environmental reservations; or EU: environmentally unacceptable). We therefore must give the DEIS a rating of "3" (inadequate). This rating will appear in the Federal Register in accordance with our responsibility to inform the public of our views on proposed Federal actions, under the above referenced section of the Clean Air Act.

Under normal circumstances we would recommend that a revised draft environmental impact statement be prepared and circulated for public comment prior to the preparation of the FEIS, in situations like this one. However, we recognize that Congress, with the enactment of Title V of Public Law 95-617, has called for an expeditious decision making process with regard to crude oil transportation systems serving the Northern Tier states.

We believe that the current schedule for carrying out the requirements of Title V is extremely tight and may impede BLM's efforts to produce a credible FEIS which can serve as one of the major bases for the decision on Northern Tier crude oil transportation systems. We strongly recommend that the Department of the Interior reconsider its Title V review schedule after evaluating the comments received on the DEIS and estimating the amount of time and resources that will be needed to respond credibly to those comments. It is our considered judgement that an extension of the review schedule is almost mandatory if the FEIS and the Report to the President (called for by Title V) are to properly address the substantive decision criteria specified in the statute.

We have appreciated the opportunity to participate in the EIS team's efforts to date and would be glad to explain our concerns in more detail where that would help you in the preparation of the FEIS. In order to arrange any further discussions which you deem necessary, your staff should contact Daniel Steinborn, the coordinator of EPA's participation in the Title V review, at (FTS) 399-1285 or (206) 442-1285.

Sincerely,

Donald P. Dubois
Regional Administrator

ATTACHMENT I

U.S. Environmental Protection Agency
Detailed Comments re BLM's Crude Oil
Transportation Systems DEIS

Chapter 1* - Description of the Proposed Action

Major Items

(20) Pages 44-60. The statement indicates that the pipeline will be covered with a minimum of three feet of soil. For stream crossings, such as the Coeur d'Alene River, the pipe thickness is to be increased and the line will be buried below the stream bed scour level. We recommend that the applicant, if the project is approved, be required to use concrete coated pipe in all streams which contain or support fishery resources and in all streams which serve or affect public water supplies. Additionally, inspection of underwater stream crossings should not be limited to navigable waterways. For those streams which are within the streamflow source zone of the Spokane Valley-Rathdrum Prairie Aquifer the on-the-ground inspection interval should be no more than one to two years. A similar inspection interval should be applied for any stream crossings that are upstream of water supply intakes.

(21) The actual inspection process should be described. Additionally, the means by which water supply operators and other appropriate response agencies will be notified of pipeline-related oil spills should be discussed.

(22) The terminal at Clearbrook, Minnesota would be operated by the Lakehead Pipeline Company. According to our Region 5 personnel this company's operating record has not been particularly good (it has experienced numerous spills). The Final Environmental Impact Statement (FEIS hereafter) should discuss this performance record and indicate what improvements Lakehead could and would make in its operating procedures.

CONT

Minor Items:

(23) Page 5. Table 1.3-1 should note EPA's review of Spill Prevention, Countermeasures, and Control (SPCC) plans under the Federal Water Pollution Control Act Amendments of 1972 as amended by the Clean Water Act of 1977. It should also note our review required by Section 1424 of the Safe Drinking Water Act due to the sole source designation of the Spokane Valley-Rathdrum Prairie aquifer.

(24) Page 11. The discussion of submarine pipeline inspection should describe the ability of the infra-red monitoring system to detect leaks in rough water conditions.

*Note: The chapter number portion of each page number is omitted.

ATTACHMENT I - Page 2

(25) Page 10. One fire boat appears to be totally inadequate. The explosion of the tanker *Sansanea* in Los Angeles harbor required the use of about six fire boats. Location of the fire boats at a safe distance would be required in order to prevent their being destroyed by an explosion.

(26) Page 13. The volume of the runoff water discharge should be estimated (for the onshore storage facility as well as the port facility). If the crude oil contains 2 to 3% water this could be a substantial discharge and, even with the use of oil-water separators, could result in a significant discharge of oil to the receiving water body.

(27) Page 7. We understand that the tanker fleet scenario is extrapolated from data provided by Northern Tier for a throughput of 709,000 barrels per day. A linear extrapolation may be inappropriate due to the constraints imposed by the availability of Jones Act tankers. The ultimate fate of SOHIO's proposed transportation system would affect tanker availability. A scenario should also be developed for whatever throughput is determined to be necessary by the Department of Energy needs study.

(28) Page 18. The pipeline operating pressure should be specified. The margin of safety provided by the maximum yield strength for the pipe should be shown.

(29) Page 35. Although the Clearbrook terminal facilities are not being constructed by the applicant, they are necessary for the system to operate and therefore must be evaluated by this EIS. Similarly, a proposed connecting pipeline from Clearbrook to East St. Louis, Illinois should be evaluated.

(30) Page 40. What steps will be taken to ensure that we do not repeat the weld inspection problems which were experienced with the Alyeska Pipeline?

(31) Page 46. During stream crossing construction the applicant proposes to store excavated material on the stream bottom adjacent to the trench. Such a practice would cause unnecessary sedimentation and damage to downstream fishery resources. EPA would not concur in any Corps of Engineers permit which allowed it. Upland storage or storage on barges should be required.

(32) Lining the trench with bentonite clay in marshy areas could cut off flow within a wetland area and cause portions of it to dry up. A flow maintenance system may be required to preserve the wetlands.

(33) Page 47. Discharges of hydrostatic test water would require an NPDES discharge permit under Section 402 of the Federal Water Pollution Control Act Amendments of 1972 as amended by the Clean Water Act of 1977.

ATTACHMENT I - Page 3

(34) Page 53. The draft DOE report indicates that DOE did not do an independent cost estimate, but took the applicant's estimate at "face value." The estimates should be verified by personnel experienced at estimating costs for pipeline and marine terminal construction.

Chapter 2 - Description of the Affected Environment

Major Items:

(35) Page 14 et seq. (Marine resources). The discussion of marine water quality in Port Angeles Harbor and the Straits of Juan de Fuca does not indicate whether the applicable water quality standards are being met. If they are not being met the causes of the violations should be identified where possible.

(36) Page 57 et seq. (aquatic resources). The discussion of aquatic resources along the pipeline route is poorly organized, hard to use, and incomplete. It should be reorganized so that each stream crossed by the pipeline route is treated as a unit; that is, the physical and biological resources should be discussed together. This discussion should also identify any sensitive downstream resources and water uses which might be affected by pipeline construction or an oil spill.

(37) Public water supplies that are fed by these streams or that could be affected by the pipeline should be identified in the discussion. Their boundaries should be shown on the route/resource maps in the map addendum.

(38) The uses to which ground water resources are put should be identified. Uses which could be particularly affected by construction or an oil spill should be described in enough detail for the reader to be able to understand the sensitivity of the use.

(39) The discussion of surface water and ground water resources should, in addition to listing the applicable water quality standards, indicate whether these standards are currently being met. If standards are not being met, the causes of the violations should be identified where possible.

(40) The Spokane Valley-Rathdrum Prairie Aquifer (mentioned on page 69) should be described in more detail. A map of the aquifer and its streamflow source zone should be provided within the chapter. There should be a summary description of its hydrology and a discussion of why it was designated as a sole source under Section 1424 (e) of the Safe Drinking Water Act. The ability of the soil to "treat" or degrade petroleum prior to its entry into the aquifer should be discussed. If possible the discussion should also indicate the proportion of the aquifer's recharge flow which comes from each of the streams crossed by the pipeline route.

ATTACHMENT I - Page 4

(41) Page 75. The Souris River serves as the water supply for Minot, North Dakota. The EIS should indicate how far upstream of the water supply intakes the pipeline crossings would be. It should also indicate what type of water treatment system Minot uses.

Minor Items:

(42) Page 4. The discussion of the Prevention of Significant Deterioration (PSD) Program is incorrect. All pollutants regulated under the Clean Air Act are subject to the PSD program. Sulfur dioxide and suspended particulates are the only pollutants for which deterioration limits, more stringent than the Secondary Ambient Air Quality Standards, have been established.

(43) Page 10. Map III-2 does not depict the topography of Port Angeles. No map in the Map addendum does.

(44) Page 32. How often is Port Angeles harbor used as a waiting area for tankers enroute to inner Puget Sound crude oil receiving terminals?

CONT

(45) Page 37. The magnitude of recreational boat use in Puget Sound should be stressed. Puget Sound residents have many more boats per capita than the national average. The value of the sport shellfish harvest seems to be too low; the basis for the estimate should be described.

(46) Page 49. The existing climate, air quality, and pollutant dispersion potential for each delivery facility location should be described. Assuming conditions similar to Port Angeles is unsupportable.

(47) Page 52. How has frost heave been eliminated as a problem for oil pipeline construction and operation?

(48) Page 88. The value of Hood Canal for Pacific Oysters should be stressed. We understand that it is the only place on the West coast where they will spat naturally.

(49) Page 6. Conclusions are drawn with regard to daytime and night noise levels but the statistical measure being used (Ldn, Leq, $L_{90}$) is not specified. For each site the dominant noise source and the type of intrusive source which caused the $L_{max}$ during the sampling period should be identified.

Chapter 3- Environmental Impacts of the Proposed Action

Major Items:

Pages 2-8. As you know we still have a number of problems with the air quality impact analyses and their presentation in the DEIS. The concerns

ATTACHMENT I - Page 5

which we have identified to date, in addition to those mentioned in the cover letter, include the following:

(50) 1. The DEIS presents a rather confusing discussion of the fuel sulfur content assumptions which were used in estimating tanker emissions and evaluating compliance with the applicable $SO_2$ standards. The Technical Document indicates a maximum sulfur content of 2% was assumed while the DEIS states in different places that a maximum or an average sulfur content of 1% was assumed. The analysis should probably be based on the expected content (an average of about 2.5% and a maximum of 4.0%). If this analysis indicates that a limitation on fuel sulfur content is necessary in order to assure compliance with the applicable standards, then the analysis should determine what that sulfur content limitation should be. It should then determine whether such fuel is readily available on the West Coast and whether the expected tanker fleet (the ships therein) is equipped with separate fuel tanks to store that fuel for in-port consumption.

(51) 2. The fact that the maximum 24-hour $SO_2$ concentration of 176 $ug/m^3$ would occur only once every five years, as a result of tanker unloading, does not demonstrate that the Class II PSD increment of 91 $ug/m^3$ or the Class I PSD increment of 5 $ug/m^3$ would not be exceeded more than once per year. Additional analysis using terrain interactive models will be necessary to make this demonstration. We have similar problems with the modeling of the combined impacts of the existing facilities and the proposed port facility.

(52) 3. The ballasting emission factor of 0.66 lbs. $HC/10^3$ gallons of water is low by at least a factor of two (see our previous comments on the Technical Document). They will have to be recalculated and the ozone analysis will have to be revised to account for the new emission estimates.

(53) 4. The representative Reid Vapor Pressure (RVP) should be changed to 4.7 psia in accordance with SAI's response to our December 1, 1978 comments. The annual emission estimates for the onshore storage facilities will need to be recalculated to reflect this change, as well as more accurate estimates of the oil storage temperature and the ambient atmospheric temperature. A worst case analysis will have to be done based upon the highest expected RVP accompanied by summer oxidant season temperatures and wind speeds.

(54) 5. Given that the local electric utility does not generate its own power and that it has received a "notice of insufficiency" from its sole supplier (BPA), the EIS should evaluate the air quality impacts of the applicant providing its own on-site power generation on a full-time basis.

ATTACHMENT I - Page 6

(55) 6. Compliance with the annual PSD increment for $SO_2$ in the vicinity of the port site needs to be evaluated and discussed in the EIS.

(56) 7. The need for emission offsets in the Seattle non-attainment area for oxidants and the Port Angeles non-attainment area for suspended particulates should be evaluated in light of the revised EPA Offset Policy.

(57) 8. The FEIS should evaluate the secondary air quality effects associated with the delivery/substitution of Alaskan sour crude for sweet crude oil at Northern Tier states refineries. If refineries do make process changes in order to use more Alaskan sour crude significant air quality impacts could follow. In a number of instances these changes would require the issuance of a PSD permit under the Clean Air Act.

(58) Page 8. EPA assigns the following significance to increased noise levels:

1. 0-5 dBA increase: slight impact
2. 5-10 dBA increase: significant impact
3. 10+ dBA increase: very serious impact requiring mitigation

(59) Page 9. Residents would be annoyed by construction noise from the terminal facility and would be very disturbed by noise from the construction of the onshore storage facility. Operational noise levels at the storage facility would have a very serious impact on nearby residences which merits mitigation.

(60) Page 11. Changes in erosion patterns at Green Point are not evaluated with respect to the "feeding" of Dungeness Spit. Past experience with the relationship between the Elwha River and Ediz Hook would tend to indicate that this could be a significant problem.

(61) Pages 18-34. The oil spill risk/impact analysis merits a number of corrections and expansions: (a) the submarine pipeline risk estimates in the text conflict with those provided in the tables; (b) the in-transit tanker risk estimates apparently ignore traffic density and exposure time as independent variables in the risk analysis; (c) the rationale for the trajectory analyses merits explanation (why were particular months picked and what were the key assumptions in the modeling); (d) the damages associated with a major spill need to be quantified; and (e) the damages associated with chronic spills and discharges in the harbor need to be quantified.

(62) Page 41. Citizen comments at the Port Angeles Public Hearing have raised serious questions about DIW's fire and explosion risk analysis. The numbers presented in the DEIS apparently severely underestimate the damages associated with potential fires and explosions. The analysis should probably be redone and it should address emergency response capability requirements for conceivable "disasters." The estimates at Page 41 appears to conflict with Northern Tier's own estimates (see Page 51).

ATTACHMENT I - Page 7

(63) Page 58. The discussion of the noise impacts of pump station operation should quantify impacts at noise sensitive receptors. It should specify the resulting noise levels and the change in noise levels over existing conditions. In areas where noise sensitive receptors will be exposed to changes greater than or equal to 10 dBA possible mitigation measures should be evaluated.

CONT

(64) Pages 68-80. The discussion of the effects of the pipeline on aquatic and marine resources merits expansion. The information presented on the sediment loads that may be produced during the construction of stream crossings should also note the applicable water quality standards for turbidity and suspended solids. The discussion should indicate for how long a period of time these standards might be violated. The discussion of the effects of a pipeline oil spill at various stream crossings should, for each stream which supports a significant fishery or serves as a potable water supply, quantify the impacts of the maximum possible spill as well as of a spill which was just below the minimum detectable by the pipeline system instrumentation. This quantification should reflect the remoteness of particular sites and the difficulty of moving spill containment and clean-up equipment to the site.

(65) Page 70. There is little or no discussion of the impacts of a pipeline oil spill on potable water supplies or the Spokane Valley-Rathdrum Prairie Aquifer. There should be a generic discussion which provides a detailed chemical analysis of the crude oils to be carried (that analysis should focus on the Priority Pollutants on the attached list). This discussion should give their percentages by volume and weight and describe their physical, chemical and biological characteristics. It should discuss their known and expected health effects when found in water supplies.

Then, on a site specific basis, the EIS should evaluate and discuss the probability of an oil spill or spills reaching individual public water supplies.

For groundwater sources, such as the Spokane Valley system, the ability of the soil to treat and degrade spilled petroleum before it reaches the aquifer should be evaluated.

Minor Items:

(66) Pipeline construction impacts on wildlife in the prairie potholes region of North Dakota need more extensive discussion. The types of impacts that could occur should be described and quantified, where possible. Construction practices and techniques which might reduce these impacts should also be evaluated.

ATTACHMENT I - Page 8

(67) Page 110. The discussion of the effects of pipeline system operation on energy requirements merits some expansion. Although Chapter 2 indicates the magnitude of these requirements on a station-by-station basis, this portion of Chapter 3 does not tell us how significant these power loads would be for the supplying of electric utilities. It should determine which utilities may have difficulty meeting the additional power loads without additional generating resources. For these particular utilities it should then evaluate the air quality effects of the additional generating capacity which would be needed.

Chapter 4 - Mitigation Measures

(68) This chapter focuses on committed mitigation measures, which, in a sense, could be considered a part of the proposed action. What it should do is, based on the impact analysis in Chapter 3, develop additional feasible mitigation measures which would be required by or carried out by agencies of the Federal government. Specific "areas" meriting mitigation measure development are outlined below.

Noise. Construction of the submarine pipelines to the onshore storage facility at Green Point and the operation of this facility might entail significant noise impacts. The FEIS should evaluate possible mitigation techniques, such as modifying construction equipment, restricting nighttime construction activities, and soundproofing adversely affected residences. Under the National Environmental Policy Act, BLM would have the authority to require such actions by the applicant as a condition of receiving a right-of-way across Federal lands.

Aquatic Resources. Additional protection for aquatic resources and potable water supplies from oil spills should be evaluated. For example, the Department of Transportation could require the preparation of a SPCC plan for the pipeline which paid particular attention to these resources. That plan might call for more frequent inspections of stream crossings than proposed by the applicant. It might also require more extensive inventories of spill control and clean-up equipment than proposed by the applicant. It could provide for rapid notification of water supply operators if a spill occurred.

Fire/Explosion Response. The FEIS should evaluate the adequacy of the proposed fire fighting system in light of a revised fire and explosion risk/damage assessment. It should determine what additional equipment and manpower would be necessary to deal with these events and how they could be provided. Possible means of requiring the applicant to meet these needs should be discussed.

ATTACHMENT I - Page 9

The question of the application and enforcement of mitigation requirements is raised and then dropped a number of times in the DEIS. It would be appropriate for the FEIS to evaluate possible Federal administrative mechanisms for monitoring/managing the final design and construction of the proposed transportation system. In particular an organizational structure and management system like that being developed for the Alaska Natural Gas Transportation System should be considered.

Chapter 6, Section 3 - Potential to Supply Puget Sound Refineries

(69) The discussion of the effects of expanding Northern Tier's proposed system to serve Puget Sound refineries needs expansion. First, assuming that the air quality impact forecast is valid, it should be expanded to determine if compliance with the applicable PSD standards is possible with any possible set of mitigating actions, such as limits on fuel sulfur content. Second, it should evaluate the effects of reducing tanker traffic on Northern Puget Sound (reduction in spill risk, reduction in air pollution at refinery sites). Third, it should evaluate the environmental impacts of the pipeline addition from North Bend to the refineries (the spill risk discussion does not quantify probable and possible impacts).

ALTERNATIVE II

U.S. Environmental Protection Agency
Detailed Comments re Analysis of the
Alternatives to the Northern Tier Proposal
(Chapter 8 of the DEIS)

The DEIS' analysis of alternative configurations for the Northern Tier Project and alternative crude oil transportation systems merits major changes in its scope and content. In general the current analysis limits itself to a generic and qualitative comparison of alternatives. It does not address the critical differences in the environmental effects of these alternatives. Our specific comments are presented below in the order in which the topics are addressed in the current chapter.

Port Site Alternatives

The following corrections and additions should be made to the analysis of port site alternatives in the FEIS:

**86** CONT.

(70) 1. Existing environmental conditions (air quality, water quality, noise levels, et al.) should be described in quantitative terms. Compliance with applicable environmental standards should be addressed.

(71) 2. The analysis of air quality impacts improperly assumes that all possible port sites will have meteorological conditions similar to Port Angeles.

(72) 3. The effects of facility wastewater/runoff discharges on water quality should be examined. Compliance with water quality standards should be addressed.

(73) 4. Noise levels as a result of project construction and operation should be predicted. Impacts at noise sensitive receptors are not quantified. Compliance with State noise standards and EPA noise exposure guidelines should be addressed.

(74) 5. The spill risk analysis should account for existing general cargo vessel traffic, barge traffic, products traffic in barges, and recreational boat traffic. The pipeline spill risk estimates conflict with the assumption that length is the primary exposure variable.

(75) 6. The impacts of major and minor oil spills should be quantified.

(76) 7. Impacts on potable water supplies and electrical energy supply systems should be quantified.

(77) 8. The consistency of the alternative port site with the State's coastal zone management program should be evaluated.

(78) Generally, alternative port sites deserve the same detailed analysis and discussion that the proposed port site receives unless the site is technically infeasible. That may be true of the Low Point site because the swing radii for the single point mooring systems may overlap the established navigation channel. That particular problem should be discussed and accounted for in the oil spill risk analysis.

Pipeline Route Segment Alternatives

(79) Cross Puget Sound Pipeline:

The Cross Puget Sound pipeline route segment alternative merits much more attention, particularly now that it is Northern Tier's proposed route. This expanded discussion should address the following topics:

1. Pipe structure and design.
2. Substrate and/or burial material susceptibility to natural removal (and pipe exposure) considering the tidal activity, substrate make-up and bottom contours.
3. Monitoring systems which can be used to detect small leaks/spills before they do significant environmental damage.
4. Failure frequencies for submarine pipelines, corrosion resistance, and other hazards which could lead to a pipeline rupture.
5. The impacts of a pipeline spill (major) provide a quantification thereof.
6. The impacts of the pipeline on anadromous fisheries streams and potable water supplies enroute to North Bend and Snoqualmie Pass.

(80) Stampede Pass Cascade Mountains Crossing:

If the Stampede Pass crossing is a real alternative then a more detailed analysis is required. In particular, a spill risk estimate should be performed and the possible impacts on the Tacoma and Seattle watersheds should be quantified. The costs of protecting these water supplies should be estimated. Possible changes in pipeline design or operational practices which could reduce the risk to the watersheds should also be discussed.

(81) Coeur d'Alene River Alternatives (Idaho):

All three alternative routes cross the Coeur d'Alene River or tributaries to it. The Jackass Ridge route, now the proposed route, merits more detailed and quantitative analysis:

ALTERNATIVE II - Page 3

1. Quantify oil spill risks.
2. Quantify the risk to the Spokane Valley-Rathdrum Prairie aquifer.
3. Evaluate possible mitigation measures to reduce that risk and/or to reduce the possibility of an oil spill reaching the aquifer.

Additionally, alternative route segments which would avoid the streamflow source zone for the Spokane Valley aquifer should be examined.

(82) Ninemile Creek to Helena, Montana:

This alternative poses a potentially severe threat to the environment and potable water supplies in the Helena Valley. The line would cross the Prickly Pear fault. The Valley is characterized by extensive dispersed human habitations which are dependent upon individual wells for their water supply. The risk of an oil spill affecting the ground water supply is thus a serious consideration which merits more analysis in the FEIS.

System Alternatives (under Title V)

As we noted in the cover letter the alternatives to the Northern Tier proposal being considered under Title V merit an analysis similar to that which we have requested for Northern Tier. Particular attention should be paid to the following issues and environmental concerns.

(83) Trans-Mountain Pipeline Co. Proposal:

1. Effects of the terminal and storage facility on ambient air quality in the vicinity of Low Point and in Olympic National Park.
2. Effects of the single point mooring systems (SPM's) on navigational safety in the Straits of Juan de Fuca.
3. Safety of the SPM's at Low Point.
4. Quantification of the effects of a major oil spill at Low Point.
5. Quantification of the effects of chronic minor oil spills at the terminal facility.
6. The ease or difficulty of controlling and cleaning up oil spills in the Low Point area.
7. Changes in Puget Sound tanker and product barge traffic if TMPL also serves Puget Sound refineries from the Low Point terminal. Changes in air quality at existing terminal sites which would result from the reduction in tanker traffic.
8. The availability of spare capacity in existing connecting pipeline systems (without such capacity TMPL cannot serve Northern Tier states).
9. Effects of secondary petrochemical development in the vicinity of Low Point (the same rationale applies here as at Port Angeles).
10. Effects of runoff water discharges on water quality.

(84) Northwest Energy/Foothills:

1. Air quality effects of the terminal and storage facility in the vicinity of Skagway and on nearby National Parks and National Monuments.

ALTERNATIVE II - Page 4

(84)
2. Marine resources at risk enroute between Valdez and Skagway (exposed to the risk of an oil spill). Describe them, their uses, and their economic values.
3. Navigational safety enroute to Skagway, particularly along the Lynn Canal.
4. In-transit and at berth oil spill risks. Quantification of the impacts of a major spill as well as of chronic spills at the terminal facility.
5. Effects of runoff water discharges on water quality.
6. Risks of fires and explosions. Damages resulting from such events. Possible measures which might be required to reduce those risks and/or prepare to respond to such events. (We assume that Skagway's fire fighting system would need a major expansion in order to be adequately prepared for such events.)
7. Effects of secondary petrochemical development if such development appears reasonably possible. If not, explain how this determination was made (what analysis was performed).
8. Effects of facility construction and operation on Skagway's potable water supplies (principally groundwater) and possible water supply protection measures.
9. The availability of spare capacity in connecting pipelines.

Portland, Ore. 97232

Dear People:

I have reviewed the draft Environmental Impact Statement (EIS) prepared by your office and have found it inadequate in several areas:

① (1) Regarding Irretrievable Commitments of Energy Resources -
The Northern Tier Pipeline (NTP) would consume nearly six million KWH of electrical power per day, over twice the average daily energy capacity of Hungary Horse Dam. Montana generating facilities will no doubt have to satisfy at least a portion of this electrical demand. This additional need for power generation, including potential sources or siting of new sources must be related in terms of impacts towards Montana resources. The addition of such a large energy requirement to the Pacific Northwest "power pool" will very likely place an additional demand upon strip mining of coal in Eastern Montana, as well as increase the "need" for additional coal-fired generating plants in our state.

② (2) Regarding Environmental Impacts to Fisheries Resources -
Stream crossings, both large and small during construction of the NTP will cause our State Water Quality Standards for turbidity (sedimentation) to be continually exceeded. Such water quality impacts will, in turn, cause loss of young-of-the-year fish, destruction of fragile aquatic insect food sources and even loss of adult fish because of competition between fish displaced (by sediment) to unimpacted areas of the stream that already have established resident populations. Also, your own projections indicate that pipeline breaks are going to occur, adding the certainty of oil spills as an other significant impact that will occur to Montana's aquatic resources, particularly if the pipeline is allowed to be frequently placed near streams or rivers. The close proximity to streams and the subsequent need for stream crossings could be greatly reduced if the pipeline followed existing rights of way such as major highway networks. Your draft EIS did not address in enough detail the environmental (and perhaps economic) benefits of following such already disrupted rights of way.

③ Also, as far as adequately addressing impacts to aquatic (and terrestrial) wildlife it would seem that any logical review can only occur after selection of the final pipeline route. General impact statements can in no way satisfy the need for evaluations on a site-by-site basis. Hopefully, your final EIS will spell out this most important consideration and, in turn, recommend the need for further site-specific evaluations before granting approval for any phase of construction.

④ (3) Regarding Seismic Activity -
Your draft EIS did discuss in some detail, the earthquake potential existing in the Montana Rockies. As you stated, the potential for significant disruption of the pipeline by earthquakes during the next twenty years is quite high. Is this potential as high with the other three northern pipeline alternative routes? If the potential for disruption by earthquakes is high all along the Rocky Mountains, then perhaps your final EIS should conclude that any West-to-Midwest pipeline is a bad idea.

⑤ (4) Regarding Social Impacts in Montana -
An adequate description of the life styles preferred by a large number of Montanans was not addressed in your draft statement. Many of us prefer the rural, scenic, clean air and water lifestyles that could well be disrupted by the pipeline construction. These impacts both during and after (because of the establishment of a corridor precedent) construction need to be evaluated in your final EIS in terms of the attitudes and feelings of residents in the areas being impacted.

⑥ (5) Regarding the Crude Oil Needs of Montana Refineries -
Montana presently exports well over one half of the crude oil produced in the State. Therefore, even with the discontinuance of Canadian oil shipments in 1982, there would still be an adequate supply for the Billings refineries if proper "paper shuffling" such as regulatory changes and supply trade agreements could be made between states and oil companies. This potential for redistribution of Montana and Wyoming oil must be addressed in your final EIS as a viable alternative to the NTP supplying Montana refineries.

⑦ (6) Regarding Alternatives to the Northern Tier Pipeline -
Although each of the original four "Northern" pipeline alternatives (Numbers 1-4 in your draft EIS, figure 8.4.3.1-1) entail major construction and operating impacts, the "Foothills" proposal certainly has two outstanding environmental (and perhaps economic) benefits, i.e. an already disrupted right of way existing along the Alaska Highway and elimination, or at least reduction of the need for oil tankers, depending upon where the Foothill's Pipeline would originate - near Skagway or Fairbanks (the latter starting point would totally eliminate the need for oil tankers). Elimination of the need for sea-going tankers would also have obvious national defense implications.

⑧ Furthermore, alternative routes, need not be the only considerations in this matter: (a) Reduction in the flow of Alaskan oil to amounts that would be utilized in the West Coast would eliminate the "surplus" of oil in this area. (b) Retrofitting of West Coast Refineries to enable processing of straight, unmixed "sour" Alaska crude would eliminate the need for importation of "sweet" oil mix. (c) Exportation of Alaska crude to Japan in exchange for rights to other oil sources, again essentially "paper shuffling" would eliminate the need for any large West-to-Midwest, so-called "Title V" pipeline.

All of these proposals should also be evaluated in your final EIS as viable alternatives to the Northern Tier Pipeline.

Thank you for your consideration of all of the above concepts in your final EIS.

Sincerely yours,

Ken Knudson

STATE NURSERY
TOWNER, NORTH DAKOTA 58788
[illegible]

March 23, 1979

Bureau of Land Management
700 N.E. Multnomah
Suite 1250
Portland, Oregon 97232

Gentlemen:

① It has come to my attention that the Northern Tier Pipeline in passing through north central North Dakota may go through the S.E.¼ of Section 31, Township 157 N., Range 75W. This quarter section of land is owned by the North Dakota Forest Service and is a tree nursery. The nursery contains many underground irrigation lines and numerous single and multi-row shelterbelts. This coupled with the high value per acre of nursery stock should be adequate reason for the pipeline not to cross this property. If you need additional information, please contact me.

Would you also send me a copy of the proposed location of the pipeline in relation to Towner, North Dakota.

Thank you.

Sincerely,

[illegible]
Nursery Manager

Re: Comments on Foothills Pipeline Proposal, Skagway, Alaska

Gentlemen:

On behalf of Lynn Canal Conservation, Inc., a conservation organization of Upper Lynn Canal residents, including commercial fishermen, the following comments are made on the above proposal.

① a. It was not possible to adequately evaluate the environmental and socio-economic aspects of the plan, since the consultants' study will not be made available apparently until mid April to BLM and or the public. This report should be an integral part of the proposal, but in this instance appears to be treated as incidental, insofar as the public is concerned.

b. LCC adopts the position of the State of Alaska on the draft statement. Many of the concerns which have not been adequately addressed by Foothills, including but not limited to the matter of cost.

② c. What is the impact on the $5 million a year Lynn Canal salmon fisheries? There is little data available on the effect of a spill in inland waters, containment procedures, liability for damages caused to fisheries and to fishermens' gear by tankers or spills, navigation of 50,000-120,000 dwt tankers in the Canal and other issues.

③ d. There is no evaluation of the data accumulated from the tanker traffic in Lynn Canal during the war years when 15,000 dwt and later 30,000 tankers were used by the military to deliver mixed fuels to upper Lynn Canal, about three times a month. No major spills were recorded, however the use of tugs was found to be necessary and use of Taiya Inlet seemed to be marginal at times during severe storms anchorages. Foothills plans to use tankers of six times the tonnage at a frequency seven times that was evident before in the war and postwar times. What will be the operation plan?

④ e. There is inadequate discussion of the alternatives, especially from the standpoint of the West Coast oil glut. The Skagway proposal seems to be primarily addressed to this problem, which conceivably could be a short run difficulty. One of the prime reasons for an all Alaska pipeline was to avoid the potential problems of having the line in a foreign country. Transshipment of Indonesian oil could be arranged through the Long Beach alternative. It appears that the Skagway line lacks flexibility as well.

⑤ f. The instability of the White Pass location proposed for the line has not been reasonably addressed. It would be unfortunate if the only solution would be to blast a trench out of such much of the way, since above ground placement seems unfeasible due to continuous slide problems.

It would appear that a long term solution would call for a Delta connection along the gas line route in conjunction with use of existing ports along the continental United States for foreign oil shipments. This avoids the use of Southeast Alaska inland waters and the practice of short run construction of pipelines in areas which should not have pipelines. Short of a national emergency, it is difficult to envision the need for tankers in the fishing rich areas of the scenic Panhandle of Alaska.

Very truly yours,

President, L.C.C.

Oregon State Director
Northern Tier Project
Room 1250, Lloyd Bldg.
700 N.E. Multnomah
Portland, Ore. 97232

Attn: Ron Sundell

Dear Sir

This letter is a complaint concerning the inadequacy of the "Fire and Explosion Hazards" section of the BLM Northern Tier Pipeline Environmental Statement Draft. Concerning damage resulting from a possible tanker explosion in the harbor of Port Angeles in the BLM study "Fire and Explosion Hazard" Section III, page 19, you give a description of worst probable accident involving a 300,000 DWT crude oil tanker explosion. I'm calling your attention to the map in Section III, page 18. It should be pointed out that directly across the open water from the proposed terminal is the Olympic Memorial Hospital sitting on the bluff. This is the only major hospital on the North Olympic Peninsula and is within one to one and a half miles from the proposed off floating ramp for tankers.

On page 25 of Section III You state that moderate damage would be produced by a 300,000 DWT tanker explosion in the range of from 175 feet to 2250 feet. This is based on hypothesis using a large number of complicated formulas which do not correspond to actual explosion of tankers in the recent past. I would draw attention to comparison of your hypothesized data to the actual explosion of the oil tanker SS Sansinena which occurred in Los Angeles harbor on 12-17-76. Data concerning this report comes from the U.S. Coast Guard report #1672-71895. The SS Sansinena was a 70,000 DWT tanker. The tanker proposed in your worst probable accident hypothesis is a 300,000 DWT tanker. On page 15 and 16 of the Coast Guard report of the explosion of the SS Sansinena it states that heavy damage resulting from this tanker explosion occurred at distances ranging from one and one sixteenth miles to one and one half miles from the site of explosion. It stated that scattered damage which included broken glass occurred as far as three and one sixteenth miles away from the explosion. The SS Sansinena was one fourth to one fifth the size of the tanker hypothesized in your worst probable case. Examples and the actual factual damage as measured by the Coast Guard is two to three times the distance which you state would occur from explosion of a tanker four times as large. There is obviously a serious discrepancy between your hypothesized tanker explosion and what is an historical documented fact.

After reviewing the data on the SS Sansinena explosion and looking at the map of the Port Angeles harbor and the proposed tanker unloading port in relationship to the town and especially in relationship to the community hospital, it is obvious to any logical person that a tanker explosion of the size of 300,000 DWT would cause serious damage and injury and loss of life to a large percentage of the total population of Port Angeles and at the same time would totally incapacitate and damage the only hospital in the area that would

March 29, 1979

Re: Proposed Oil Tanker Dock

serve as emergency service in case of an explosion.

This area of the Northern Tier Evaluation Site needs to be reappraised in terms of: 1) Emergency medical services in the community, 2) Fire and explosion hazards produced by the proposed Oil Port.

I would appreciate an explanation of the discrepancy between the historic facts of a relatively small oil tanker explosion, the SS Sansinena, and your proposed damage of an oil tanker explosion in Port Angeles harbor.

Sincerely yours

John R. Mather

Portland, Oregon 97232

Dear Sir,

I wish to comment on the adequacy of the draft EIS as it concerns the preferred routing of the Northern Tier crude oil pipeline. I am concerned with that portion of the pipeline routing in Montana east of MacDonald pass that runs directly through the Helena valley. The proposed route runs just north of Custer avenue along the north edge of Helena and through the Helena valley. As a resident of the immediate area, I am deeply concerned with the probable impacts associated with the proposed routing.

Upon examination of the draft EIS issued by the Bureau of Land Management, several significant items were discovered. These are outlined below:

1. The proposed Northern Tier Pipeline is a 42 inch diameter pipeline with a maximum capacity of 709,000 barrels of crude oil per day (Draft EIS Summary, page 15).

2. A leak too small to be detected by remote sensing equipment could amount to as much as 3,540 barrels per day at maximum pipeline capacity (Draft EIS, chapter 3, page 65).

3. Soil contamination from this type of leak would continue until it was detected visually and stopped (Draft EIS, chapter 3, page 65).

4. Helena is located in Seismic Risk Zone 3, the highest risk zone for earthquake activity along the entire pipeline route (Map Addendum to Draft EIS, page 5).

5. The pipeline crosses the Prickly Pear Fault, an active earthquake fault (Draft EIS, chapter 3, page 60).

6. Two earthquakes (magnitude 6.0 and 6.25 Richter) have occurred on this fault within the past 50 years (Draft EIS, chapter 3, page 61).

7. The potential for an oil spill resulting from pipeline rupture in the vicinity of this fault would be high (Draft EIS, chapter 3, page 61).

A significant portion of the residents in the immediate vicinity of the pipeline and most, if not all, residents north of the proposed pipeline route depend on wells for water and septic tanks for waste treatment. The impacts of a rupture of a major crude oil pipeline or a chronic, undetected leak in the residential Helena valley are frightening.

In view of the acknowledged seismic activity in the area, the probability of a pipeline break due to earthquake activity in the area and the possibility of a large undetected leak, I feel the draft EIS has been grossly inadequate in addressing the possible impacts of Northern Tier to the Helena valley. More specifically, the draft EIS has failed to address:

① 1. the impacts associated with the proposed routing through the residential Helena valley.

② 2. the impacts of an undetected leak on the groundwater of the Helena valley.

3. the amount of oil required to produce significant contamination of the groundwater.

4. the effect of a contaminated groundwater supply on residential wells and septic tanks in the area.

5. the length of time the groundwater would remain contaminated in the event of a leak or spill.

③ 6. the economic impacts of an oil spill on residents of Helena and the Helena valley.

④ It is probable that a relatively small leak undetected for a period of time could significantly contaminate groundwater sources and adversely affect residential areas in the Helena Valley. In addition, the extensive network of irrigation canals throughout the valley may provide for rapid and widespread dispersal of an oil spill, should one occur in the vicinity of a major canal. This aspect also has not been addressed in the Draft EIS.

In view of the serious implications of routing the Northern Tier pipeline through the Helena valley, I feel a major analysis of impacts is warranted and must take place before this particular segment of the route receives further consideration. Thank you for considering these comments in the final EIS.

Sincerely,

Larry G Peterman

Portland, OR 97232

Dear pipeline EIS writers:

Although I haven't been able to carefully read the entire draft EIS prepared by you on the Northern Tier Pipeline, I have casually reviewed it and talked to several knowledge people in the energy field. With that in mind, I'd like to offer the following general points.

① 1. The real need for the pipeline isn't adequately addressed. When one considers the potential for energy conservation in this country, we probably didn't need the Alaska pipeline, let alone the Northern Tier. Top this off with the tremendous amount of energy needed to transport the oil from the well head, it's totally ridiculous.

2. The potential for a 3540-barrel-per-day leak that can go undetected is criminal. This could destroy ground water and drinking water, stream ecology, and irrigation systems. The pipeline route passes through several such areas where this would be a threat.

② 3. The pipeline will foster heavy industrial growth along its path. This impact isn't adequately addressed and when it is, the environmental impact will be clearly drastic.

As I'm sure you can tell from the above, I'm completely against the Northern Tier pipeline. It's not a matter of which route. The only sane answer is to not build it at all.

Sincerely,

Bill Schneider

[illegible]

March 28, 1979

Murl W. Storms
Oregon State Director
Bureau of Land Management
U.S. Department of the Interior
Northern Tier Project
Room 1250, Lloyd Building
700 NE Multnomah
Portland, Oregon 97232

re: Draft Environmental Impact Statement,
Transportation System Port Angeles,
Washington to Clearbrook, Minnesota
(Northern Tier Pipeline Company)

Dear Mr. Storms:

These comments on the Draft Environmental Impact Statement (DEIS) concerning the proposed Northern Tier Pipeline are submitted by the Northwest Office of Friends of the Earth, a national citizen's environmental organization with 24,000 members. There are 1,200 members in Washington State and many others in other states that will be directly impacted by the proposed construction project. Additional comments on the DEIS may be submitted by other offices of Friends of the Earth.

Friends of the Earth has carefully examined the DEIS and believes that it is seriously deficient in its discussion of the proposed project, the environmental damage which it will inflict, and the alternatives which are available. The following comments are keyed to particular pages of the DEIS and they are also relevant to other similar discussions in the DEIS who's pages are not specifically cited.

① Page 1-11 of the DEIS purports to describe the construction and placement of the underwater pipeline. This description is wholly inadequate. No information is given concerning the method by which the pipeline is to be placed in position beneath the water. No information is given concerning how the pipeline would

Page 2
Murl Storms
28 March 1979

be "buried beneath the harbor bottom" or what means would be used to keep it there. Similarly, the DEIS merely states that the pipeline would be buried at "sufficient depths to minimize the possibility of ships' anchor damage," but does not specify what that depth is. Without this information it is impossible to comment on the proposal adequacy of its environmentally possessive measures since pertinent facts concerning the proposal have not been disclosed. Similarly, the description on page 1-11 of pipeline shutdown in response indications of a leak does not describe in sufficient detail how that shutdown would occur. There is some indication that a leak would precipitate the procedure in which the oil in the line would be replaced with water, but no information is given concerning where or how the displaced oil would be discharged. Finally, if the description of the Submarine Pipeline on page 1-11 is meant to indicate that it would be "thick-walled pipe" consisting of only one wall this raises serious questions about the safety and the environmental soundness of the entire Northern Tier Pipeline Proposal.

② Page 1-55 of the DEIS discusses the so called "minor spills" and asserts that such spills "generally cause minimal impacts." This statement and the entire DEIS's discussion of minor spills are seriously deficient in that it fails to address adequately the severe adverse cumulative effects which minor spills may cause over a period of time. Moreover there is a serious question not adequately addressed by the DEIS concerning the effectiveness of current methods for detecting minor spills and, more importantly for rectifying them once they are detected. Since the DEIS itself concedes that minor spills may occur more frequently than so called major spills, the cumulative effects of such minor spills and the means by which they are to be prevented or corrected must be discussed in more detail.

③ Page 1-57 of the DEIS suggests that the reduction of air pollution while tankers are in port may be accomplished in part by requiring that arriving tankers utilize only "locally supplied fuel of 1 percent sulfur content (currently available)." However the DEIS does not state how this requirement will be enforced. Moreover, there are serious questions not addressed in the DEIS, concerning whether such fuel will be available for arriving tankers. Obviously unavailability of such fuel will preclude the litigation which the DEIS contemplates and therefore this possibility should be discussed. In general, all the "additional

Page 3
Murl Storms
28 March 1979

④ measures proposed for environmental protection" cited on pages 1-56 thru 1-58 are given only cursory attention and should be addressed in greater detail in the Final Environmental Impact Statement (FEIS) particularly in regards to how they will be enforced and their potential effectiveness.

⑤ Page 1-59 contains a discussion of interrelationships of the Northern Tier Pipeline Proposal with the mandates and programs of various federal agencies. It asserts that, "there would be no significant effects on endangered or threatened marine mamals so the National Marine Fisheries service has not been consulted." However, because the National Marine Fisheries Service, component agency of the National Oceanic and Atmosperic Administration, has jurisdiction over salmon and other fisheries, this agency clearly should have been consulted concerning the potential effects of the Northern Tier Pipeline Proposal on fisheries. Failure to do so constitutes a serious defect in preparation of the DEIS and must be remedied before it is issued in final form. Moreover, the conclusions that there would be no serious effect on endangered or threatened marine mamals is one which should have been appropriately made by the agency having jurisdiction over them rather than by the project proponent.

⑥ The discussion of social and economic conditions on page 2-46 of the draft statement underestimates the nature and depth of local opposition to the proposed oil port. Moreover, statements are made concerning desirability, for example, of a more diversified industrial base without making clear rather such statements are attributed to area residents or to the project proponents.

⑦ In general, the draft statement discussion of environmental impacts is deficient in every respect. For example, discussion of adverse air quality impacts is based on questionable modeling assumptions. Even so, the DEIS concedes that platform standards for Olympic National Park would be exceeded, it fails to adequately address implications of such degraded air quality for the national park and the surrounding areas. Similarly the
⑧ DEIS discussion of spill risks fail to present a realistic analysis of frequency with which spill risks incidents may occur and individual or cumulative effect which such spills may have on the environment.

**93** CONT

Page 4
Murl Storms
28 March 1979

⑨ The draft is particularly unrealistic in its assertion without logical support that(page 3-40) it is likely that oil storage facility would remain a single industrial use and that no development would occur nearby. This assumption which is pivotal to consideration of land use impacts by the proposed project and which is of vital concern to the surrounding community should be addressed in more detail. In particular, detailed attention should be given to the possibility that the project will foster development of a petrochemical industry in the area. ⑩ Similarily, the effect of tanker queuing, discussed on the draft page 3-42, and the expected huge increase in port traffic should be examined from all perspectives including air quality, water quality and effect on other local industries which now rely on use and access to port facilities. ⑪ Safety considerations are also slighted in the DEIS including the consideration of danger and impact of fire or explosion on the surrounding area. Thus the statement on page 3-51 that additional independent anayses of fire or explosion are being conducted and are being incorporated into the FEIS fails to provide those reviewing the DEIS with adequate information on which to base their comments.

⑫ The failure of the draft statement to identify mitigating measures with regards to air quality (page 4-2) emphasizes the inadvisability of proceeding with the proposal at all since adverse environmental impacts on air quality promise to be severe. Other possible mitigating measures connected with particular potential adverse impacts are odd. For example the statement suggests that (page 4-3) once submarine pipelines were laid they might be designated as a "no anchor zone" by the Coast Guard. However it is conceded that the Coast Guard may not commit itself to this mitigating measure until after the pipeline has been laid and the proponent is committed to construction of the project.

⑬ In summary, Friends of the Earth beleives that the DEIS is inadequate as an "Environmental Full Disclosure" document designed to form decision makers of the potential adverse environmental impacts and consequences of a proposal. The serious deficiencies evident in the DEIS are reason enough to require a rethinking of the entire project and repreparation of the DEIS. Moreover, the existence of studies recently made public which demonstrate that the Northern Tier Pipeline may not be needed at all calle

Page 5
Murl Storms
28 March 1979

into question the entire premise which the DEIS is based on and specifically raises doubts about whether the draft statement adequately considers alternatives to the Northern Tier Pipeline Proposal. Thus at a minimum, the DEIS should be withdrawn and ammended to reflect consideration of these new studies as they relate to the Northern Tier Pipeline. The Northwest Office of Friends of the Earth continues to believe that a properly prepared DEIS incorporating all available information and involving consultation with all concerned agencies would clearly demonstrate the inadvisability of proceeding with the Northern Tier Pipeline Project. We will therefore continue to monitor the project proposal closely.

Sincerely,

Dale Jones

St. Paul, Minnesota 55155

March 26, 1979

Murl Storms
State Director
Bureau of Land Management
Northern Tier Project
Room 1250, Lloyd Building
700 N.E. Multnomah
Portland, Oregon 97232

Dear Mr. Storms:

The Minnesota Department of Transportation (Mn/DOT) has reviewed the Draft EIS prepared for Northern Tier Pipeline. We offer the following comments for your consideration.

① 1. The Draft EIS acknowledges that Minnesota Trunk Highways No.'s 220, 2, 75, 32, 59, and 92 will be affected by the pipeline construction. The report also identifies that roadbeds crossed by the pipeline will be augered or bored and casing supplied in accordance with Minnesota requirements. Each of these road crossings will require Mn/DOT permits.

The report further indicates that during construction, pipe will be stockpiled at Crookston, Dugdale, and Fosston. It is proposed that pipe from the yards will be transported to construction sites in 40 to 80 foot lengths. The transportation of the pipe would affect traffic on each of the referenced highways and would require extra length permits from our Department for each load if the 80 foot lengths are transported.

② 2. Page 1-21 identifies a State Highway 12 in Red Lake County. This reference should be changed to County State-Aid Highway (CSAH) 12.

3. Page 2-129 references Minnesota Highway 20. This reference should be changed to Minnesota Trunk Highway 220.

③ 4. Our Department has concerns relating to the possible effects the transportation of pipeline equipment may have on the trunk highway system. Extremely heavy loads can damage roadbeds. Of the trunk highways identified in the Draft EIS, several roadways have spring load restrictions and/or year round bridge weight limitations, which could influence pipeline construction. Both Trunk Highway 2 and 75 are year round, 9-ton

Page 2
Mr. Storms
March 26, 1979

roads. For information on other road or bridge limitations, pipeline representatives may contact Patrick Hughes, Area Maintenance Engineer at Mn/DOT's Bemidji Office at (218) 755-3305.

④ 5. Our Department's Aeronautic Division has some concerns about the proximity of the proposed pipeline to the Crookston Minnesota Municipal Airport. This concern is prompted in part by the fact that neither the text of the EIS nor the associated graphics clearly define the pipeline route in relation to the Crookston Airport.

Our chief concern is that the City of Crookston is proposing an airport expansion project. Depending upon the pipeline route, there could be conflicts between the airport and the pipeline.

Another major concern is aviation safety. If pipeline construction takes place in the approach zones to the runways, the construction equipment could become a temporary obstruction. As such, if construction is to take place near the airport, we would appreciate your notifying Richard Thiesen, from our Aeronautic Division, at (612) 296-2552 so that the contractor may be advised on precautions to be taken in the approach zones.

Thank you for the opportunity to review this Draft EIS. Questions on the above comments may be directed to Randy Halvorson, Acting Director of the Office of Environmental Affairs at (612) 296-1623.

Sincerely,

Richard P. Braun
Commissioner

Portland, Oregon 97232

Dear sirs:

This is written testimony which I am submitting to supplement our oral presentation on March 8th at the Missoula hearing on the Northern Tier Draft Environmental Statement. Do not hesitate to contact our office if we may provide any additional information. Thank you.

Sincerely,
A. Peter Funk
A. Peter Funk
Missoula Staff Representative

Testimony Presented to the Bureau of Land Management Concerning the Draft Environmental Impact Statement on the Northern Tier Pipeline Project

Presented at Missoula Public Hearing
March 8, 1979

My name is Peter Funk and I represent the Environmental Information Center. Our organization will be submitting written testimony to suppliment the views expressed today, before the April 2nd deadline. E.I.C. is a Montana grass-roots citizen's organization which has an interest in a wide range of issues affecting the quality of life in our state. I am here today to express some concerns addressed to the B.L.M.'s draft statement: concerns raised both within E.I.C. and by Montana citizens not affiliated with our organization.

The Northern Tier Pipeline is proposed to solve a two-fold problem. A projected crude oil shortfall in the Northern Tier states and a surplus of Alaskan crude oil on the west coast. In the description of the proposal, all figures relating to projected supply and demand in the Northern Tier states have been supplied by oil companies or their consutant firms. ① It is our view that independent data should be used if available, or generated if not presently available, to evaluate this estimated "shortfall" in the Nortern Tier states. This need for independent data is particularly apparent in light of the fact that in the early 1970's, oil company investors in the Trans-Alaska pipeline system testified before Congress that their data indicated the Alaskan Pipeline would not create a surplus of oil on the west coast. 1.

We are now presented with a project to alleviate this surplus; a problem the American people were assured would not exist in the first place. The federal draft statement should not rely on data from sources which have been shown to be inaccurate in the past.

In regard to the elimination of this surplus by the Northern Tier project, the figures contained in the description of the proposal generate concerns that the proposed pipeline's capacity at the peak operating stages would only handle the PRESENT surplus of Alaskan crude oil. Yet by 1985, the increased production of ② Alaskan oil is expected to generate an additional quantity of this crude.[2.] The Northern Tier project's apparent inability to deal with this future supply should be more fully explored in the draft statement.

A further indication of need for the project would be the ③ existence of contractual agreements between the Northern Tier Company and crude oil owners,guaranteeing that there will be a product to fill this pipeline. Such contractual agreements are not mentioned in the draft statement, and should be included in any proper evaluation of the Northern Tier project.

CONT

The document projects a shortfall of crude for Montana, resulting from the cutback of Canadian oil supplies. However, Montana and Wyoming produce enough oil to meet state demands.[3.] This oil is not marketed here presently, but rather exported to other regions because of existing contracts which prohibit the redirection or discontinuance of pipeline deliveries, once ④ established. The draft statement on Northern Tier fails to explore the alternative possibility of redistribution of Montana and Wyoming produced crude, and it's effect on the projected shortfall within these states.

Citizens have also objected to the range of proposed ⑤ alternatives discussed in the statement. The federal draft statement does not address the following alternatives:

1. reducing the flow of the Trans-Alaskan pipeline system to the amount that could be utilized on the west coast.
2. retrofitting of west coast refineries to enable processing of Alaskan oil.
3. the export of Alaskan crude to Japan.

Many residents of Montana feel such alternatives should be explored fully in this type of decision-making document.

⑥ A further state issue concerns the Montana Major Facilities Siting Act. This law is not addressed(or even mentioned) in the list of applicable laws in the B.L.M.'s document.[4.] This has been a clearly expressed concern of Montanans on the draft statement. If the Northern Tier pipeline project is exempt from this law, specific reasons for this exemption should be clearly states.

⑦ Criticism of the assessment of social impacts have centered around the lack of site-specific data. The diversity of the social resource is not shown in the present evaluation.[5.] Impacts of the proposed project will differ greatly on varying Montana social environments. In other words, the same social impacts may not be felt,for example, in the Nine Mile Valley west of Missoula as would be experienced by communities in other areas of our state. Furthermore, the FEELINGS of citizens in the impacted areas should be detailed in the Northern Tier environmental statement.

⑧ Economic benefits in the form of local tax revenues should be analysed more fully. Tax benefits are represented only as a total amount of tax paid to each county.[6.] This does not give Montanans the information to evaluate the economic impact on themselves as individuals. A much more specific breakdown of tax benefits should be included in the final statement.

⑨ No alternatives to the Northern Tier proposal for mitigating social impacts are included in the draft statement.[7.] Northern Tier proposes only to aid localities in applying for government funds to reduce such impacts as road damage, recreation facility strain, difficulties for local business in coping with rapidly changing markets and many other potential impacts. Some discussion of alternative and more effective mitigating measures that have been used in the past on similar projects must be included.

Several inadequacies in the environmental impacts section have also been discussed by citizens.

⑩ Rural residents have expressed concerns over the disruption of shallow or "perched" water tables, many of which are important sources of supply for people, livestock and wildlife. A discussion of the impacts on these resources from the proposed project is not included in the draft and should be fully investigated before the final statement is released.

⑪ Potential oil spills along the route are worrying many. The draft statement gives no adequate justification that Northern Tier's leak detection system is, in the B.L.M.'s words,"state of the art". Surely alternatives must exist to this "state of the art" system, which admittedly could not detect a leak of over 3,000 bl./day of crude oil into our Montana environment.[8.] Justification must be given that this system is the most effective that now exists, technologically, at detecting pipeline leaks.

95 CONT

11 There is also no detailed plan provided by the Northern Tier Company for oil containment and clean-up procedures in the event of a leak. Such a plan must be included in the evaluation of any oil transportation system.

12 No measures have been discussed in the plan to offset the likelyhood of surface water degradation from hydrostatic testing of the pipeline. Northern Tier may add soda ash and bacteriological agents to the test water. The draft statement finds no problems with DIRECT RETURN of this possibly contaminated test water to Montana's streams. Montanans will not accept the assumption that this test water will not degrade the existing aquatic resource. Proof must be shown that the proposed method of returning this water to our streams and rivers will not adversely affect the quality of those waters.

13 The creation of an uninterrupted corridor the entire length of the pipeline route has raised many questions concerning the environment. The possibility of off-road vehicle use on such a corridor is a concern of landowners. Increased access for illegal poaching could adversely impact our big game resource. These questions are not dealt with in any detail.

14 Also in regard to the corridor, the Minerals Leasing Act of 1920 specifies that pipeline corridors shall not exceed 50 feet in width (plus the diameter of the pipe). The draft statement does not explain why the Northern Tier Company can request a permanent 75 ft. right-of-way. It is also the stated policy of the Montana Board of Natural Resources and federal law to require new construction of energy transmission facilities to be located within existing energy corridors. There is no discussion of the future impacts of other energy systems being placed within the Northern Tier corridor. An evaluation of such possible future development must be included.

15 A final area of inadequacy in the draft statement reflects the demand for energy which the pipeline will create within Montana. The Northern Tier proposal will demand 5.6 million KWH of electricity per day, or roughly twice as much as the total daily output of Montana's Hungry Horse Dam.[9] What will be the consequences of this large increase in demand for electrical power? Will we in Montana have our quality of life lessened because of this new demand? Data is not provided to answer these questions in the draft and this is a serious omission, particularly for Montanans.

In summary, it is our view that this document does not independently establish a need for this project. There are some choices, that many feel are valid alternatives to the Northern Tier pipeline, which are not investigated. The non-specific nature of the data in regardto social and environmental impacts, and the insufficient questioning of measures proposed to mitigate those impacts, are serious problems in this document, for all citizens. No matter what one's particular opinions are on this project, the draft statement as presented can not be used as the basis for a sound evaluation of a project of this magnitude. Thank You.

98

Dear sirs of the BLM:

We believe it is totally absurd to assume that Montanans are so gullible and naive as to accept the Draft Environmental Statement as it now reads.

First of all it appears that the Northern Tier Pipeline is, in fact, an extention of the Trans-Alaskan Pipeline.

We believe that the oil companies lied to the American public when they so cleverly assured us that there would be no surplus oil on the west coast if the pipeline was allowed to be built.

But, the fact is, that is approximently 600,000 bbl/day of surplus oil and also that there is 616,000 bbl of oil a day of foreign imported oil

The Northern Tier will cost, according to the May, 1978 calculations, $1.15 billion to build.

We suggest that the oil companies put this money where it will be most beneficial to the American public, not the bureaucratic monopolies.

1 We suggest that this money be spent on the retro-fitting of the oil refineries already on the west coast, so as they could utilize and refine the Alaskan sour crude oil.

This alternative has been entirely ignored by the impact statement.

CONT

We feel that the Northern Tier is under obligation to make some kind of justification for this oversight.

The public has also been informed by Northern Tier that no additional demands of burdens would be placed on Montana's Montana's hydro-electric situation.

The Northern Tier will take approximently 500,000 KWH/day which is almost double of what the Hungry Horse Dam produces in one day.

Are we in Montana really supposed to believe that there will be no additional demands put upon us.

2 No where in the DES is there any mention of Eminent Domain.

This pipeline is considered a common-carrier, but again no mention has been made of it

Some justification must be made for such a grave error on the part of Northern Tier.

Are Montanans to stand by and watch ranch after ranch be condemned so as to fatten the purse of the already obese oil companies.

It seems very strange, indeed, that a critical oil crisis occurs ~~[illegible]~~ everytime the oil companies need a pipeline built.

Water in Montana means life. Water cannot be misused or abused.

3 The Northern Tier will be hydro-static tested which will put a crucial demand on our water resources

Also the discharge from the hydro-static testing must be dealt with.

Soda ash and other biological detergents, which have not yet been properly named, will have to be disposed of.

We want to know when this will take place and how.

4 One very important factor is the ever-changing pipeline route. The DES covers only the original route and none of the alternates.

We do not feel there has been sufficient time and effort put into this category.

Also Northern Tier has been so gracious as to offer help in obtaining federal aid for ranchers for the reformation of the land after the pipeline has been built.

Northern Tier's graciousness has hit the U.S. citizen in the pocket book.

We feel Northern Tier is solely responsible for the reformation since they will be doing the devastation.

Federal aid comes from the tax payers, not oil company benefactors, so don't do us any favors Northern Tier.

**98**
CONT

Northern Tier has also said that minimum damage would be done to our river systems, including our fish and wildlife food.

Eleven crossings have been cited in the DES of the Clark Fork River alone.

With such a wide spread siltating problem how can Northern Tier still only assume minimum damage.

We do not believe this to be a very objective or reliable view.

After all the data compiled on the Alaskan pipeline we feel it would be very beneficial for BLM to take a hard look at the facts.

In conclusion, we in Montana feel the pipe line would be, too, devastating to our environment and way of life to accept it as suitable recommendation.

And we also feel that a temporary pipeline of 20 years is not the answer for the long term energy crises ~~solution~~ situation.

As U.S. citizens we feel that the oil companies should look for an entirely new alternative, not an alternate route.

We do not believe any state should have to cope with any problems inflicted by the Northern Tier.

We ask that this testimony, in its entirety be submitted into the BLM files.

Yours truly;
Bruce F. Roths
Rebecca E. Roths

Gentlemen: RE: NORTHERN TIER PIPELINE PROPOSAL

We have selected two issues concerning the Northern Tier Pipeline Proposal which we feel have the greatest potential for adversely impacting our electrical and water customers.

The electrical energy issue deals with the availability of power to existing industrial, commercial, and residential customers if, during a power shortage, Northern Tier's facilities are exempt from curtailment proceedings.

The District's concern is that the pipeline system, with it's large statewide energy requirements, would accelerate the rate at which the curtailment plan is implemented. Its energy requirements, when added to the rising regional load and burdened by slippage of forecasted operational dates of the WPPSS nuclear power projects, may tend to raise the probability of curtailment procedures during "critical" water years. Added to this is the current BPA allocation formula which after July 1, 1983, will limit this District's firm power allocation to 103 percent of an estimated load for that year as it was forecasted in 1973. Since Northern Tier's proposal did not exist in 1973, neither did its expected large energy requirements. Therefore, this District's estimated loads during the pipeline's operational years will probably fall short of the actual loads by large quantities.

As a result, District customers who do not share the exempt status with a crude oil pipeline system may have to curtail their usage to a greater degree than, other factors remaining the same, they would if the pipeline system was not built.

The other major issue concerns a District-owned water system and Northern Tier's proposed activity at Green Point. Their present plan calls for a deep trench to be dug there to allow the two submarine lines to gradually ascend the steep bluff. If this were allowed, the trench would cut into the aquifer that supplies the existing Bluffs Well and Pumping Station which serves approximately sixty residential customers. This, in turn, would very possibly lower the Well's static water level and bring about salt water intrusion.

Another concern is that normal operational wastes such as oil sludge, or oil from an oil spill will infiltrate our well since, when pumping, seventy-five (75) percent of the water comes from the strait side and twenty-five (25) percent comes from the mountain side.

Also, if Northern Tier plans to pump from wells at the Green Point site they must prove by testing that they will not affect the capability of the Bluff's Well. Any further drawdown of the aquifer than what is being experienced now will have drastic impacts on the existing well.

In summary, the District needs to be assured that the proposed Northern Tier Pipeline System will neither jeopardize the availability of energy to our electrical customers nor adversely impact the water quality or its availability to our Bluff's Well customers.

Sincerely,

John C. Tolan

March 30, 1979
P. O. Box 839
North Bend WA 98045

Bureau of Land Management
Northern Tier Project
Room 1250 Lloyd Bldg.
700 NE Multnomah St.
Portland OR 97232

The draft Environmental Statement for the Northern Tier Project is a deficient description of the planned route. In an attempt to describe all possible alternatives (across Puget Sound, around Puget Sound, etc.), no one has been specifically proposed and completely examined.

The ES does not specifically address:

① 1. The economic issues. The economic justification provided is extremely shallow. The pipeline capacity is not compatible with the oil resource requirements of the intended market. The ability of the refineries in the Midwest to process the Alaska oil is not examined. The ultimate cost to the consumer of the oil products is not considered, especially in comparison to other alternatives supply methods.

② 2. The effect on marine resources. The immediate and long-term effects of the pipeline and construction on salmon spawning areas is not dealt with in the serious manner required by the importance of the fishing industry to the Puget Sound economy. The effects and measures of handling oil spills is not described.

③ 3. The effect on the Snoqualmie Valley. The ES does not make an attempt to enumerate and describe the means of bringing the pipeline through the Snoqualmie Valley. There is no discussion of the North Bend oil storage facility proposal. This facility must be viewed with regards to impact on the area including agriculture, the timber industry, local water supplies, pollution, and security (including fire danger).

④ 4. The impact on landowners in the proposed route(s). It is difficult to specifically identify the route with the limited information provided to the public. The cavalier disposition of the interests of the individual landowners is unacceptable.

In summary, the ES does not identify a specific plan for the Northern Tier Project, justify that plan and, within that justification, concisely describe the total impact on Western Washington and specific measures to be taken to mitigate that negative impact. The ES should be extensively revised to adequately address the described deficiencies.

These comments are provided in addition to the testimony given at the March 14, 1979 hearing on the ES.

I would appreciate receiving adequate notice of any further hearings on the subject and copies of the revised ES when it is available.

COMMENT ON NORTHERN TIER PIPELINE PROJECT

The undersigned, some of the residents and landowners in the Blackfoot River valley, east of Missoula, Montana, offer comment on the draft environmental statement issued by BLM on January 11, 1979, which was the subject of a public hearing in Missoula on March 8.

First, a statement on what this comment is not about:

1. It is not an endorsement of the Northern Tier Pipeline project. Some of the signers are not persuaded by the public evidence of the need for the project.

2. It is not an endorsement of the "route segment alternative" passing through the Blackfoot River valley. At least some of the signers hold the opinion that other alternative routes would cause less environmental impact.

The comment is about matters which the signers believe should govern the choice of route if the Blackfoot segment alternative becomes final.

The Blackfoot River valley is relatively narrow and is traversed by the river and other streams. The small amount of good bottom land available is devoted to growing grain and raising stock. Accordingly, we offer these suggestions for route location:

1. Do not parallel rivers.
2. Do not occupy bottomland or high-yield timber areas.
3. Pursue high ground and ridges wherever possible.
4. Employ the existing Montana Power Co. high-voltage easement passing along high ground south of the river until it reaches the head of Ten Mile Creek in Section 15. Then proceed southwest on a ridge to a point about one-half mile west of the junction of Bear Gulch and the Clark Fork River, from where the pipeline could proceed to the existing corridor.
5. Avoid big game winter range.

In addition, because all water resources serve either domestic or agricultural needs, extreme care should be taken in all stream crossings. All river crossings should be overhead.

Finally, the signers urge that the NTPC spill control program be required to provide remedies for private property damage and contamination of water resources.

BLM - Northern Tier Project
Rm 1250, Lloyd Building
700 N. E. Multnomah
Portland, Oregon 97232

Dear Sir or Madam:

A study of the Summary Draft Environmental Statement for the Northern Tier Pipeline leaves us concerned that the economic, social and environmental effects are not adequately addressed.

① The very real possibility of oil spills is admitted but we do not see a description of adequate means to detect leaks nor to mitigate their very serious effects on ground and surface water. Many other unfortunate results of such a major project on landowners, communities, wildlife habitats, forest ecosystems are apparent and most disturbing.

We are not convinced of the need for this pipeline. Oil production in Northern Canada is increasing, and also in Northeast Montana. Other alternatives besides this huge pipeline extending twice as far as the Alaska line over fault zones, mountains and clear water streams, should be carefully considered before such an environmentally devastating project is undertaken.

Yours truly,

Margaret H. Wright
Philip L. Wright

Testimony - Northern Tier Pipeline by Glen C. Childers, March 15, 1979

To: Bureau of Land Management, Portland, Oregon

We are experiencing today, what might be a truly uncommon development in all of human history. It has to do with the capture of the wealth-generating machine of society-- what we call the economy today-- by people who want to turn it off. The "spoils system", the practice of a political party after a victorious campaign. There are people around today, who want to slow down the wealth-generating machine of society, the economy, for reasons based no less on myth and superstition, than the religious fanatics of another time. These people have been around in great numbers since the 1960's, but only now the "spoils system" is operating to bring them to the seat of power. Like most zealots, they are in almost continual revolt. True believers all, they refuse to notice any person or opinion, which does not conform with theirs. What I don't like is that they are forcing us into their political corner by creating a situation of economic chaos, by stopping every energy operation in sight-- they have created an economic time-bomb that is already ticking away-- irreversibly. The "spoils system"-- Conventional means to meet energy demands, are discredited with scare tactics and condemned as a disgrace to our environment. When the shortages thus produced do finally occur, and massive unemployment and social disorder inevitably follow, then corporations, capitalism and representative democracy itself will be blamed by those very environmentalists who are not capable of any correction. These people, the unaware of their thrust, are attempting to put us back into the stone age where we would wear a breech clout and not disturb the top soil in our efforts to eke out an existance. Any testimony offered by these people, hopefully, will be looked upon with disfavor and we can go ahead with the Northern Tier Pipeline without further delay for many reasons.

**104**

With the increase cost of a limited oil supply from Iran, President Carter's recent oil commitment to Israel, after the year 2000, no further guarantee of the continued use of the Panama Canal and no other pipeline in the offering, it is dangerous to our nation, to further delay the construction and operation of the Northern Tier Pipeline. The following listing summarizes the advantages of the Northern Tier Pipeline.

1 - Would provide economical transportation costs for movement of Alaskan or foreign oil from the West Coast to Northern Tier and upper Midwest refineries.

2 - Port Angeles is the closest U.S. Port to Alaska, the Persian Gulf and Indonesia, the major crude oil producing areas. The proposed marine terminal will be capable of accommodating tankers in the 300,000 dead weight ton class.

3 - U.S. Industry would be stimulated by requirements for steel pipe, tanks, valves, pumps, motors and other equipment.

4 - Incentives for industrial development would be provided in all areas supplied by the pipeline.

5 - Employment, during construction and operations, and tax benefits would be realized totally by the U.S. economy. For instance, Garfield County in Montana would realize in excess of $ 400,000.00 in taxes annually.

6 - Would provide a pipeline completely under U.S. control with embargo-proof characteristics from the West Coast to inland markets, a definite national defense asset.

7 - Would provide a sound, economic long-term solution to the crude oil supply problems of the Northern Tier and upper Midwest states.

8 - The tie-in to the Lakehead system would, in addition to giving access to states and cities as far east as Buffalo, N.Y., provide an avenue for supplying Eastern Canada with crude oil via a U.S. Port.

9 - The Northern Tier Pipeline will replace the supply of crude oil being phased out to our Northern Tier States by Canada and most certainly substitute for the energy lost by the recent closure of the five atomic energy plants due to the dangers of potential earthquakes. If there are any dangers.

The Garfield-McCone Legislative Association, a two County Organization comprised of landowners urges the completion of the Northern Tier Pipeline at the earliest possible time.

Respectfully submitted,

Glen G. Childers, President

March [illegible], 1979

Bureau of Land Management
Oregon State Director
Northern Tier Project
Room 1250, Lloyd Building
700 N.E. Multnomah
Portland, Oregon 97232

Dear Sirs:

We would like to compliment you on your present plan for re-routing the Northern Tier pipeline south of the Rathdrum Prairie - Spokane Valley Aquifer.

Our only concern is that the original plan remains your number one alternate and probably the most financially feasible plan. We do not feel that your impact statement addresses strongly enough the negatives of this alternate. The aquifer is one of our greatest natural resources which with protection has an infinite life span. The financial liability of even a small oil spill jeopardizing its natural cycle far out weighs the benefits of a pipeline with a 20 year life expectancy.

We would encourage you to explore other alternative plans and thank you for your consideration.

Sincerely yours,
Natural Resources Chairman

Julie Carlson

**106** ①

[illegible] FOR PUBLIC HEARING OF MARCH 15, 1979 FOR [illegible]

I find shortcomings in the NT draft impact statement on Air Quality. In my opinion the impact of the NT Pipeline proposal on the environment and the long-term environmental losses have not been discussed in sufficient detail as requested in the State Environmental Policy Act. (Chapter 463-46-440) The serious ecological problems of acid rain and effect of hydrocarbons emissions on human health have been ignored.

ACID RAINS.

Acid rains and snows have well documented undesirable effects on aquatic life in lakes and plant life in forests. (1,2,3) The potential decimation of fishlife in our lakes and streams and the retardation of forest growth will have a serious effect on our industrial economy, tourist business and quality of life on the Olympic Peninsula.

Acid rains result from the oxidation in air of the pollutants, $SO_2$ and $NO_x$. The products are sulfuric and nitric acids. The air is cleansed of these corrosive compounds by rain and snow and fall to the ground as acid rain. Extensive studies of its deleterious effects have been reported. Some of the findings are:

1. Decline in fish population in Norway has been correlated with acidity of streams and lakes, and trout and salmon are seriously affected by pH's less than 5.5. Newly hatched fish are most vulnerable to acid. The pollutants originate in England and Europe.

2. In Sweden about 10,000 lakes have been acidified to pH's less than 6, 5000 of which are below pH 5 and fishless.

3. In the Adirondack Mountains of New York 51% of the mountain lakes have a pH < 5; and 90% of these lakes have no fish. During the period of 1929-37 only 4% of these lakes had a pH of ≤ 5 or were devoid of fish.

-2-

Fishermen no longer find this region the paradise it once was. Tourists avoid the region for this reason.

4. Forest growth has been reduced in southern Scandinavia and in the northeastern U.S. between 1950 and 1970. Norman Glass of EPA estimates that forest production is off 14%. (3) The reason is uncertain but acid rain is a suspected cause. In this connection, however, laboratory and field tests have shown that acid precipitation can affect the germination of conifer seeds and the establishment of seedlings.

The problems of acid rain cannot be ignored. The Northern Tier facility will increase the burden of $SO_2$ for the area by 20%, and of $NO_x$ by 11% at the 933,000 barrels/day level, according to the data of Table 3.12-6.

As far as I know no acid rain measurements have been made on the Olympic Peninsula, nor has any modelling data been obtained. An approximation method for calculating rainfall pH on a multi-state scale has, however, been developed by Pacific Northwest Battelle scientists.(4) The pH of the Olympic National Park's lakes and rivers should be taken and the pH of its rains and snows monitored. Then with the Battelle approximation method it should be possible for Northern Tier to forecast the future acidity of these bodies of water caused by the $SO_2$ and $NO_x$ pollutants. When the pH of these lakes and streams reaches 5.0 they will no longer support fish. For us on the Olympic Peninsula, this acidity hazard is fully as important as the primary pollutants, $SO_2$ and $NO_x$.

HYDROCARBON ISSUE 2.

It is stated on page 3-6 that "hydrocarbons in themselves do not prove to be a health hazard." This statement reveals a careless disregard of the facts. It may apply to the aliphatic or saturated hydrocarbons, but it does not apply to the aromatic hydrocarbons. And since 40% of the whole

-3-

Prudhoe Bay crude oil consists of aromatic hydrocarbons, (5) the impact statement must consider the effects of these compounds on the health of the community.

Benzene, soot, tars and oils are listed among known chemical carcinogens (6). Because benzene, the simplest of the aromatic hydrocarbons, is on the list, it is highly likely that all of its derivatives, as well as all of the condensed ring compounds, present in the Prudhoe Bay crude oil, are potential carcinogens too. While these compounds are much less volatile than

**CONT**

the saturated hydrocarbons used for gasoline, nevertheless they gain access to the atmosphere from spills on the water, on the land, and particularly at the tank farm. Hydrocarbons have been indicted by some as a possible cause of lung cancer. Port Angeles will receive a 36% increase in saturated hydrocarbons, but the cancerous aromatic hydrocarbon content of the air will be increased many-fold.

A recent study found that lung cancer deaths in Texas, especially in the industrialized Houston area, had increased by 53% between 1969 and 1976. (7) The incidence of lung cancer is significantly higher in Texas than in the U.S. as a whole. The area is primarily in the petrochemical industry. While smoking may account for about 50% of the lung cancer cases, the question now is, can rapid population growth and industrial expansion account for the remaining 50%? This University of Texas study does not know.

There are several unknown factors regarding the health hazards of air pollutants. It is stated on page 3-6 that the saturated hydrocarbons are harmless, but what is not known is the toxicity of their oxidized compounds. These products are aldehydes and ketones and they would be expected to be of considerably greater toxicity than the hydrocarbons themselves. Furthermore, those compounds behave more like free radicals, and

-4-

there is one school of thought that regards free radicals in almost any form as potential carcinogens. (8) The remaining hydrocarbons, even without oxidation, are possible carcinogens, especially those in the aromatic and condensed ring systems. The problem here is the same as with that of radiation - what is the threshold? How dangerous are low doses? These matters have recently been discussed. (9) At the present time no one knows whether or not a threshold exists.

A group correlated lung cancer deaths in twenty countries, including the U.S., which have varying degrees of air pollution. (7) From this study the group concluded that lung cancer as indexed by benzopyrene correlated with lung cancer deaths even when cigarette smoking was eliminated as a factor. The group calculated that a microgram of benzopyrene/1000 $m^3$ of air appeared to be associated with a 5% increase in the incidence of lung cancer. They also concluded that a 60% reduction in air pollution might result in a 20% reduction in lung cancer.

An insidious property of the Prudhoe oil is its large fraction of aromatic hydrocarbons (48.5%), all of which are probably cancerous to man. I have already stated that benzene is a carcinogen to man and the benzopyrene mentioned above is carcinogenic at less than one part per trillion parts of air. The residents of Clallam County, particularly those of the Port Angeles and Sequim areas, should be apprised of the potential hazards of these hydrocarbon emissions. A thorough treatment of this aspect of aromatic hydrocarbon pollution must not be omitted from the Northern Tier Environmental Impact Statement.

BLM Northern Tier Project
Room 1250 Lloyd Building
700 N. E. Multnomah
Portland, Oregon 97232

Sirs:

I am submitting this as my written testimony regarding the DES on the proposed Northern Tier Pipeline. I shall attempt to be as brief and concise as possible.

First of all, while I appreciate the BLM's attempt to avoid the usual pitfall of turning out an unreadable behemoth for a report, I fear that you have gone too far the other way. The magnitude of the proposed project demands a more thorough coverage. As presented, the DES falls far short of meeting the NEPA requirements. It is simply too full of generalities, lacking in supportive data for many of its assertions, and completely void of crucial material on many subjects.

① Some of the areas, that I believe you must cover far better, are the revegetation plan or procedure, particularly in areas where there is a substantial danger of soil erosion; the impact on the people who's land the pipeline would cross in spite of opposition, i.e. the imposition of eminent domain; and the nature of alaskan crude oil, such as its volitility, water solubility, and its toxicity to all living things! Additionally, your discussion of the alternatives and even the need for and economic viability of this program is insufficient. Then, too, some models of the actual tax impact on individuals and businesses in each county along the right of way should be included. A question that should be explored, but was not, is the effect of default by the company after, before, or during the abandonment phase. You must also include something more specific about what Northern Tier has proposed for the abandonment phase. Perhaps one of the most obvious ommissions is an adequate explanation as to why Northern Tier is asking for a right of way that exceeds the limit set by the 1920 Minerals Leasing Act.

The above testimony regards the DES as a whole. I would now like to focus my remarks on the DES treatment of the area in which I live. However, I would like to state that I believe that the inadequacies of the DES in regard to this particular area are symptomatic of the insufficiency with which it deals with the entire route, with the possible exception of the Port Angeles area.

② I live in the Western portion of Sanders County, Montana. More specifically in the Prospect Creek drainage. My property is encompassed by an area designated as "The Prospect Creek Planning District" by the U.S. Forest Service. They have done the type of research required to meet the NEPA standards for environmental statements, yet the BLM has not availed themselves of this readily available and extremely valuable information for inclusion in the environmental statement on Northern Tier. The publication refered to is USDA - FS - R1 (16) FES - ADM - 76 - 23. The information contained therein is crucial to any statement about the impact of any major project in the area. It brings out such facts as five existing faults that the pipeline would cross as it passed through the creek bottom, which while currently inactive, are very real dangers to any pipeline, partially because we know nothing of their history; the potential for erosion; the nature of the vegetation; the difficulties of revegetation of such an area; the delicacy of the entire ecosystem present there; and areas of slope instability. The BLM's DES, however, makes mention only of the possible eyesore of a pipeline passing through an area with high scenic value. The DES really doesn't even give consideration to the beavers, muskrats, mink, ducks, geese, owls, Blue Herons, eagles, and piliated woodpeckers that live in this area, not to mention people. Furthermore, when I purchased my property last year, there was a prominent statement about the property being in a flood plain written on the contract. Nearly the entire area is so classed and the proposal by Northern Tier as presented in the DES map addendum fails in totality to meet with Montana law concerning the crossing of flood plains; this fact being entirely overlooked in the DES. This matter is utterly crucial and yet isn't even acknowleged in the DES. This geographic area is even omitted from your tables on rivers and streams! This is an extremely sensitive area and yet Northern Tier has proposed no alternate route to it, nor has the BLM. WHY? Is someone getting paid to ignore a potential powderkeg?

The Prospect Creek Planning District is only one of eight such districts in the LOLO NATIONAL FOREST alone through which Northern Tier proposes to pass. Each national forest through which it passes should be able to provide similar information on its planning districts as the publication listed above. Please, do your homework. Include this information in the final statement or it will have to be challenged in court.

My testimony would be far more extensive except for the fact that for the last fifteen days my wife has been in critical condition in a hospital due to an auto accident. She also wished to make testimony about the DES, but is unable to do so at this time as she is in a coma. However, from our previous dicussions of the matter, on her behalf I would like to say, that she feels the DES absolutely fails to meet the intent, spirit, or letter of stipulations of the National Environmental Protection Act regarding environmental statements!!!! Go back to the beginning, and this time do it right.

Sincerely,

James R. Frye

James R. Frye
Box 549
Thompson Falls, Montana
59873

P.S. For a more detailed disection of problems with the DES, please refer to the testimony presented by Mr. Charles Kay of Fairbanks, Alaska.

Whom Concern:

I did not attend hearings to foot hills Proposal to build a pipe line from Skagway to Keg River Alberta at meetings in Juneau and Skagway. I am a former retired Alaskan commercial fisherman who has fished for years in Lynn Canal area. The tankers coming up canal have no trouble going up canal and hindering fisherman. The winds and storms there are no worst ~~than~~ they have V all day when tankers come and go there if ~~[illegible]~~ bad the tankers just wait until storm dies down. There has been no oil spills there yet. Its just

CONT

II

a stupid reasoning about people talking about spills with a strict regulations from US Coast guard. Skagway and all of Alaska would be affect by the oil line it helps stimulate employ more where its needed. Port Angeles is Crowded and booming Cause Congestion so lets build it where there's no congestion and heavy population. most of people in Skagway wanted the oil line to help boost there economy since railroad is in bad shape financially. This would mean more work for people and other people also the tanker route be

3

the shortest and oil line the shortest of rest of other Proposals, and also oil from Alberta Canada back on to oil line from Skagway furnish $ more oil for U.S. And part of it going into canada make us better terms with Canada and Canadians help us out on energy situation in U.S.A. I believe its only one better than Northern Tier, California and trans mountain the Cheapest ~~[illegible]~~ easiest and less Complications. So I advocate build it at Skagway Alaska

March 28, 1979

Bureau of Land Management
Northern Tier Impact Statement
700 N.E. Multnomah, Suite 1250
Portland, Oregon 97232

Comments of No Oilport re: Draft Environmental Impact Statement Crude Oil Transportation System.

① It is respectfully submitted that the draft impact statement is inadequate for several reasons. The major reason that the impact statement is inadequate is because it presents inadequate data from which decision makers could draw any adequate conclusion. It is also our feeling that the impact statement is inadequate because of failure to discuss significant legal impediments to various proposed projects and failure to consider alternatives in any detail where there are temporary statutory or regulatory impediments to the project. One last major error in the impact statement is the passive role taken by the writers of the impact statement which hasapparently led them into faulty assumptions and incorrect premises.

## INTRODUCTION

NEPA is in effect an environmental full disclosure law (42 Fed2d, 697). Its purpose is to force decision makers to weigh all the environmental ramifications of a project carefully and to consider the quality of life for future generations, not just for Americans old enough to vote. To this end, the Bureau of Land Management should be exercising its full authority to obtain all relevant information from the applicant.

## INADEQUATE DATA

The impact statement appears to be a "captured" document in that most of the sources of information are the Northern Tier application, or Northern Tier supplied data. Because No Oilport did not submit its written comments before the public hearings, we are in a unique position of demonstrating Northern Tier's lack of "full disclosure". Northern Tier, although it has been discussing the cross sound route as an "alternative", waited until after the end of all public hearings on various impact statements to announce that it was in fact changing the project design and route. Thus, there was no opportunity for public comment on this changed route. This certainly does not comply with the environmental full disclosure tenets of NEPA. The Bureau of Land Management Draft Impact Statement has not apparently requested much of Northern Tier. Although BLM has authority under 43 USC 1761 to require

that the applicants submit and disclose all plans, contracts, agreements or other information reasonably related to the use or intended use of the right of way including its effect on competition as well as the name and address of each shareholder owning 3% or more shares and the name and address of each affiliate of the entity together with ownership information of that affiliate, BLM has not exercised that authority. There should be disclosures. There should be discussions of all related uses such as petrochemical industry, particularly when one of the major stock holders in the Northern Tier Corporation, U.S. Steel, is heavily involved in the petrochemical industry.

BLM, of course, also has clear authority to require extensive mitigating measures (43 USC 1764) including but not limited to bonds and security to insure compliance with all proposed restrictions and regulations. However, BLM has not taken the effort to disclose in the impact statement what conditions it would impose upon the pipeline company. Failure to disclose these conditions does not allow the public to have full and fair comment upon the impact of the project. It is, of course, possible, that the conditions imposed upon the project would make the project either more or less environmentally desirable but the conditions are not disclosed. The impact statement recognized air pollution problems but does not disclose the long term effects of the air pollution. The impact statement does not disclose what the economic impact of added pollutant source in the Port Angeles area would be. For instance, there is not disclosure of whether or not additional industry would be able to locate in the Port Angeles area after the Northern Tier pollutant source is located here.

For the underwater pipeline route, the impact statement does not disclose the pressures needed to pump the oil to the depths to be encountered and up again at the low temperature to be encountered. The impact statement does not disclose what the pressure on the pipeline would be from the water and atmosphere at that particular depth of the pipeline. The impact statement does not discuss how the subterranean underwater pipeline would be inspected over the 20 year anticipated life of the project. The impact statement does not disclose any oil spill risk analysis for the submarine pipeline.

The impact statement also does not disclose what impacts there would be with multiple pipelines or multiple oil ports or a combination of pipelines, oil ports and oil trades and exchange between foreign countries.

Perhaps the most significant deficiency is the failure of the impact statement to even consider whether or not a policy of rushing to use up the finite supply of petroleum is a wise decision. The impact statement simply assumes that such a decision is wise and then simply tries to find the least harmful way to implement that very questionable decision.

Bureau of Land Management
Page Three

LEGAL IMPEDIMENTS

Although the DES points out legal impediments to other competing oil transportation projects, it does not address legal impediments to the Northern Tier project in any detail, if at all. At page 1-60, 61, the DES incorrectly states that Clallam County is presently reviewing its Comprehensive Plan. While this is technically true, Clallam County has already revised its Comprehensive Plan and that plan totally prohibits the Northern Tier or any other pipeline proposal for a terminal, storage facility, refinery, pipeline or other petrochemical industry.

Page 1-61 contains the statement that EFSEC has pre-emptive authority over local land use and zoning controls. This is not correct. This is not a clear reading of RCW 80.50 and it should at least be pointed out that there is a dispute as to whether or not EFSEC does have pre-emptive powers over local land use and zoning controls. In fact, there is litigation in Washington courts on this matter.

At the same page the impact statement fails to point out that Clallam County shoreline master program has an additional legal bar to the project. The DES at 6-3 points out the existence of the Evans Policy Statement and the July 1977 proposed amendment to delete that Policy Statement from the Washington Coastal Zone Program. The DES section fails however to point out the illegality of the Evans Policy Statement as pointed out in the draft impact statement prepared on the proposed WCZMP Amendment No. 1 dated November, 1978, and has pointed out in pleadings seeking to declare the Evans Amendment and/or the entire WCZMP void, found in cause no. C77-578 filed in the United States District Court for the WesternDistrict of Washington. The DES fails to consider the effect of the Marine Mammal Protection Act PL95-136 as amended October 18, 1977, on the Northern Tier proposal. That act clearly prohibits federal approval of various facilities for the transportation of oil if that oil is other than for consumption in the state of Washington. The pumping stations on either end of the submarine pipeline systems are certainly facilities as is thepipeline (as defined in RCW 80.50 and similar federal acts). These facilities are in, on or adjacent to navigable waters of the state of Washington east of Port Angeles. Since the BLM has failed to require Northern Tier to specify the location of the terminal facilities berths, it is not aware that the proposed berths as discussed by Northern Tier in various local discussions are perhaps in and certainly adjacent to navigable waters of the state of Washington, east of Port Angeles. The impact statement fails to consider its own generated data which shows that oil spills from the terminal would be in, on and affecting navigable waters of the state of Washington east of Port Angeles. A litoral reading of the act also makes it abundantly clear that an oil port which is located just west of the eastern boundary of Port Angeles is going to necessarily be adjacent to navigable waters of the state of Washington east Port Angeles. Thus, Northern Tier has the same legal impediments to the construction of its project as do proposals for ports at Cherry Point, Burroughs Bay and projects for expansion of docks such as the dock expansion of Mobile. It is therefore reasonable to assume tht some statotory amendments may occur. If they do, Congress should have the raw data available to evaluate all proposals for the transshipment of oil; not just one.

March 28, 1979
Bureau of Land Management
Page Four

Page 17 of the Washington State Coastal Zone Management Program of 1976 points out that "prevailing state policy at this time indicates that the state (Washington) is not interested in becoming a major petroleum processing center or transportation terminus for a major new pipeline to the midwest. Though how much additional petroleum traffic would actually be generated is not entirely clear". This section of the WCZMP has not been addressed by the BLM DES.

The DES gives an extensive list of acts, rules and regulations which may be legal impediments to the Northern Tier project but does not explain how they may be legal impediments and whether or not any of the alternatives competing proposals would not have them as impediments. It is submitted that it is not reasonable that a proposed oil port which would be the nation's largest oil port have such little information disclosed about it.

At Page 5-11, it is suggested that adverse impacts such as the increase in population of about 300 people could be mitigated 100% by grants or loans received as a result from the construction of the project. It should be pointed out that unless these grants or loans are directly contributed by Northern Tier Pipeline Company, as a requirement of their BLM leases, a federal pass through to state government would violate the state constitutional provisions, against gifts or loans and credit for the benefit of private corporations. Authority to mitigate much of these minor but unavoidable adverse impacts is contained in 43 USC 1764 and 1765, but has not been addressed by the BLM.

43 USC 1765(b)(v) requires location of the right of way along a route that would cause least damage to the environment, taking into consideration feasibility and other relevant factors. The BLM DES does not even attempt to suggest what route should be used but merely acquiesces to the Northern Tier proposals. Considering that BLM is a lead agency, this is ludicrous. Section 1765 requires that the terms and conditions "minimize damage to scenic and aesthetic values and fish and wild life habitat and otherwise protect the environment; require compliance with applicable air and water quality standards established by or pursuant to applicable federal or state law and require compliance with state standards for public health and safety, environmental protection and siting, construction, operation and maintenance of or for rights of way for similar purposes if those standards are more stringent than applicable federal standards. There is no discussion that the BLM is bound by the more stringent state standards relating to the siting of rights of way for oil transshipment. There is no discussion that the proposed Northern Tier project will meet or not meet applicable federal or state air and water quality standards. And of course there is no discussion of any BLM suggested changes in the routing of the right of way.

March 28, 1979
Bureau of Land Management
Page Five

FAULTY ASSUMPTIONS

At page 6-1 the DES totally fails to address a relationship between local short term uses of the environment and the maintenance and enhancement of long term productivity. If this project (Northern Tier) succeeds in providing an increase in oil available for producing refined products, and a consequent increase in the use of those refined products, or even if the project merely succeeds in maintaining the "flow" at current consumption rates, it necessarily follows that the finite quantity of all total oil reserves available to the United States will be more quickly reduced then if there were no pipeline maintaining or increasing supply. In short, if the oil reserves, without the Northern Tier project would last longer than twenty (20) years, then the Northern Tier project's effect on the maintenance and enhancement of long term productivity is a completely negative effect. That is, the project would merely hurry to use up the limited oil reserves available at the expense of future generations. The DES totally fails to address the consequent decrease in long term productivity brought about by a project whose goal is to more rapidly use a limited resource.

CONCLUSIONS

It is submitted that there is a failure of the BLM impact statement to consider whether or not the project is needed versus whether or not it is wanted and what its real long term effects would be as well as a failure to consider any of the alternatives seriously, including those originally proposed by Northern Tier as alternatives and now adopted by Northern Tier as a proposal (cross sound pipeline). These factors make the draft impact statement into little more than a reorganization of Northern Tier produced literature. Failure to consider legal impediments to the Northern Tier project while fully considering legal impediments to all other alternative projects, heightens the obvious bias presented in the impact statement. Failure to seriously consider all alternatives violates the duty imposed upon the BLM as the lead federal agency. Recognition that the site's specific impacts within a two mile wide study corridor could be substantially different depending upon the location of the route within that two mile corridor is an admission that the BLM has totally ignored 43 USC 1765(b)(v).

The serious failure to point out 43 USC 1765(a) and that if Northern Tier is denied certification by the State of Washington or by any other state, that the federal government is in effect prohibited from granting any approval of rights-of-way, and that the state standards, not the federal standards apply to the project and must be required of the applicant by the BLM if the state standards are more stringent than the federal standards,makes the DES totally deficient since it does not delineate the applicable more stringent state standards. In summary, the deficiencies in the impact statement do not allow a great deal of critical comment because of the glaring lack of detailed information even on such things as the actual route selected by Northern Tier.

RE: NORTHER TIER PROJECT DEIS
(OUR SAI# 00191708)

SIR:

THE IDAHO STATE CLEARINGHOUSE HAS COMPLETED REVIEW OF THE NORTHERN TIER PIPELINE DRAFT ENVIRONMENTAL IMPACT STATEMENT. THE FOLLOWING STATE AGENCIES AND STATE AREAWIDE CLEARINGHOUSES WERE REQUESTED TO REVIEW AND COMMENT ON THE DRAFT STATEMENT:

AREAWIDE CLEARINGHOUSES:
- CLEARWATER ECONOMIC DEVELOPMENT ASSOCIATION; MOSCOW
- PANHANDLE AREA COUNCIL; COEUR D'ALENE

STATE AGENCIES:
- IDAHO HISTORICAL SOCIETY
- CARY JONES; OFFICE OF THE GOVERNOR
- NATURAL RESOURCES BUREAU; DIVISION OF BUDGET, POLICY PLANNING & COORDINATION
- IDAHO HISTORICAL SOCIETY
- IDAHO DEPT OF FISH & GAME (COMMENTS ATTACHED)
- IDAHO DEPT OF LANDS
- IDAHO DEPT OF PARKS & RECREATION
- IDAHO DEPT OF WATER RESOURCES (COMMENTS ATTACHED)
- IDAHO DEPT OF TRANSPORTATION-HIGHWAYS DIVISION
- IDAHO OFFICE OF ENERGY
- IDAHO PUBLIC UTILITIES COMMISSION
- IDAHO DEPT OF HEALTH & WELFARE-ENVIRONMENT DIVISION (COMMENTS ATTACHED)

THE DEPARTMENTS OF FISH & GAME, WATER RESOURCES AND HEALTH & WELFARE-DIVISION OF ENVIRONMENT SHARE MAJOR CONCERNS NOT FULLY ADDRESSED IN THE DRAFT. THESE INCLUDE: EVALUATION OF THE COEUR D'ALENE SOUTH FORK AS AN ALTERNATIVE ROUTE; ASSESSMENT OF THE IMPACT OF HYDROSTATIC TESTING; CONSIDERATION OF SPILL DETECTION, IMPACT AND CLEAN-UP; AND ASSESSMENT OF ENVIRONMENTAL IMPACT ON CONSTRUCTION AS WELL AS DECOMMISSIONING OF THE PIPELINE. AN ABSTRACT OF COMMON CONCERNS EXPRESSED BY AGENCIES HAS BEEN SUBMITTED BY PAUL CUNNINGHAM, CHIEF OF THE NATURAL RESOURCES BUREAU. ADDITIONAL REMARKS ARE INCLUDED FOR YOUR CONSIDERATION IN THE WRITING OF THE FINAL EIS.

THANK YOU FOR COOPERATING IN THE ENVIRONMENTAL REVIEW PROCESS. PLEASE CONSIDER THE ATTACHED REMARKS IN YOUR FINAL EVALUATIONS.

SINCERELY,

PAM DEMO-RYBUS; CLEARINGHOUSE COORDINATOR

①

Comments on the Northern Tier Pipeline Draft EIS

I will present a summary of the major concerns of the State natural resource agencies. First of all, I would like to compliment the BLM and the Northern Tier Pipeline Company on the completeness and high quality of the draft EIS. We find that the proposed route through Idaho to be the most satisfactory of all the alternatives offered. We do, however, have some reservations about the draft EIS.

First, we feel that the draft EIS should have addressed and evaluated the south fork of the Coeur d'Alene route as an alternative.

Secondly, we are concerned about the volume of water that will be required for the hydrostatic testing of the pipeline. We feel that Plummer Creek and Pritchard Creek may not provide adequate volumes of water for the purpose without adversely impacting these streams. We would like to see the south fork of the Coeur d'Alene and St. Joe considered as sources of water for hydrostatic testing. We would like to be assured that the testing screens out fish, because fish would surely be killed if they were put through the pipe.

Thirdly, we would like to be assured that the contingency plan for oil spills and other accidents be reviewed by the State. Along those same lines, we feel that the present spill detection program is inadequate as a spill of a volume of three to four thousand barrels per day could conceivabley occur and not be detected by line sensors. Alternative and more sensitive means of detection of spills need to be addressed.

It is difficult to discuss decommissioning of a pipeline when you don't even have one pipe in the ground, but we feel that the draft EIS should cover all aspects of the pipeline from A to Z and that the eventual decommissioning of the pipeline and the associated impacts were not adequately discussed in the document.

The draft EIS acknowledges several federal programs such as RARE II, the Clean Air Act and the Safe Drinking Water Act, but does not address local 208 Water Quality plans. We feel this is an oversight and should be addressed because of the noted high erosion hazard along some of the proposed pipeline route and because of the number of watersheds crossed.

We feel that there should be some control of the access to the corridor of the pipeline for both safety reasons such as vandalism and sabotage and from an environmental standpoint such as off-road vehicles and hunters.

Finally, the draft EIS did not adequately discuss the necessary commitment of State resources to monitor both the construction and operation of the pipeline for compliance with State laws.

PAUL M CUNNINGHAM; CHIEF
NATURAL RESOURCES BUREAU
DIVISION OF BUDGET, POLICY PLANNING & COORDINATION
STATEHOUSE

March 12, 1979

Bureau of Land Management
Oregon State Director
Northern Tier Project
Room 1250, Lloyd Building
700 N.E. Multnomah
Portland, OR 97232

Dear Sir:

We have completed our review of the Northern Tier Pipeline draft environmental impact statement. Our review was primarily directed toward that portion of the pipeline that crosses Idaho and the impacts that it would have on fish and wildlife resources. Although we found the statement to be generally adequate in addressing the impacts, we did find some errors in the text along with a failure to adequately describe the full impacts of specific construction and operation phases. Our comments follow.

① Page 2-96, Table 2.1.2.9-1 - In Idaho, wintering bald eagles are also located along the Coeur d'Alene and St. Joe Rivers, as well as Mission Slough.

Page 2-100, Table 2.1.2.9-3 - Cave Lake has less than 10 pair of nesting and breeding Canada geese, not 10,000. Benewah Lake has up to 20,000 wintering waterfowl, not 300.

② Page 3-67, 3.2.6 Aquatic Resources, Construction Phase - The impacts created by hydrostatic testing of the pipeline are not adequately addressed. More specific information is necessary pertaining to location of water withdrawal, time of the year tests would be conducted, screening of intakes, type of bactericide and its effect on aquatic organisms, necessity of NPDES permits to discharge test water into waterways, location of settling ponds, length of time settling ponds will be used, decommissioning of settling ponds and disposition of settled materials. In our opinion the potential impacts of hydrostatic testing can be as significant as oil spills.

③ Page 3-70 - We find the section on oil spill impacts to be inadequate. Methodology of cleaning up spills is not sufficiently addressed, nor are compensation measures for losses to fish and wildlife resources adequately described.

④ Page 3-93 - We consider the spill detection system to be inadequate as far as detecting leaks of up to 4,660 barrels per day. A spill of this magnitude in any major stream or tributary can result in substantial losses. The impacts on small tributary streams from undetected spills can result in long-term losses and be as significant as a major spill. This portion of the statement fails to address this point.

BLM - Northern Tier Project
March 12, 1979
Page 2

The methods of detecting small losses of oil are not described. What is the period of inspections along the pipeline that are designed to detect this type of spill? Alternate methods of detection should be described.

⑤ Alternate Routes - The South Fork of the Coeur d'Alene River was not mentioned as a possible alternate route. For environmental reasons, this route was recommended for consideration by several agencies, environmental groups and individuals at early coordination and consultation meetings. We recommend some comment be made as to why this route was not given consideration.

⑥ Although touched on in several sections of the draft, the decommissioning of the pipeline is not fully nor adequately addressed. The removal of the pipeline is going to create serious impacts on fish and wildlife resources; In many cases, as severe as the construction phase. Creation of an altered environment, by changing forage species in wildlife areas following construction, can serve as an attractant. This creates a situation whereby wildlife species can become dependent and/or enhanced by the habitat change. These losses have not been addressed.

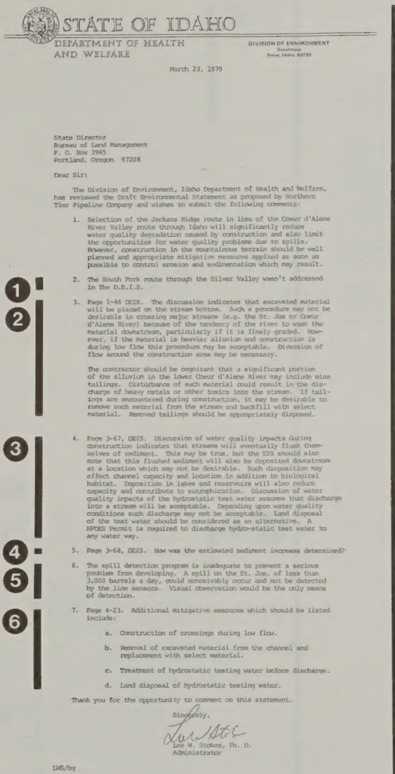
We appreciate the opportunity to comment on this draft and look forward to your inclusion of our recommended changes in the final statement.

Sincerely,

IDAHO DEPARTMENT OF FISH AND GAME

Joseph C. Greenley
Director

C



STATE OF IDAHO
DEPARTMENT OF HEALTH
AND WELFARE
DIVISION OF ENVIRONMENT
Statehouse
Boise, Idaho 83720

March 23, 1979

State Director
Bureau of Land Management
P. O. Box 2965
Portland, Oregon 97208

Dear Sir:

The Division of Environment, Idaho Department of Health and Welfare, has reviewed the Draft Environmental Statement as proposed by Northern Tier Pipeline Company and wishes to submit the following comments:

1. Selection of the Jackass Ridge route in lieu of the Coeur d'Alene River Valley route through Idaho will significantly reduce water quality degradation caused by construction and also limit the opportunities for water quality problems due to spills. However, construction in the mountainous terrain should be well planned and appropriate mitigative measures applied as soon as possible to control erosion and sedimentation which may result.

① 2. The South Fork route through the Silver Valley wasn't addressed in The D.E.I.S.

② 3. Page 1-46 DEIS. The discussion indicates that excavated material will be placed on the stream bottom. Such a procedure may not be desirable in crossing major streams (e.g. the St. Joe or Coeur d'Alene River) because of the tendency of the river to wash the material downstream, particularly if it is finely graded. However, if the material is heavier alluvium and construction is during low flow this procedure may be acceptable. Diversion of flow around the construction area may be necessary.

The contractor should be cognizant that a significant portion of the alluvium in the lower Coeur d'Alene River may include mine tailings. Disturbance of such material could result in the discharge of heavy metals or other toxics into the stream. If tailings are encountered during construction, it may be desirable to remove such material from the stream and backfill with select material. Removed tailings should be appropriately disposed.

③ 4. Page 3-67, DEIS. Discussion of water quality impacts during construction indicates that streams will eventually flush themselves of sediment. This may be true, but the EIS should also note that this flushed sediment will also be deposited downstream at a location which may not be desirable. Such disposition may effect channel capacity and location in addition to biological habitat. Deposition in lakes and reservoirs will also reduce capacity and contribute to eutrophication. Discussion of water quality impacts of the hydrostatic test water assumes that discharge into a stream will be acceptable. Depending upon water quality conditions such discharge may not be acceptable. Land disposal of the test water should be considered as an alternative. A NPDES Permit is required to discharge hydro-static test water to any water way.

④ 5. Page 3-68, DEIS. How was the estimated sediment increase determined?

⑤ 6. The spill detection program is inadequate to prevent a serious problem from developing. A spill on the St. Joe, of less than 3,000 barrels a day, could conceivably occur and not be detected by the line sensors. Visual observation would be the only means of detection.

⑥ 7. Page 4-23. Additional mitigative measures which should be listed include:

   a. Construction of crossings during low flow.
   b. Removal of excavated material from the channel and replacement with select material.
   c. Treatment of hydrostatic testing water before discharge.
   d. Land disposal of hydrostatic testing water.

Thank you for the opportunity to comment on this statement.

Sincerely,

Lee W. Stokes, Ph. D.
Administrator

Comments on NTPC Pipelines EIS

① Page 1-13
It is stated that a leak would be detected and an alarm sounded within two minutes of the incident. How much oil could be lost before the flow was stopped?

② Page 2-78
The last paragraph is slightly misleading. Depending on species, a large portion of the salmon production is from hatcheries and a significant portion of the hatchery production for chinook and steelhead comes from Idaho.

Page 2-79 (3rd paragraph)
It would be more correct to say that the warm water fish comprise the majority of the sports fishery in Eastern Montana, North Dakota, and Minnisota. Warm water fish are important in all the affected states.

③ Page 2-80 (Table 2.1and 2.6-17)
Northern Pike are also present in some of the Lateral Lakes along the Coeur d'Alene River.

④ Page 8-68 (Figure 8.4.2.5-1)

The scale in the legend is incorrect by a factor of six.

Page 8-71

The Jackass Ridge alternative (proposed route) would be much more acceptable since it avoids 24 crossings of a high quality river. The Yellowstone Pipeline Company must repair banks annually to prevent damage to their pipeline. The proposed route would eliminate the necessity of additional bank repairs and impact on the aquatic environment.

LEAGUE OF WOMEN VOTERS OF WASHINGTON

March 30, 1979

Bureau of Land Management
Oregon State Director
Northern Tier Project
Room 1250, Lloyd Building
700 N. E. Multnomah
Portland, Oregon 97232

Re: Draft Environmental Statement on
Crude Oil Transportation System proposed by
Northern Tier Pipeline Company

Dear Sirs:

The League of Women Voters of Washington requests the publication and circulation of an amended DES for the following reasons:

① 1) The Cross-Sound alternative pipeline route announced by the Northern Tier Pipeline Company on March 23 came one week after the conclusion of the BLM public hearings on the DES in the state of Washington. A full risk analysis should be conducted on this now primary route. The worst case analysis should be increased to a throughput of 1.28 million B/D inasmuch as the opportunity for mandatory hookup has been directly enhanced by this route change.

② 2) The Transmountain Pipeline Company proposal for a terminal and storage facility at Low Point, Clallam County has not been analyzed.

3) Title V of Public Law 95-617 implies a full environmental assessment of all proposals. The DES does not adequately analyze the impacts consequent to the Transmountain, Kitimat and Foothills proposals. A thorough analysis of each of these proposals should be available for public review and comment. In our view, a final composite Statement to include all four projects for the purpose of expiditing the permitting process would not meet the requirements of NEPA nor meet the requirements of Title V as a decision-making tool.

4) Impacts on Canadian resources should be identified and evaluated.

③ 5) A comparative net energy analysis of all proposals is fundamental to a national energy decision of this magnitude.

In addition, the League requests incorporation of the findings of:

④ 1) DEPARTMENT OF ENERGY. Petroleum Supply Alternatives for the Northern Tier and Inland States Through the Year 2000. February 21, 1979.

⑤ 2) NOAA. Circulation in the Strait of Juan de Fuca: Some Recent Oceanographic Observations. June, 1978.

It is our opinion that this Environmental Statement does not meet the CEQ guidelines. Resource inventories are inadequate throughout the document. Impacts are not evaluated and quantified. Mitigating measures are without substance.

1406 - 18th AVENUE, SEATTLE, WASHINGTON 98122 • (206) 329-4646

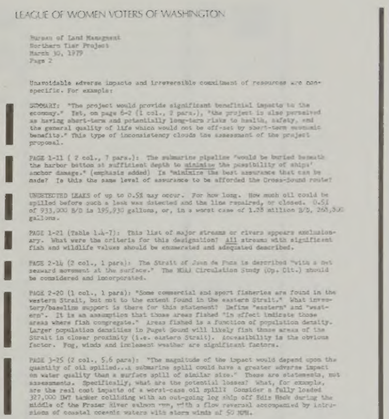
CONT.



LEAGUE OF WOMEN VOTERS OF WASHINGTON

Bureau of Land Management
Northern Tier Project
March 30, 1979
Page 2

Unavoidable adverse impacts and irreversible commitment of resources are non-specific. For example:

⑥ SUMMARY: "The project would provide significant beneficial impacts to the economy." Yet, on page 6-2 (1 col., 2 para.), "the project is also perceived as having short-term and potentially long-term risks to health, safety, and the general quality of life which would not be off-set by short-term economic benefits." This type of inconsistency clouds the assessment of the project proposal.

⑦ PAGE 1-11 ( 2 col., 7 para.): The submarine pipeline "would be buried beneath the harbor bottom at sufficient depth to minimize the possibility of ships' anchor damage." (emphasis added) Is "minimize the best assurance that can be made? Is this the same level of assurance to be afforded the Cross-Sound route?

⑧ UNDETECTED LEAKS of up to 0.5% may occur. For how long. How much oil could be spilled before such a leak was detected and the line repaired, or closed. 0.5% of 933,000 B/D is 195,930 gallons, or, in a worst case of 1.28 million B/D, 268,800 gallons.

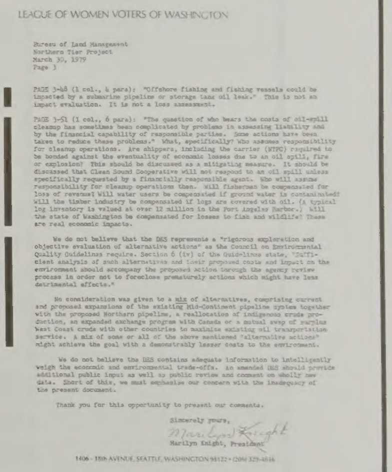
⑨ PAGE 1-21 (Table 1.4-7): This list of major streams or rivers appears exclusionary. What were the criteria for this designation? All streams with significant fish and wildlife values should be enumerated and adequated described.

⑩ PAGE 2-14 (2 col., 1 para): The Strait of Juan de Fuca is described "with a net seaward movement at the surface." The NOAA Circulation Study (Op. Cit.) should be considered and incorporated.

⑪ PAGE 2-20 (1 col., 1 para): "Some commercial and sport fisheries are found in the western Strait, but not to the extent found in the eastern Strait." What inventory/baseline support is there for this statement? Define "eastern" and "western". It is an assumption that those areas fished "in effect indicate those areas where fish congregate." Areas fished is a function of population density. Larger population densities in Puget Sound will likely fish those areas of the Strait in closer proximity (i.e. eastern Strait). Accessibility is the obvious factor. Fog, winds and inclement weather are significant factors.

⑫ PAGE 3-25 (2 col., 5,6 para): "The magnitude of the impact would depend upon the quantity of oil spilled...a submarine spill could have a greater adverse impact on water quality than a surface spill of similar size." These are statements, not assessments. Specifically, what are the potential losses? What, for example, are the real cost impacts of a worst-case oil spill? Consider a fully loaded 327,000 DWT tanker colliding with an out-going log ship off Ediz Hook during the middle of the Fraser River salmon run, with a flow reversal accompanied by intrusions of coastal oceanic waters with storm winds of 50 MPH.

---



LEAGUE OF WOMEN VOTERS OF WASHINGTON

Bureau of Land Management
Northern Tier Project
March 30, 1979
Page 3

⑬ PAGE 3-48 (1 col., 4 para): "Offshore fishing and fishing vessels could be impacted by a submarine pipeline or storage tank oil leak." This is not an impact evaluation. It is not a loss assessment.

⑭ PAGE 3-51 (1 col., 6 para): "The question of who bears the costs of oil-spill cleanup has sometimes been complicated by problems in assessing liability and by the financial capability of responsible parties. Some actions have been taken to reduce these problems." What, specifically? Who assumes responsibility for cleanup operations. Are shippers, including the carrier (NTPC) required to be bonded against the eventuality of economic losses due to an oil spill, fire or explosion? This should be discussed as a mitigating measure. It should be discussed that Clean Sound Cooperative will not respond to an oil spill unless specifically requested by a financially responsible agent. Who will assume responsibility for cleanup operations then. Will fishermen be compensated for loss of revenue? Will water users be compensated if ground water is contaminated? Will the timber industry be compensated if logs are covered with oil. (A typical log inventory is valued at over 12 million in the Port Angeles Harbor.) Will the state of Washington be compensated for losses to fish and wildlife? These are real economic impacts.

⑮ We do not believe that the DES represents a "rigorous exploration and objective evaluation of alternative actions" as the Council on Environmental Quality Guidelines require. Section 6 (iv) of the Guidelines state, "Sufficient analysis of such alternatives and their proposed costs and impact on the environment should accompany the proposed action through the agency review process in order not to foreclose prematurely actions which might have less detrimental effects."

No consideration was given to a mix of alternatives, comprising current and proposed expansions of the existing Mid-Continent pipeline system together with the proposed Northern pipeline, a reallocation of indigenous crude production, an expanded exchange program with Canada or a mutual swap of surplus West Coast crude with other countries to maximize existing oil transportation service. A mix of some or all of the above mentioned "alternative actions" might achieve the goal with a demonstrably lesser costs to the environment.

We do not believe the DES contains adequate information to intelligently weigh the economic and environmental trade-offs. An amended DES should provide additional public input as well as public review and comment on wholly new data. Short of this, we must emphasize our concern with the inadequacy of the present document.

Thank you for this opportunity to present our comments.

Sincerely yours,

Marilyn Knight
Marilyn Knight, President

Northern Tier Project
Room 1250, Lloyd Building
700 N.E. Multnomah
Portland, Oregon 97232

Dear Sirs:

There are several points we would like to make regarding Northern Tier Pipeline:

① 1) As residents of Sanders County, Montana and Prospect Creek we find your draft Environmental Impact Statement (EIS) grossly inadequate in regard to this area. As a utilities corridor this area is essentially glutted when you consider the presence of Yellowstone Pipeline and five major powerlines. If Colstrip Kines 3 and 4 in Eastern Montana are approved, there will be at least two more major powerlines through this area. Surely the disruption of such a fragile streambed environment as Prospect Creek, and crossing such a large river as the Clark's Fork at least five times should rate more study than the skimpy paragraph reflects in the EIS.

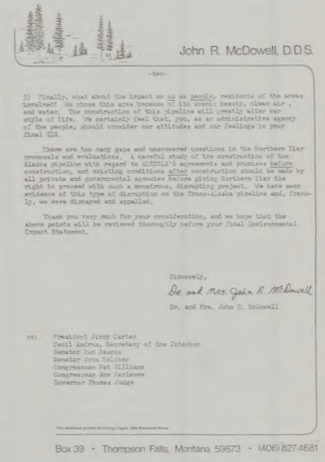
② 2) We question Northern Tier's proposal for a 90 foot temporary and a 75 foot permanent easement for this pipeline, when you consider that the Trans-Alaska pipeline with all of its special environmental problems required only a 54 foot easement.

③ 3) We understand that one of the reasons for building this pipeline is to transport surplus Alaska Crude oil from the West coast to refineries in the Midwest that can handle this high sulfur content crude oil. Would it not be more practical to retrofit West Coast refineries, enabling them to process the straight "sour" Alaska crude without mixing it with a "sweet" crude such as Indonesian crude oil?

④ 4) As an alternative route to Prospect Creek, the local Forest Service district ranger, Tom Squire has proposed using the existing Tri-Creek fire break from Thompson Pass (on Montana-Idaho border) over Driveway Peak ridge. This area is already cleared and maintained and does not threaten the ecological stability of the area as much as the Prospect Creek route does.

Box 39 • Thompson Falls, Montana 59873 • (406) 827-4681

---



John R. McDowell, D.D.S.

-two-

⑤ 5) Finally, what about the impact on us as people, residents of the areas involved? We chose this area because of its scenic beauty, clean air, and water. The construction of this pipeline will greatly alter our style of life. We certainly feel that, you, as an administrative agency of the people, should consider our attitudes and our feelings in your final EIS.

There are too many gaps and unanswered questions in the Northern Tier proposals and evaluations. A careful study of the construction of the Alaska pipeline with regard to ALYESKA'S agreements and promises before construction, and existing conditions after construction should be made by all private and governmental agencies before giving Northern Tier the right to proceed with such a monstrous, disrupting project. We have seen evidence of this type of disruption on the Trans-Alaska pipeline and, frankly, we were dismayed and appalled.

Thank you very much for your consideration, and we hope that the above points will be reviewed thoroughly before your final Environmental Impact Statement.

Sincerely,

Dr. and Mrs. John R. McDowell
Dr. and Mrs. John R. McDowell

**116**

[illegible]

[illegible] review covers that portion of the Northern Tier Pipeline. The alternate route [illegible] between mile posts 46 and 50. General area known as [illegible] Creek to [illegible] Creek and within Township [illegible] and Range [illegible], [illegible].

General Notes: The EIS is inadequate for the alternate route and does not meet the NEPA law requirements because of major omissions. The information is incomplete and not adequate to make a decision on a general route let alone a final decision.

Many items are left out or only inferred to. The EIS is difficult to read and to pick out detail. One has the impression of reviewing a Corps of Engineer or EPA proposal where the need and details of a re-regulating dam or need for a second powerline for reliability are easily dismissed. Consequently we are not certain what is planned.

There is in effect a real lack of trust because of what is left unsaid. Because of the limited data it is difficult for us to review and comment on impacts since impacts are not displayed. Following are specific comments.

① 1. PUMP STATIONS. No locations are shown. We were unable to determine the size of the installations. No details on service facilities i.e. roads, powerlines, telephone and other associated developments. It appears that larger quantities of electricity will be needed which includes a major powerline. Visual controls are not mentioned or available in the EIS for specific locations.

② 2. [illegible]. [illegible] the original route was based on [illegible]. The proposed alternative is routed through several subdivisions. Most of the houses have been built in the last five years. Actually the aerial photo strips may be several years old and does not reflect the current situation.

There is no discussion on why the route went through subdivisions when other alternatives were available. No indication of the selection process and short versus long term impacts. The statistics on population and developments are not up-to-date. The costs of obtaining R/W, replacing fences, crossing roads and disturbing access are not considered.

Of concern to land owners is the deterioration of land value and particularly the loss of selection of siting for buildings because of R/W restrictions. Many owners are in the process of or are considering splitting tracts into five acre lots. The pipeline reduces their options and can result in a financial loss. These opinions are based on information from realtors and land appraisers who live in the area.

③ 3. SOILS. The proposed route mostly lies in clay, clay-silt or clay containing soils i.e. [illegible], Lake Missoula Sediments, etc. There are particular problems associated with construction, stability, rehabilitation, maintenance, etc. that make these soils less desirable. Particularly when gravelly soils are nearby. Construction in Lake Missoula sediments can also interrupt aquifers and change the flow characteristics which could result in slumping or disturbance of existing water developments.

④ [illegible] the route until [illegible] Northern Tier. While these are two separate actions there nevertheless is a potential relationship that can cause hardship. The continuing harassment of people in this area, and the threat to social well being is real. It would appear that the EIS's prepared by the Interior Department would have some correlation particularly since they are being presented at the same time and are using the same [illegible].

**CONT**

⑤ 5. [illegible]. [illegible] proposed is within the [illegible] Lineament, a regional tectonic feature [illegible] called the Lewis and Clark fault zone or [illegible]. The EIS does not indicate anything in this area yet shocks of [illegible] on the Richter scale occurred in the [illegible] vicinity in 1975 along with numerous aftershocks.

The gravelly alluvium is better for siting the pipeline. The gravels generally would be less affected by seismic activity than the finer silts and clays on the benches.

[illegible]. Local employment is needed and [illegible] that will reduce the social and economic impacts are available.

⑥ [illegible]. There are no assurances in the EIS that land-owners rights will be protected in the event of construction problems or in the event that the pipeline leaks. Experience indicates that [illegible] to correct damages. The [illegible]

⑦ [illegible]. This is an [illegible] and the amount [illegible] be substantial — estimated at over 300,000 gallons. The proposed location would not only harm the immediate area but it is above a major irrigation system (Frenchtown Ditch) that would pollute thousands of acres.

These are some of our concerns. Since the EIS had inadequate coverage we would like the opportunity to comment in detail. Please address your correspondence to the Association President, Mr. Randall [illegible], Box 156, Frenchtown, Montana 59834.

Bureau of Land Management
Room 1250, Lloyd Building
700 NE Multnomah
Portland, Oregon 97232

Dear Sir;

I understand that your organization has been made the "lead Agency" for the proposed Northern Tier Pipeline. I have wanted to contact someone ever since I read the recent newspaper article indicating a decision had been reached to utilize the alternate route across Whidbey Island, Camano Island into Stanwood. How could a firm decision be reached without any public hearings in the areas directly involved? It seems to have been a capricious and inconsiderate determination, and I , for one, am most disturbed!

Northern Tier had announced that they would have representives meet with the concerned citizens of Island County on February 27th. When the meeting convened, the "representives" proved to be a consultant firm, hired to determine what kind of questions we would like to have answered, but they were not able (or permitted) to provide any answers. To me such a meeting was a waste of time, both ours and theirs. When pressed about an Environmential Impact Statement, the response indicated that one had been prepared, but that the Whidbey-Camano Crossing had been treated only as an alternate (and as incidental). Can such an EIS be considered as reasonable and sufficent in the light of the decision to use the alternate? We had asked for an opportunity to review the prepared statement and were advised that copies would be provided, but as of this date we have not heard a word, and one gets the impression that we are not likly too.

It is absolutely essential that our questions be answered. Northern Tier can hardly expect us to show any consideration if they refuse to show us even the slightest courtesy! We want to know what precautions will be exercised during and after construction; who will provide the perpetual maintenance of the right of way etc., etc. Why, indeed, must the line be built when no government seems willing to file a "Certificate of Need"?

One gets the feeling that Northern Tier has absolutely no respect or concern for the people of Island County, and are ready to ride rough shod over anyone. The fiasco of the February 27th meeting and the casual, even shabby treatment demonstrated towards us is miserable public relations and cannot be tolerated.

As the lead agency what would be your suggested action for the local citizens to take in order to obtain satisfaction? We appreciate your concern.

Very truly yours,

Walter I. Lewis

Plaza, North Dakota
March 26, 1979

Oregon State Office
Northern Tier Project
729 N.E. Oregon St.
Portland, Oregon 97208

Gentlemen:

As a result of the Northern Tier Project Hearing in Minot, North Dakota, we would like to add this information to the minutes of that meeting.

First, we realize there is need for the pipeline.

Secondly, we have several concerns:

① 1) That the construction of this line does not destroy farm trees and shelterbelts. In the dry land farming area of North Dakota, trees are often difficult to raise and slow to mature. After telling us they would transplant the evergreens standing within their right-of-way, Portal Pipeline crews bulldozed all the evergreen trees within their path, and by movement of their equipment beyond the right-of-way, they killed more trees unnecessarily.

② 2) From a statement made at the Minot Hearing, it is proposed to cover the line by three feet of soil. In fact this should be increased to at least five feet of soil. The alkaline seep is ruining some of my land for production purposes. To restore this land to production it is necessary to plow the soil to a depth of four feet. By turning under the defective top soil deeply, fresh soil is brought to the surface for agricultural use. You can see that the pipeline would need to be at least one foot below the land being worked for alkali.

3) Again, by statements made at the Minot Hearing, in this area Northern Tier will follow rather closely the line used by the present Portal Pipeline. The Portal line cuts our farm for a mile east and west, and runs within approximately 100 feet of the door of my home. It is closer to some of my other buildings.

We realize the importance of this proposed pipeline. But with a gas line cutting the south part of our land and Portal just beyond our trees, the Northern Tier would be the third line cutting our property where we are trying to produce food to feed the nation and the world.

We will appreciate your consideration in the placing of this line.

Respectfully,
Lloyd R. Jones and
Caroline Jones

Re: Air Pollution Impact of Proposed Northern Tier Pipeline

Attn: Ron Sundell

Dear Sir

This letter is to protest the inadequacy of the air pollution monitoring studies being conducted by Northern Tier Pipeline Co. and to protest the timing of initiation of these studies. Northern Tier Pipeline co., using the data collected by a supposedly independent engineering firm, is gathering air pollution data to be presented as evidence of the air quality in the Port Angeles area. This letter is in portest on the inadequacy of the sites of monitoring and the timing at which this data collection began.

One of the important areas of our city that has been overlooked in air pollution discussions is the Olympic Memorial Hospital. This is the only major hospital on the North Olympic Peninsula and sits facing the open bluff directly across the water from the proposed oil port terminal. The distance between the oil port terminal and the hospital is between on and one and a half miles. The hospital also is located between the two major pulp and paper mills in the city and is already subject ot a large amount of air pollution from these two industrial sites. This summer there was one day when the entire north side of the hospital rooms had to be shut down and the patients moved out because of high air pollution from these mills. Air pollution is a chonically recurrent problem in our hospital. No monitoring devices of air pollution have ever been taken from the hospital grounds. I am suggesting that air quality monitoring equipment be located on the hosptial grounds, preferrably the roof of the hospital, to gather valuable data concerning the air pollution levels while the mills are operating.

The air quality monitoring stations which have been erected and are being monitored by the consulting firm which is working for Northern Tier began collecting air pollution data in this area one week after the local pulp and paper mills shut down on strike. The pulp and paper mills of this area are the major contributors to air pollution and the air pollution locally is severe during the months of August through October. In July of 1978, both Crown Zellerbach and the ITT Rayonier mills shut down and remained on strike during the entire fall and winter months. According to the management of these mills during August, September and October the mills were being operated by management at approximately 20 to 30% usual capacity. During the second three monhths of the strike in November, December and January the mill capacity was then increased to close to its usual output. The worst three months for air pollution in Port Angeles is August, September and October. Routinely there is little air pollution in November, December and January because of brisk westerly winds.

I feel the coincidence of the initiation of data gathering corresponding to the closing of the mills in the area makes data gathering thus far totally irrelevent. I would porpose air pollution data be gathered while the mills are in full operation with particular attention being paid to the monhts of August through October since this is our heaviest pollution time. I would also suggest that a monitoring station be erected on the grounds of Olympic Memorial Hospital.

I would appreciate an explanation as to why the importance of air pollution in the vicinity of the hospital has been totally ignored.

Sincerely yours

John R. Mather

Star Route
Huson, Montana 59846

March 26, 1979

BLM-Northern Tier Project
Room 1050, Lloyd Building
700 N. E. Multnomah Street
Portland, Oregon 97232

Gentlemen:

Enclosed you will find our comments and questions relating to the draft Environmental Impact Statement issued by your agency for the proposed Northern Tier Pipeline project.

As detailed in the section GENERAL CONSIDERATIONS, we feel the proposal fails to address the following questions:

-The fact that two thirds of the proposed route falls on private land and yet the opinions of landowners have not been assessed.

-Establishment of an energy corridor without critical assessment of the cumulative effects of such multiple use.

-Appropriate and accurate studies of the water resources of the areas involved in corridor establishment for the pipeline.

-The need for independent quality control before, during and after construction.

-Identification and detailed assessment of all viable alternatives to the project proposed.

-The very obvious lack of time which is critical for proper pre-impact, construction impact, and post-construction impact studies.

We wish to express grave concern with the fact that this draft Environmental Impact Statement is both outdated and inappropriate to the pipeline route as presently proposed by Northern Tier.

Thank you for the opportunity to express our concerns.

VALLEYS PRESERVATION COUNCIL

Jan Rippe, Chairman

Rene Grauer, ViceChairman

JR/RG:eb
Enclosure as above.

COMMENTS ON DRAFT ENVIRONMENTAL STATEMENT
CRUDE OIL TRANSPORTATION SYSTEM
AS PROPOSED BY THE NORTHERN TIER PIPELINE COMPANY

---

① p.1-5 Projected demand should be estimated from more than one source. Demography and economics should be included.

p.1-8 Canadian supplies do exist after 1980. Document the decrease in production of the Northwest. Again, estimated shortfalls are based on what?

② p.1-16 Section on Pipeline System. The pipeline route has been altered so many times that the entire DES needs revision.

p.1-18, 1-23 Site specific river crossing techniques should be outlined.

p.1-24 Pipeline. Nature and location of scraper traps should be specified. Mainline valve locations are not accurate because of route changes in western Montana.

p.1-35 As stated in the DES, field inspection and quality control will be monitored by NTPC. This is totally unacceptable, obviously, due to vestment of interest. Independent inspectors are absolutely necessary.

p.1-38 Specific storage yards and facilities are not mentioned. In particular, what would be the impact of these storage areas? Where would the Ninemile stockpile be?

p.1-41 Who estimates construction damages? How are these damages compensated? Damages to public lands are not addressed.

Clear definition of "access to the pipeline" must be given.

②a Justification for a 75-foot easement must be made.

p.1-43 An actual photograph of a construction spread and not an artist's conception is necessary.

p.1-44 How are forests logged? Slash removed? How is soil which has been "stabilized to support heavy equipment" restored? How are access roads constructed for equipment moving restored? Alteration of existing roads is not addressed.

p.1-44 Who would insure integrity and closure of gates for livestock control? Who will monitor double-ditching? Will there be air pollution from external coating process? What type of coating will be used?

If the ground is "compacted to its original state" then where does the "crown" of excess material go?

p.1-46 Would there be settling ponds for dredging operations? Would there be spoil piles and streambank alterations?

"Riprap and other materials..." is in direct contradiction to statement #22, p.1-58.

"Major stream crossings would be scheduled in a three month period..." is in contradiction with the proposed construction schedule.

What is a "major stream"?

What is the authority and qualifications of the "environmental inspector representing NTP"?

②b p.1-47 The whole hydrostatic testing section is completely inadequate. For example:
1) How much water is required?
2) The additives to the water are not specified.
3) Discharge water erosion prevention is not mentioned.

CONT.

②b
4) Surface water contamination is inescapable. If much of the available water is used, the whole supply will be contaminated.
5) How will test water be routed from its origin to the pipeline? Does this come under "access" (see p.1-41)?
6) The removal of test water from creeks and rivers will be in direct violation of Montana and federal water rights laws. This conflict is inescapable and must be resolved.

② "The purpose of the cleanup and restoration operation would be to return the right of way and other areas affected by construction to their original conditions where practical..." Define "where practical". Departure from practicality must be site specific.

The contour of the soil is returned but what about the soil itself?

What is a "pipeline marker suitable for observation from the air"?

How about revegetation plans for private landowners?

p.1-50 Abandonment and Disposal. Where would flush water go? If local water is used, how about water rights?

p.1-55 "Minor spills generally cause minimal impacts" is really meaningless unless actual gallons are specified. What is the difference between a spill and a leak? Possibility of leak detection by EROS or ERTS satellite should be mentioned.

p.1-56 Measures Proposed for Environmental Protection.

#4 One inspector per spread is not sufficient. Inspectors should be independent of NTPC and should have stop work authority.

#6 "Any unsuitable and surplus material...will be disposed of on the site whenever possible" really means that any excess material will be dumped whenever and wherever it is convenient for the contractor.

#9 The Ninemile Valley is an unrecoverable resource as is Siegel Pass, and the route should be adjusted.

#11 Dust producing areas should also be watered in rural areas such as the Ninemile Valley.

#13 Any settling pond sites required should be specified fully in the final EIS.

#15 The Ninemile Valley is a critical watershed and should be studied in greater detail.

#17 Who would decide what is "reasonable project economics" when routing river and stream crossings?

p.1-57 #21 Stream hydrolics and geotechnical studies should be done in the EIS and should be site specific.

#22 There is no way that the natural water flow will be unaffected by the pipeline.

#23 In view of the magnitude of this pipeline, should the engineering specs and requirements be examined to see if they are really adequate?

#25 The fact that Northern Tier would assist only in applying for federal and/or state aid to mitigate any adverse impacts is a gross insult to the taxpayer and individual landowner! Northern Tier should be liable for all damages whether direct or indirect, not the taxpayer.

#26 Northern Tier's plans to utilize local labor and to arrange for temporary housing is just worthless public relations rhetoric. Construction realities would bear this out. What provisions would be made for recreational vehicles and campers--especially on the National Forest camp areas?

#27 The ballasting will be determined by safety not by the vicinity of the tanker to the harbor.

③ p.2-47 "Mean annual precipitation ranges between 20 and 40" in mountainous areas of northern Idaho and western Montana depending on elevation." Mean annual precipitation for Ninemile-Sixmile areas to be crossed by the pipeline is less than 20" (Multiple Use Plan, Ninemile-Mill Planning Unit, U.S.F.S., 1976). This must be kept in mind particularly as regards revegetation. Likewise, the mean monthly temperatures quoted are not applicable to this area and are in need of correction to reflect the severeextremes to be faced by seedlings.

④ p.2-48 "Windblown dust sometimes causes high particulate readings in rural areas." The Missoula County Board of Health can verify the severity of this condition in the Ninemile-Sixmile area. And yet, p.4-2 under 4.2 Air Quality, "No significant mitigating measures identified." ?????

⑤ p.2-50 "Gentle to steep slopes make them (i.e. soils of northern Rocky Mts. physiographic region) moderately to highly susceptible to water erosion." How will this be prevented? The pipeline will cross 15 streams in this valley with the danger of disrupted water flow. Will original stream gradients be maintained at stream crossings after construction thereby preventing severe erosional areas from starting and/or accentuating?

⑥ p.2-95 The on-site surveys for threatened and endangered species should be done before the final EIS and certainly before issuance of permits. Remember the snail darter! Specific attention needs to be given the bald eagle and peregrine falcon.

⑦ p.2-98 The Ninemile area is every bit as important as the Clark Fork River valley and for the same reasons. It is rich in diverse wildlife resources. Specifically, the Ninemile-Sixmile valleys are prime elk and deer wintering areas.

⑧ p.2-103 There are many logging and mining camps, as well as Indian summer campsites, throughout the Ninemile-Sixmile area.

The archaeological surveys should be conducted before pipeline permits are let! Table 2.1.2.10-1 should be amended to include the areas currently proposed by NTPC.

⑨ p.2-116 The Ninemile Valley is again neglected. Visual impact due to erosion and scars would be very high.

⑩ p.2-120 Table 2-1.2.12-6 must be updated. Many acres of farmland will be crossed.

⑪ p.2-122 Table 2.1.2.12-7 should include Frenchtown, a rural center.

⑫ p.2-124 Are there any pristine or relic vegetative communities along the altered route? If so, they should be considered.

CONT.

⑬ p.2-139 Ninemile Creek is extensively fished.

⑭ p.2-143 Table 2.1.2.15-5. Camper space must be assessed as many pipeline construction workers camp.

⑮ p.2-151 The housing of workers in Spread 5 will not be in Missoula. NTPC seems to think that workers will be housed in Plains and Thompson Falls. In fact many of them will camp along the route. This is also true of other spreads. This whole section should address the impacts to local camping areas. Experience along the Alaska pipeline proves this out.

⑯ p.2-153 "Police protection is generally considered adequate for present conditions." What about construction conditions?

The section on social conditions is inadequately researched and begs the question. Elk and deer cannot be asked for their preferences, but people can! Vast monetary and personnel resources have been spent on assessment of flora and fauna. The population along the pipeline route is a major resource which has not been properly studied.

There are no economic benefits to local populations. Indeed those unfortunate enough to have the pipeline on their property will lose economically.

⑰ p.2-160 Montana. A thorough study of the impact on the water structure of Ninemile and Sixmile valleys is necessary as the water structure is quite complex.

⑱ p.2-163 Table 2.2/2.13-2 is meaningless and the reason for its inclusion in the DES must be explained.

⑲ p.3-56, 3-57 Unpaved roads are as important as a fugitive dust source as is the actual construction site. This should be made clear.

⑳ p.3-59 Summary impacts to physical geology will be large in several places in ~~[illegible]~~ River crossings, places of potential slides (such as Siegel Pass) will suffer significant impact due to construction of ~~[illegible]~~.

Blocking or diverting of small surface drainages will be, in most cases, permanent unless the landholder corrects them.

㉑ p.3-60 The entire route through the Ninemile valley is right on top of an old, extensive fault. Any fault motion might cause a severe rupture.

㉒ p.3-61 Liquefaction studies need to be carried out along the alternate route. Slope instabilities of severe proportion are likely in the Siegel Pass and Frenchtown areas.

㉓ p.3-62 Mineral Resources. The entire Ninemile area is covered with placer claims, several of which are active. The proposed pipeline would traverse these resources.

Site specific disposal of rock material unsuitable for backfill must be addressed--especially in the Siegel Pass area!!

㉔ p.3-65 Spills. Aerial inspection every two weeks is not adequate for the potential of oil spills which could occur without being electronically detected. This is especially true during winter months and for inaccessible areas.

Erosion Losses. On page 2-116 manmade intrusions such as pipelines and powerlines would cause "erosion and scars", which contradicts the assumption on page 3-65 that "erosion loss would be normal..."

㉕ p.3-67 Aquatic Resources. "Ground water flow characteristics would not be significantly affected by construction of pipeline." This is not true and this should be properly addressed.

Hydrostatic testing procedures are not adequately explained in construction section of Chapter One. Adequate protection of the environment from contaminated hydrostatic water will not be possible if there is no independent inspection system.

Nothing is said in this section about the source of the water for hydrostatic testing.

Oil spill probability statistics are really meaningless because a statistic is not an impact.

㉖ p.3-70 Table 3.2.6-2, Maximum Potential Oil Spill. This table should include Ninemile, Sixmile, Houle, Roman, and Mill Creeks, as well as all the 21 tributaries to Ninemile Creek.

㉗ p.3-72 "There would be no significant impact resulting from test water discharge." This would only be true if test water is properly treated--will it be?

㉘ p.3-75 A site specific study of the accumulative effects of siltation resulting from construction must be done--especially for the Ninemile drainage.

㉙ p.3-80 Terrestrial Vegetation. The logging aspects of the construction process has not been realistically assessed especially on 2,835 acres of forest habitat in a 90-foot corridor. For example, how would slash be properly disposed of? How would merchantable timber be removed from the corridor?

"Associated with this loss of dominant overstory vegetation would be an expected increase in shrubs, grasses, and sedges, within the first year following construction." Not necessarily considering the disturbance to the area. Source of information?

㉚ p.3-84 Maintenance of right of way in general is not adequately addressed, in particular shrub and weed control. What type of "chemical control at approximately 5-year intervals" is planned for maintaining the corridor?

㉛ p.3-93 Operation Phase. No mention is made of increased hunting pressure resulting from a long straight corridor which would be easily accessible.

㉜ p.3-96 Visual Impacts Construction Phase. The assumption that "construction would be carried out in an orderly, technically proficient... manner" is not a realistic appraisal of this construction project. Therefore the whole visual analysis assumption is not relevant.

㉝ p.3-97 Support Facilities. All impacts of the construction of microwave and power facilities antecedent to the pipeline have not been considered at all in the text of the DES. These are major impacts and require adequate study.

㉞ p.3-101 A 30-by-40-foot cleared fenced area for block valves is not mentioned other than as a visual impact. These areas would be a major and diverse impact which should be considered in other sections of the DES.

CONT.

㉟ p.3-102 The spoils disposal problem has not been properly addressed. In addition there is the question of revegetation of spoils which tend to be sterile in nature.

㊱ p.3-103 Variable right of way discussed in this section needs to be considered in other sections of DES.

Table 3.2.12-1 Estimated Direct Impacts of Construction (in Acres). This table does not discuss indirect impacts such as access roads, spoils piles, material sites, etc.

Losses in agricultural production would be significant to individual producers especially in this area.

Will farmland designation be mapped before construction?

㊲ p.3-104 On revegetation of right of way, will there be weed control in range areas?

㊳ p.3-106 Where is Table 3.2.12-3 for indirect acreages affected on powerline corridors?

The Wilderness section is very confusing. How could there be any impacts on a wilderness since right of way would be denied through wilderness areas?

㊴ p.3-108 Road and Highway Traffic. Road damage would be significant on county roads, especially 410 commuting workers and 50 truck deliveries daily.

Partial road closures will not deal with construction realities on our rural roads.

㊵ p.3-109 That temporary access roads would be less than one mile in length is an unwarranted assumption, especially in forested and more inaccessible areas.

㊶ p.3-110 Table 3.2.13-1 New electrical system facilities required if the proposal is implemented. Because of the amount of acreage involved would not a separate EIS be required to assess impacts?

㊷ p.3-111 "Possible construction of new communications facilities is therefore not likely to cause significant impacts." This is in direct conflict with visual impact analysis in earlier part of this section.

The implementation of a cathodic protection system is not discussed. Does this involve above ground installations?

㊸ p.3-118 Experience shows that heavy use of either designated or undesignated campgrounds by constructions workers causes severe impaction.

㊹ p.3-119 Heavy housing impacts will also occur in western Montana.

㊺ "The addition of pipeline property to the tax base would increase property tax revenue and/or reduce effective levy rates." This statement does not consider increased costs to the taxpayer, especially those caused by damage to roads.

The general economic methodology used in the DES is totally unrealistic.

㊻ p.3-121 Housing. The previous section on recreation and campground use should consider statistics of Construction Worker Profile.

We question the statement that construction workers will not bring their own children.

㊼ p.3-124 Fire Protection. Rural volunteer fire departments will not necessarily respond to construction site fires. Rural volunteer fire departments respond primarily to dwelling fires. They are not trained or equipped for construction fires.

㊽ p.3-125 (Missing heading)

Section with heading missing is probably the most important section especially since it deals with people and the implications of the eminent domain law. No attention is paid to depreciation of property values which is certainly a major economic impact. This section should be thoroughly reevaluated.

㊾ p.4-2 "Revegetation of borrow areas is considered standard practice and was assumed in impact analysis reported in chapter 3." Does this apply to all borrow areas, or just U.S.F.S. areas? What are the specifics of the "revegetation" to be applied?

Re additional measure item 1.--What soil impact-reducing measures will be applied to all lands crossed?
Re additional measure item 3.--Where will the "offsite disposal" areas be located?
Re additional measure item 4.--From where will be water be drawn to water "after construction until vegetation is established"?

"Avoidance of known areas of potential slope failure is considered standard practice, and was assumed in the impact analysis reported in chapter 3." But, p.8-77, "Slope instability has been identified near Siegel Mtn...." and "Either of these geologic hazards (i.e. slope instability or liquefaction problems) could result in pipeline ruptures."

p.4-4 What revegetative measures will be taken on land to be crossed by the corridor given that this is an area of low precipitation (less than 20"/year), temperature extremes, and potential soil degradation?

"The NTPC proposes to locate the pipeline and related facilities to avoid vulnerable wildlife habitats." But, p.8-79 (re Ninemile Creek), "Impacts from additional removal of winter range by construction of the pipeline would increase dependence on the already heavily used winter range on national forests."
Depending on the final route chosen, the pipeline corridor has the potential of crossing up to two-thirds of key deer-elk winter range in the Ninemile-Mill Planning Unit (Fig. 14, Multiple Use Plan, Ninemile-Mill Planning Unit, U.S.F.S., 1976). There is also extreme danger of destroying areas of important summer forage for both wildlife and domestic livestock.

㊿ p.5-16 Construction impacts on ground water would be permanent in some areas and not temporary, as stated in the DES. This should be further researched.

(51) p.5-17 Construction schedules will necessitate stream crossing at periods other than low water which would result in serious sedimentation, etc.

(52) p.5-18 Table 5.2.8-1 Unavoidable Impacts on Vegetation. Mitigating measures could only be assured if environmental inspector is independent and has stop work authority.

(53) p.5-20 Visual Impacts. Siegel Pass and Ninemile segment of pipeline will result in a serious visual scar.

This project would not be a nuisance - to landowners in this area but rather it would be a disaster!

120 CONT

(54) p.5-21 5.2.1.3:

1) Rather than "congestion" we would have traffic hazards along many parts of rural roads.

2) Truck traffic will (not might) cause significant road damage.

(55) p.5-22 Recreation Resources. Accessibility of corridor to hunting pressure would be impact on wildlife.

(56) p.5-23 Short term increases in population should also include western Montana as critical impacted areas.

Table 5.2-15-1.
Fiscal Capacity - Expenditures of local governments may not be compensated even after construction phase.

Loss of revenue to individual landowners is neglected. For the individual landowner pipeline construction is not a short term nuisance.

(57) p.6-2 "Once a utility corridor is established it tends to attract additional new utilities." The fact that this area of Montana could become an enormous energy corridor should be thoroughly assessed especially with regard to the cumulative effects.

The discussion of the abandonment phase of this project is pointless since a multible use corridor will certainly occur.

(58) p.6-3 The section on local adverse impacts does not consider long term property devaluation on private land.

"Minor pipeline leaks are expected to occur quite frequently throughout the life of the project."
What is a "minor" pipeline leak? If it's undetectable by the automatic leak detection system it could be up to 3 to 4 thousand bpd (p.1-31). How many days before detection?

(59) p.7-4 How can an "irretrievable change" be short term?

(60) p.8-77 "Construction of this alternate route segment would have relatively minor topographic impacts, primarily landscape changes and temporary drainage alteration." The following comments are addressed to the aforementioned "temporary drainage alteration":

-The most adverse impact of pipeline construction on aquatic resources would be in clearing and maintaining a 75' right-of-way. There is no question this would increase water temperatures. This subject is not addressed in the draft EIS. Removal of riparian vegetation would compound this problem, and would increase suspended sediments.

(61) -It is important to maintain original stream gradient at crossings after construction. This would help prevent stream blockage for migrating fish, prevent severe deposition or erosional areas from starting and accentuating. This matter was not discussed in the draft EIS.

(62) -Test water could be a major problem if taken from Ninemile Creek. Six cfs would probably dewater Ninemile Creek in low flow periods (U.S.G.S. Water Resources shows a mean minimum discharge of only 12 cfs for August 1977, for example). Also if this water was discharged into Ninemile Creek it could have serious impacts, particularly in late summer. Would pH be readjusted? What bacteriacide would be used, what concentration, and what impacts would this have on the stream? This subject has not be adequately addressed in the draft EIS.

(63) The probability of seismic activity is not necessarily low in this area.

(64) "Soil compaction from construction equipment would be moderate on the predominantly loamy and gravelly soils. Loss of productivity would be no greater than an estimated 5 percent and should return to normal in 2 years." "Blasting and excavating the pipeline trench through the shallow soils would increase the potential for profile mixing and dilution. Without careful topsoil segregation and replacement the natural soil fertility would be reduced by at least 10 percent and would be permanent." What is "moderate" soil compaction? What is the source of information for the figures "5 percent" and "10 percent" as quoted? What measures will be taken to prevent erosion due to paucity of vegetative cover during the estimated 2 years to "return to normal"? What measures will be taken to ensure careful topsoil segregation and replacement?

(65) p.8-78 Legal problems involved in taking water from creeks with full water rights assigned have not been discussed.

Two percent of streamflow means what? Over what time period?

"In the event of a pipeline rupture, oil would be carried to surface waters causing water quality degradation." Who or what agency would monitor pipeline impacts on aquatic resources? Preimpact studies? Construction impacts? Investigate the effects of spills?

(66) "The most important streams along this alternative route segment supporting fishery resources include the Clark Fork, and Little Blackfoot Rivers, and Siegel and Ninemile Creeks. Numerous tributaries to these streams are crossed."
Twenty-three streams are recognized for their sports fisheries value within the Ninemile-Mill Planning Unit (Fig. 6. Multiple Use Plan, Ninemile-Mill Planning Unit, U.S.F.S., 1976). The proposed pipeline will cross fifteen of these, not to mention severe

impacts on Ninemile Creek and Siegel Creek themselves. Further, the more precipitous streams tributary to Ninemile and Mill Creeks are believed to be home for the true westslope cutthroat trout (Multiple Use Plan, Ninemile-Mill Planning Unit, U.S.F.S., 1976).
What measures will be taken to protect these valuable resources?

(67) In general the impact on water resources has not been sufficiently studied especially in view of the fragility of the water resource structure.

(68) p.8-79 "Although the grassland range vegetation involves the greatest acreage disturbance the impacts should be relatively minor. Grassland could be restored and maintained at near present productivity shortly after construction."
Define "minor", "near present productivity", and "shortly".
How will restoration be accomplished?

(69) Re: big game winter range. "Construction during late summer would reduce impacts." And, "summer construction would reduce disturbance to waterfowl." In both cases, why?

(70) "Quantified wildlife studies are not available for most of the alternate route."
And this is an "impact" statement!?!

(71) p.8-80 According to the figures on p.8-77 the right of way in the Siegel Creek area would be 200 feet wide, not 90 feet wide.

CONT

(72) p.8-81 Transportation and Utility Networks. The passage of heavy equipment and workers would destroy Ninemile Road, presently a secondary county dirt road. No compensation would be made by NTPC; the county, through taxation, would have to pick up the cost.

(73) Recreation Resources. There are, in fact, a large number of hunters which use the Ninemile area. In addition the pressure of construction workers on campgrounds along Ninemile Creek would be very significant.

(74) Social and Economic Conditions. No mention is made of decreasing land values due to pipeline construction. Equally ignored is the long term damage resulting from establishment of this area as an energy corridor.

ADDITIONAL QUESTIONS TO BE ADDRESSED BY
THE FINAL E.I.S.

---

(75) a 1. Where will pump stations be located?

b 2. What excavations will be required for sand, gravel, or borrow material from streams or flood plains? Detrimental erosion or channel change at flooding due to this?

c 3. Will there be on site burial of refuse or petroleum based products?

d 4. Will spoil banks along the trench be lowered to approximate the original contour in order to preserve the natural ground water patterns and thus minimize postconstruction effects?

e 5. Have ditch blocks been considered as a means of deflecting water from the pipeline ditch thereby eliminating serious erosional problems? This is not mentioned in the DES.

GENERAL CONSIDERATIONS

Several weaknesses have become apparent as we analyzed the DES:

(76) 1. Two thirds of the proposed route falls on private lands. Yet this fact is ignored totally--as if people were not a major resource. Such impacts as property values are not addressed at all, and other significant impacts are dismissed as nuisances. In addition, the implications of eminent domain, especially as it would apply to access, has not been included. The opinions of local landowners, as well as the general public, has not been sought.

(77) 2. One major consequence of the pipeline is the establishment of an "energy corridor" which would complete the destruction started by the pipeline. Fragile areas such as Ninemile, Siegel and McDonald Passes, and the like would be destroyed. An independent study of the cumulative effects of energy corridors is necessary.

(78) 3. Water resources in general, and hydrostatic testing effects in particular, have been inadequately covered. Reams of statistics cannot cover basic ignorance. Vague promises by NTPC should not be confused with fact.

Just how far can water from the Ninemile Creek undergo planned usage as proposed by the DES? To begin with, the normal flow will be disrupted by the simple fact of trenching under 15 tributaries. Additionally NTPC proposes watering during construction to minimize soil loss. Next comes withdrawal for purposes of hydrostatic testing. And finally, watering after construction until vegetation is established. The applicant may find inspection of the U.S.G.S. Water Resources quite enlightening--BLM might too!

(79) 4. Discussion of the need for independent quality control and surveillance is necessary. The realities of pipeline construction can be easily ignored as witnessed by the Alaska pipeline experience.

(80) 5. Landowners in the vicinity of energy corridors will have to pay three times for corridor establishment: as a consumer of the products involved; in the form of losses, especially of property value; and again in the form of taxes to repair damages to public facilities. Momentary blandishments such as inadequate lump sum payments will not compensate the landowner.

(81) 6. The Ninemile-Mill Planning Unit has a history of extreme fire danger due to unnatural accumulation of fuels compounded by debris from logging, thinning and clearing. This threatens both the forest ecosystem and homes and property scattered throughout the planning unit (p.11, Multiple Use Plan, Ninemile-Mill Planning Unit. U.S.F.S. 1976). What measures would be taken to minimize fire danger during construction of the pipeline and, given the highly volatile nature of freshly leaked oil, to prevent conflagration during spillage?

(82) 7. How much irrigated agricultural land will be disturbed? A detailed assessment of impacts is certainly in order on this point. Will construction proceed during the irrigation season?

(83) 8. Finally, what must be considered more seriously are the alternatives to the Northern Tier Proposal. The BLM DES discusses three pipeline proposals which move Alaskan crude oil to the Midwest. These are the Foothills, Kitimat and Transmountain Reversal proposals. We question the small amount of time which has been spent to study these proposals, and we also question the validity of their "alternative" status when they are apparently inactive proposals at this time. (Again, this DES is antiquated and therefore incapable of accurate assessment of the project proposed.)

We feel the most viable proposal appears to be routing the pipeline along the same right of way as that proposed for the natural gas pipeline from Delta Junction, along the Alcan Highway, to Edmonton, Alberta.

(84) Three additional alternatives which have not even been considered and yet deserve serious attention are:

a) Reducing Alaskan oil flow to an amount that can be utilized on the West Coast.

b) Retrofitting West Coast refineries to handle the Alaskan crude oil thereby eliminating the need to import "sweet" oil from foreign sources to obtain the mix required by existing refineries. After all, energy independence is the national goal behind this DES--no?

c) And, if we're not after energy independence (i.e., if we're going to import foreign "sweet" oil), why not ship the Alaskan crude to Japan?

Obviously, the missing ingredient in this DES is time--time for proper preimpact studies, construction impact studies, and studies of postconstruction impact possibilities, as well as the time that is essential for accurate analysis of all existing alternatives to this proposal.

BLM-Northern Tier Project
Room 1250, Lloyd Building
700 N.E. Multnomah Street
Portland, Oregon 97232

Gentlemen:

Enclosed you will find additional comments and questions relating to the Draft Environmental Impact Statement issued by your agency for the proposed Northern Tier Pipeline project. These comments were prepared by Greg Prescott a consulting geologist who lives in the Nine-Mile area.

Once again we wish to express grave concern with the fact that this draft Environmental Impact Statement is both out-dated and inappropriate to the pipeline route as presently proposed by Northern Tier.

Thank you for the opportunity to express our concerns.

Sincerely,

Jan Raepe, Chairman
VALLEYS PRESERVATION COUNCIL

Nine Mile Rural Route
Huson, Montana 59846
March 29, 1979

*Critique of Geologic Sections*
*of B.L.M.'s Draft Environmental Statement*
*on N.T.C. Proposed Crude Oil Pipeline*

*Prepared by Greg W. Prescott*
*Consulting Geologist*

*GENERAL STATEMENT:*

*The writer is a professional geologist (Idaho Registration Certificate No. 411) with 12 years working experience in the Pacific Northwest involved with mineral exploration. After careful study of the subject Environmental Statement, I find in my professional opinion a number of obvious omissions, inaccuracies and misleading analyses of the geologic factors and associated impacts related to the proposed pipeline construction by N.T.C. No attempt was made to analyse the on-shore facility proposals and what follows is limited to the design features of the pipeline and the potential geologic hazards encountered along the two-mile wide study corridor.*

*SPECIFICS:*

① *The statement on p. 2-52 and p. 2-53 of the E.S. that only 13 surface faults are identified along the entire 1500+ mile corridor of which only three are recognized as active, is dangerously inaccurate in terms of a data base to design safety features and align the pipeline route. The detailed geologic data currently available for study along the corridor is voluminous and it is obvious that the geologic contractor, Furgo, Inc., for the B.L.M. statement has either ignored and/or dismissed as irrelevant this information base, since many times this amount of active and/or potentially active faults are recognized by federal, state and private geologic organizations.*

*A prime example of this type of omission is the 80+ mile pipeline segment from Thompson Falls, Montana to and beyond Missoula, Montana. No mention is made of any plans to deal with the existence of two major, potentially active faults which parallel and cross and recross the proposed pipeline alignment throughout this entire segment. These faults, the Hope Fault and Ninemile Fault (see U.S.G.S. Prof. Papers 346,719 and 866) as well as numerous subsidiary faults pose a real threat to the integrity of the pipeline over this 80+ mile segment. Granted no recent activity has been demonstrated along these faults in recorded times, but there is general agreement that they are definitely potentially active. Since the proposed route lies within the corridor of influence of these structures for over 80 miles of its length, it would seem prudent to allow for check valves, flex joints, special bed or other safety design features of the proposed construction to compensate not only for catastrophic ruptures, but potential passive creep along the faults.*

CONT

② *The Geologic hazards identified in Section II of the statement concentrates only on the catastrophic potential of the geologic environment. Consequently a serious omission of dynamic, yet passive, geologic forces has been made in the assessment of possible hazards and impacts along the route. Surface and/or soil creep is a geologic hazard not discussed in the proposal. Passive fault movement is a geologic hazard not mentioned by Furgo, Inc. in any of the sections of the statement. Dynamic subsidence and/or emergence on a regional scale in the various geologic provinces and the potential resultant stress gradients imposed on a possible pipeline, is also ignored in the geologic treatment of the proposed alignment.*

③ *The subject of swelling clays as a geologic hazard is dismissed on p. 2-52 as having a minimal impact and not a serious threat to the pipeline. Also it is evident in the statement that no specific plans, procedures, or guidelines are proposed or under consideration as to how unsuitable trench excavated fill is to be disposed of. I submit that this is a significant oversight by the pipeline planners. A substantial portion of the proposed route crosses areas which have high clay content in soils, glacial deposits and other alluvial materials in addition to the areas of Eastern Montana mentioned in the E.S. Should these materials after excavation be improperly handled, a very serious impact problem could arise in the form of stream silting. A specific example is the proposed route through the Nine Mile Valley where high clay content glacial till would be encountered. Neither the clay nor the boulders excavated in this section would be suitable fill material. Certainly this material once disturbed, could not be left exposed to surface runoff, yet no plans are mentioned in the draft E.S. to deal with the problem.*

④ *In the writer's opinion the subject of mineral resources is mistreated in the E.S. It was stated that no active mines exist within the two-mile wide study corridor. This fact says nothing as to the discovery potential or the near future viability of currently recognized mineral deposits along the corridor. As a specialist in mineral exploration I can attest to the fact that a very high probability exists that the currently proposed two-mile wide study corridor contains as yet undiscovered viable mineral deposits. Moreover I am confident that given careful study of the geologic data base, a satisfactory realignment of certain pipeline segments could be achieved which would minimise the interference created by mineral withdrawal along the corridor. That a study of this type was not made by the geologic contractor, Furgo, Inc., is quite evident and should be rectified before final alignment is made. A specific example of disregard for potential mineral resources is to be seen in the pipeline's alignment over the Kennedy Creek Basin in the Nine Mile Valley in Montana where substantial deposits of gold-bearing glacial till are present and estimated to contain roughly $50,000,000.00 in gold by the U.S.G.S. (see U.S.G.S. Bulletin 470).*

*CONCLUDING STATEMENT:*

*As a geologist it is obvious to me that the current treatment of the geological inputs to the N.T.C. pipeline proposal is grossly simplified and inadequate to yield the detailed information necessary for engineering, alignment and safe construction. Yet I see no overriding geologic factors which would dictate rejection of building a pipeline roughly along the proposed route. I suggest strongly that the inadequacies as above described be rectified by more careful and detailed study before a final pipeline design and alignment is approved.*

*Respectfully Submitted,*

*Greg W. Prescott*

121 CONT

ADDITIONAL COMMENTS AND QUESTIONS RELATIVE

TO BLM DRAFT ENVIRONMENTAL STATEMENT

Prepared by Greg W. Prescott
Consulting Geologist

5 Proposed route disregards topographic grain. In a vertical dimension the current proposed pipeline route exhibits a highly erratic alignment due to the crossing of a multitude of minor and major topographic features. At each reversal of grade, hilltops and valley bottoms, the potential for line failure is increased due to the resultant stress points thus created. Among the undesirable features of a highly fluctuating pipeline grade are:

1. Difficulty of construction leading to increased chance of mistakes.
2. Local high and low pressure points in the line which may exceed design margins during surges, or result in fatigue failures from constant wear, limit operation over the lifetime of the line.
3. The necessity to anchor the line to prevent accumulative lateral stress.
4. Stabilization difficulties during and after construction of soils.

6 The proposed route avoids agricultural land in favor of overland alignment. The current proposed route avoids agricultural lands where possible and favors heretofore undisturbed land. This approach to pipeline routing is highly undesirable from a restoration standpoint and in terms of total disturbance of the environment. By constructing the line across agricultural land where possible, nearly 100% restoration could be practicable achieved, stabilization and minimal visual impact practices are the only feasible restoration options now contemplated within the forest lands route.

Preferred routing guideline recommendations. It is my opinion that the safest, least expensive, minimal impact pipeline route would be achieved by incorporating the following pipeline routing guidelines:

1. Routing the pipeline along existing right-of-ways such as railroads, freeways, state and county highways and roads, existing pipelines and in some cases existing powerlines.
2. Routing the pipeline through agricultural lands where possible instead of forest lands.
3. Where overland or cross-country routing is necessary, contouring alignment or other forms of grade fluctuation minimization should be employed. Note: Clearcutting in this case along the right-of-way should be suspended in favor of permanent access roads along the alignment to facilitate on-the-ground inspection of the line instead of a fly-by inspection as is now proposed.

CERTIFIED MAIL

Dear Mr. Storms:

Thank you for the opportunity to review and comment on the Draft Environmental Statement - Crude Oil Transportation System as proposed by the Northern Tier Pipeline Company.

The attached comments address the draft Environmental Statement and the potential impacts of the proposed pipeline on Mason County. The comments submitted cover five general categories, which are: physical or biological impacts from construction, operational physical or biological impacts, pump station construction and operation impacts, socio-economic or transportation impacts of construction crews and equipment during the construction period, and finally, socio-economic implications of operation line failures.

We offer these comments to you on behalf of the citizens of Mason County. If you should have questions, please don't hesitate to call.

Sincerely,

James E Connolly

CONT

The potential impacts of the proposed Northern Tier Pipeline through Mason County fall into 5 main categories:

- Physical or biological impacts from construction
- Operational physical or biological impacts (oil leakage or spills)
- Pump station construction and operation impacts
- Socio-economic or transportation impacts of construction crews and equipment during the construction period
- Socio-economic implications of operation line-failures or related operation damages

Other impacts do exist and will be described below. However, these 5 areas are of prime concern to the county. The Bureau of Land Management (BLM) Draft Environmental Impact Statement (EIS) published in February 1979 does not address any one of these five potential impact categories in sufficient detail to be meaningful at the county level. While it may be argued that the EIS is national in scope and should not contain excessive detail, the purpose of the EIS is to provide necessary data for decision making based on all geographical areas of impact. The potential impacts on Mason County are substantial as enumerated below.

I. Description of the Proposed Action

1 (Pages 1 - 19)
While the only major highway to be crossed in Mason County is State Highway 108, many of the small roads leading west from Hood Canal are single entry roads which are the sole connection of goods and services for local residents. Blockage of these roads during construction would cause serious problems. In some cases, due to topography, it would be extremely difficult to reroute the road while construction took place.

2 (Pages 1 - 24)
The document identifies 2 major rivers in Mason County, the Skokomish and Hamma Hamma. However, Mason County studies have identified 14 more rivers and streams that may be significantly impacted by the proposed action.

Protecting the freshwater and marine resources of the county is a major concern. Aquaculture habitat, spawning grounds, and shellfish resources will be impacted in all the streams and rivers listed below:

Lilliwaup Creek (estuarine wetlands, anadromous fisheries, wildlife, fisheries)

Jorsted Creek (estuarine wetlands, anadromous fisheries, bald eagle habitat, etc.)

Eagle Creek (shellfish)

Finch Creek (fisheries)

Goldsborough Creek (City of Shelton water supply)

Cosnell Creek and Isabella Lake (fisheries, wildlife, wetlands, recreation and esthetics)

Skookum Creek (tidal wetlands, shellfish, waterfowl, wildlife)

Kennedy Creek (tidal wetlands, shellfish, waterfowl, wildlife)

Enetai Creek (fisheries)

3 The document locates mainline values only on the pipeline where it crosses the Skokomish and Hamma Hamma Rivers. Block and check valves must be located on every stream and river crossing to help protect them from possible oil spill contamination and the resulting deterioration of fisheries resources.

4 (Pages 1 - 27)
The location of the pump station in Mason County is referred to as T-20-N, R-4-W, Section 36, which would place it west of Shelton. This does not agree with the location shown in the Map Addendum, which places it at the western end of Isabella Lake. It is not certain which location is in fact intended.

5 (Pages 1 - 31)
No mention is made of pumping station dimensions. It appears that these stations could occupy 5 or more acres of land, causing significant impacts when placed at the upstream end of an important lake.

6 (Pages 1 - 41)
The location of construction staging areas in Mason County is not well defined. Any staging site would be a focus of widescale construction impacts including erosion.

7 (Pages 1 - 43)
The description cites a maximum of 480 construction personnel. However, this does not seem to include the 840 persons (mentioned later in the report) who would construct the pump station.

8 (Pages 1 - 46)
The document recognizes that construction times at major river crossings (the Hamma Hamma and Skokomish) should reflect a designation made by the appropriate state agency. The topographic, hydrologic, and biologic characteristics of the streams and rivers are not uniform. Therefore, scheduling of pipeline construction at all stream and river crossings must be based on the specific characteristics of that waterbody.

9 (Pages 1 - 47)
The document includes an incomplete section on clean up and restoration after construction of the pipeline. Soil suitability in Mason County is extremely limited for revegetation efforts due to soil types, steep slopes, and lack of sufficient soil. Therefore, restoration efforts must include revegetation monitoring to protect soils from surface water erosion and resulting siltation.

10 An inspection team, made up of representatives from appropriate state and local agencies and the Northern Tier environmental representative, should be empowered to monitor the revegetation efforts to insure compliance with environmental regulations.

11 (Pages 1 - 56)
The document summarizes the contingency plan to be prepared for the pipeline system prior to operation. Personnel and spill containment and cleanup equipment located at each of the district offices, (Spokane is the district office in Washington State), would normally reach the site of any leak in 1 - 6 hours, depending on the location of the leak and weather conditions.

The contingency plan as proposed is inadequate. Obvious environmental disaster would result if an oil leak were to occur anywhere along the pipeline corridor. More details must be presented on what equipment, personnel and financial assistance is to be given to Mason County.

12 (Pages 1 - 56)
The document summarizes additional measures proposed for environmental protection. Three concerns that are not addressed are listed below.

1) Routing the pipeline away from aquifers supplying the City of Shelton watershed area or that feed directly or indirectly into Oakland Bay/Hammersley Inlet.

CONT 12

2) Routing the pipeline away from Totten and Skookum Inlets to protect Olympia and Pacific oysters and Pacific hardshell clams habitat. Based upon five year averages of total production in Puget Sound, Mason County aquiculture accounts for 93.5% of all Olympia oysters, 60.1% of all Pacific oysters and 97.1% of all Pacific hardshell clams.

3) Routing the pipeline away from the sensitive geologic/soils areas located near the Hamma Hamma River and John Creek.

13 (Pages 1 - 58)
#25 of measures proposed for environmental protection is not effective. Financial aid has not been received by county and city agencies carrying out Pipeline Impact Studies. The Northern Tier Company has not helped with the identification of fund sources for the impact analysis study.

II. Description of the Environment.

14 (Pages 2 - 52)
The document does not contain sufficient baseline data on geologic hazards in general and on seismicity specifically. Only two faults are identified in Washington State, one of them located in Mason County. The Puget Sound Basin is the area of most higher intensity earthquakes in Washington State. (Bulletin of the Seismic Society of America; January 1953) U.S.G.S. open report 78-426 shows various inferred structures (faults, principle folds and large scale quaternary deformation) either parallel to the pipeline or possibly intersecting the route. High intensity earthquake activity in the Puget Sound Basin is very probable in the near future. (University of Washington Master Thesis - 1974)

A complete baseline study to inventory seismic activity has not been carried out by Northern Tier Company. Completion of an adequate geotechnical survey is required prior to any routing decision in Mason County.

15 (Pages 2 - 61)
The Hamma Hamma River crossing is in an area near or in tidal and freshwater wetlands. Tidally influenced sitka spruce-dominated swamps exist in this area and may exist at the proposed crossing location (see NEC 1979). The crossing at the Skokomish River occurs in an alder-willow swamp wetland. The existence of these wetlands at or near proposed crossing locations should be mentioned.

16 (Pages 2 - 80)
Jorsted and Eagle Creeks also have relatively high levels of salmon and general fish use at their lower end (see NEC 1979).

17 (Pages 2 - 96)
Bald eagle sitings are mentioned at the Hamma Hamma River and Lilliwaup Bay. However, these birds probably also use several of the more minor creeks in northern Mason County for either hunting or nesting.

18 (Pages 2 - 150)
The draft EIS fails to recognize the Skokomish and Squaxin Island Indian Reservations.

19 (Pages 2 - 152)
The document assumes that most construction workers will not be accompanied by their children during the school year. Northern Tier Pipeline Company should provide Mason County with pre-construction baseline school attendance/capacity data. This data will be used to measure future impacts of project related student immigration if this assumption proves to be invalid. Pre-impact payments or reimbursement plans for school impacts must be identified by the Northern Tier Pipeline Company.

20 (Pages 2 - 159)
The document states that Washington's rivers will become "intensely directed and controlled" by the year 2000. It should be pointed out that this is unlikely on the Olympic Peninsula portion of the route where water usage will likely remain directed toward recreation and natural area use.

21 (Pages 2 - 164)
The draft EIS makes no mention of population impacts from the Satsop Nuclear Power Project located in Grays Harbor County, Washington. Construction workers reside in Mason County and commute to that site.

III. Impacts of the Proposal.

22 (Pages 3 - 13)
The document states that hydrologic characteristics of streams crossed by the pipeline may return to preconstruction conditions in most cases. Considering the steep bank and unstable soil conditions present in Mason County, this statement is highly suspect.

23 (Pages 3 - 59)
Excavation impacts on many of the sensitive streams in the Mason County portion of the corridor could be major impacts for fish and wildlife resources rather than minor, short-term impacts as stated in the document. Construction in many of the V-canyons could completely block and disrupt these streams. (See NEC 1979 for detailed discussion of these effects.)

24 (Pages 3 - 61)
Although the document identifies the active Saddle Mountain fault in Mason County, it fails to recognize potentially active faults or sensitive geologic areas in the county. Since the Puget Sound Basin has been identified as a major geologic risk zone the Northern Tier Pipeline Company must comment on the geologic hazards anticipated with the presence of these inferred structures shown on tectonic map of the Puget Sound area. The draft EIS states that the potential for ground surface rupture as well as an oil spill resulting from a pipe rupture would be high and could damage approximately .75 miles of pipeline. Northern Tier must revise this estimate to reflect increased seismic potential in Mason County.

25 (Pages 3 - 62)
Agriculture accounts for 10% of the existing land use along the 2 mile-wide pipeline corridor in Mason County. Approximately 6,067 acres of farmland are located within the pipeline corridor. Approximately 3,801 acres of potentially productive agricultural soil (capability class 2 and 3) are located from the proposed pipeline route toward the shorelines of Hood Canal and Puget Sound.

The effects of a cronic oil leak on soil productivity would be severe. Detection of a leak too small to be located by remote sensing equipment would be overlooked until it was seen and stopped. As much as 3,540 barrels/day, assuming a through put of 709,000 barrels/day, could be spilled without detection. Northern Tier Pipeline Company must install leak detection devices at points along the pipeline to reduce spillage volume near agricultural lands. Northern Tier must also agree to reimburse property owners along the pipeline route for proven pipeline related damage.

26 (Pages 3 - 67)
Impacts on water quality are not likely to be short-term, lasting less than one month, as stated in the document. Sediments will in many cases cover spawning beds and work into the gravels, filling crevices used by anadromous fish for egg deposition.

27 (Pages 3 - 72)
The impacts on fisheries in Mason County could well be major rather than a minor impact as described in the document.

28 (Pages 3 - 75)
The document implies that sediment will remain trapped in spawning gravels for less than one year and that this will affect only one year class of fisheries resources. The first portion of the statement may not be true and has not, to our knowledge, been tested under similar hydrologic conditions.

CONT 28

Secondly, destroying one year class of salmon may cause severe damage to the total population utilizing many of the smaller creeks, since salmon generally migrate to the same stream.

29 (Pages 3 - 78)
In addition to the list of ways in which the document states fish may be affected by an oil spill, there will probably be indirect effects resulting from the destruction of wetland habitat at the stream mouths (which is of critical importance to the juvenile rearing stages of anadromous fish).

30 (Pages 3 - 101)
The document does not recognize the impact a pipeline accident would have on watershed/aquifer regions. Mason County is dependent upon watershed systems located within the pipeline corridor for its water supply. There is neither a sufficient baseline inventory of such aquifer recharge regions nor analysis of effects of an oil pipeline crossing over municipal water supplies. Contamination of water supplies is unacceptable to Mason County.

31 (Pages 3 - 102)
During the 1940's, I.T.T. Rayonier disposed chemical wastes in and around Goose Lake in Mason County. The practice of dumping toxic wastes has since been discontinued, yet the effects of this action may have some unidentified adverse impact on the oil pipeline. Northern Tier should investigate the potential degradation of the pipeline before final routing decisions are made.

32 (Pages 3 - 108)
The statements in the document regarding recreation and pleasure boating are not necessarily true for Mason County. Construction effects or oil spill on Hood Canal could have a significant effect on fisheries, shell-fish harvesting or pleasure boating.

33 (Pages 3 - 108)
Construction impacts along U. S. Highway 101 would be highly significant, particularly with the increased traffic volumes which will occur in the next several years due to the collapse of the Hood Canal Bridge. There is no alternative route in this area. Also, construction along Hood Canal will be difficult due to steep slopes and unstable conditions. Construction in Mason County will undoubtedly take longer than the one month period quoted in the document. Northern Tier must reimburse the county for any repair, enlargement, or modification of existing roads and meet local requirements when building new roads.

34 (Pages 3 - 109)
There is no mention in the draft EIS of the impact the project will have on the Shelton Airport. Officials plan to expand the facility and the only area for growth is into the pipeline corridor.

35 (Pages 3 - 109)
Construction or roads to carry construction equipment could be a major impact in the steep, unstable mountain slopes along Hood Canal. Detail on this is completely lacking in the EIS.

36 (Pages 3 - 112)
Recreational activity along Hood Canal is an important part of Mason County's economic base. This activity will be highly affected during construction by road blockage and the expected influx of workers and their families.

37 (Pages 3 - 113)
Impacts on Isabella Lake due to pipeline and pump station construction could be direct impacts of a major significance.

38 (Pages 3 - 119)
Apparently, calculations of workforce expected in Mason County are based on pro-rating construction workers per lineal mile of pipeline. Since the terrain is very difficult in the Mason County section as compared with other counties in this spread (particularly Clallam and Thurston), numbers of workers and length of construction time shown in the tables is probably low. Actual numbers and associated impacts can be expected to be considerably higher than shown.

39 (Pages 3 - 122)
It is not clear whether the pump station work force (which is considerable) appears in Table 3.2.15-3. If not, this would substantially increase population.

40 (Pages 3 - 124)
The document does not recognize a method for renumeration for impacted road services, police and health services, emergency tactical teams, and rural fire district teams in Mason County.

41 (Pages 3 - 125)
Economic and operational strains would be intense, particularly for small businesses along Hood Canal which are not set up to handle large numbers of transient workers.

IV. Mitigating Measures Not Included In The Proposed Action.

42 (Pages 4-1 - 4-10)
The document does not recognize alternative design of the pipeline where deep canyons exist and unstable soils result. V-shaped canyons pose particular construction problems in that no floodplain alongside the stream is available for staging construction equipment, or stock piling excavated material. The most significant construction impacts will be caused from erosion and excavation. These impacts can be reduced in steep sided V-canyons with trestles over riverbeds and trestles over narrow canyons. At least 4 streams in Mason County would benefit from the use of trestles; Whiskichek, Sund, Miller, and Finch. In trestle areas, a collection through below the transmission could be used to divert any oil leakage back to holding ponds outside of the river floodplain.

The document does not recognize that the pipeline must be designed to withstand an earthquake of such duration and intensity as is likely to occur in the Puget Sound Region. The EIS should discuss mitigative measures for the streams along Hood Canal, including the installation of block and check valves at creek crossings for Jorsted, Eagle, Lilliwaup, Finch, Goldsborough, Cosnell, Skookum and Kennedy Creeks. All of these streams contain important county resources. The mitigative measures which are discussed need to be less vague, particularly construction timing in relation to salmon. Crossings should also avoid wetland areas and spawning beds.

The document does not recognize the advisability of locating the pipeline crossing of the Hamma Hamma River and John Creek upstream of the sensitive geologic/soils area. Potential faults are located all along the pipeline corridor and this inferred fault is of particular concern to Mason County.

The document does not recognize the need for baseline data on the location of ground water aquifers which supply municipal water needs. The applicant could prevent water contamination from oil spillage by locating the pipeline away from these environmentally sensitive areas.

123 CONT.

㊷ The document does not recognize the need for revegetation monitoring enforce restoration efforts following pipeline construction. Especially in sensitive soils and slope areas, the revegetation followup would help mitigate impacts of erosion and resulting siltation.

The document does not address the issue of financial remuneration, liability and responsibility for action and mitigation.

The draft EIS does not recognize that a firm construction schedule is needed to alleviate impact identification problems and allow for proper lead-time for the planning of mitigations.

Map Addendum

㊸ The map addendum does not identify aquifer and watershed regions, or sensitive soil/geologic areas. The Skokomish and Squaxin Island Indian Reservations are not shown on the maps.

(Page 20)

㊹ The descriptions of critical resources impacts at the Hamma Hamma River and Annas Bay are generally complete. However, abundant harbor seal haul-out areas are also present at Annas Bay (Skokomish River). Additionally, salmon resources are significant enough in these areas to be emphasized over general fisheries resources.

(Page 20)

㊺ Since many of these resources listed for the Hamma Hamma and Annas Bay are present in some of the major creeks (See Evaluation of Norther Tier Oil Pipeline Through Mason County, Washington, Northwest Environmental Consultants, 1979) such creeks should be listed here as "critical" or at least "significant."

(Page 77)

㊻ The map near Pump Station #2 shows the area as critical for waterfowl. In fact the northern end of Isabella Lake is highly critical for fish, wildlife and is a high quality aquatic ecosystem.

---

124

UNITED STATES DEPARTMENT OF AGRICULTURE
SOIL CONSERVATION SERVICE
West Technical Service Center, 511 NW Broadway, Rm. 510, Portland, OR 97209

March 30, 1979

Mr. A. K. Leonard, Project Manager
Northern Tier E.S. Team
Bureau of Land Management
Room 1250, Lloyd Building
700 NE Multnomah Street
Portland, OR 97232

Dear Mr. Leonard:

The Soil Conservation Service has reviewed the Draft Environmental Statement, Crude Oil Transport Systems and has the following general and specific comments.

General Comments

1. The draft appears very comprehensive. However, the document would be considerably strengthened if the effects of the project on land use and cover along the pipeline were more comprehensively evaluated and displayed.

① For example, throughout the report the loss of production from the affected lands has been mentioned, but not quantified; e.g., page 5-13 (5.2.5 soils). "Soils in the right-of-way would produce nothing during construction" and page 5-20 (5.2.12 land use). "Across agricultural ② lands, construction activity would preclude production for at least one season on approximately 6830 acres of cropland and improved pastureland. The subsequent years productivity might be reduced by 5-10 percent assuming proper double trenching effectively segregates and replaces top soil." We strongly suggest the impacts of this loss of production be quantified in economic terms.

③ 2. The statement does not clearly discuss to what extent conservation systems will be altered, severed, or suffer blocked outlets.

④ 3. The statement does not clearly indicate that enduring soil and water practices are to be installed and maintained. Segregation of top soil during construction is discussed but no mention is made of stockpiling top soil for future use.

⑤ 4. There is a need to address possible erosion or erosion effects that may occur on adjacent lands when the damage(s) may be induced by pipeline construction.

⑥ 5. It appears that the environmental impact statement has identified the potential geologic, soils, erosion, and other related problems that may occur, but it should also address all the remedial measures, if any, to counteract these potential hazards. For instance, revegetation of the soil disturbance along the pipeline route may not always suffice on steeper slopes. What other alternative soil erosion measures would then be used?

⑦ 6. Do the efforts for controlling soil erosion, etc., apply only to the original entry, or to subsequent entries under the easement authority?

CONT.

⑧ 7. Many erosion control practices that may be needed, such as diversions, water bars, and erosion control structures, are not identified or discussed in the environmental statement.

⑨ 8. For that reach of the pipeline for which prime and unique farmland data is available, the draft environmental impact statement should display any prime agricultural lands that may be affected by pipeline construction. Impacts on these prime agricultural lands should be discussed.

⑩ 9. There should be some provision made for follow-up after construction for 5 to 10 years to determine if grass seedings, structures, etc., are performing properly to control erosion and prevent pollution.

10. Sharptail grouse dancing grounds are addressed; however, no proposal for avoidance of these grounds is recognized although construction adjacent to these grounds would only be a temporary disturbance.

a 11. We recommend the route south of Coeur d'Alene Lake rather than the one crossing the Spokane-Rathdrum aquifer. We recommend also the route over Jackass Pass rather than the one at the North Fork of the Coeur d'Alene River, which would require 24 river crossings in 23 miles.

⑪ 12. The material sent in from the Coeur d'Alene and St. Maries SCS field offices in Idaho during earlier planning is still pertinent as to the designated route and does not appear to be reflected in the E.S. This data covered impacts on erosion, land use, cover, crop, pasture and forest production, conservation practices, stream crossing, and habitat effects. Other field offices that sent in similar information had the same comment.

⑫ 13. There is also a concern about scattering noxious and other type weed seeds. The pipeline route goes through heavy infestations of goatweed, leafy spurge, dalmation toadflax, whitetop, and spotted knapweed. Utility corridors are ideal routes for weed infestations because seed is brought in on the earthmoving equipment and other vehicles.

⑬ 14. The area in western Montana including the route from Thompson Pass through Prospect Creek Canyon and up the Clark Fork River from Thompson Falls to Plains (alignment sheet No. 9 in the map addendum) is a very fragile and hazardous area. It is felt that resource concerns in this area have not been adequately covered in the environmental statement.

⑭ 15. At some stream crossings it is indicated that no permit is required. Example, Thompson River near Thompson Falls, Montana, on alignment sheet 9, pages 90 and 91 in the map addendum (designated by No. 58). There may not be a requirement for a U.S. Corps of Engineers permit, but because of state law a permit may be needed for the Montana Streambank Preservation Act through local conservation districts.

16. Montana water use permits for using local water for testing, etc., may also be needed and may be difficult to obtain during certain times of the year.

17. There appears to be some concern that proper consideration be given for co-location with other proposed utility corridors, such as the proposed electric power transmission system (the Colstrip project).

⑮ 18. Because of recent change in the pipeline route in western Montana, the information (soils, crops, etc.) originally submitted to BLM is no longer valid. The new route will encounter more stream crossings, soils needing more erosion control practices, and more difficulties in establishing vegetation.

⑯ 19. The Operation and Maintenance portion does not include many of the conservation practices that are to be applied. For example, because of the difficulty of establishing vegetation on some of the soils and the possibility of failures, follow-up work will be needed as well as maintenance of these conservation practices.

Specific Comments

⑰ 1. Page 1-46 - This page partially addresses maintaining the integrity of wetlands. However, pages 5-18 and 8-83 indicate that wetland loss could or would occur. This appears to be contradictory and, if so, should be explained.

⑱ 2. Page 1-47, paragraph 5 - Should be changed to provide for appropriate state laws on surface mining reclamation rather than just guidelines.

⑲ 3. Page 2-10 and 2-11, Seismicity - The proposed tanker unloading facilities, the submarine pipeline, and the off-shore storage facilities would be critical structures in case of a potential damaging earthquake. In view of the location of these structures being in a seismically active zone (risk zone 3) and the close proximity to soils subject to liquification and land instability, it would seem necessary that a detailed geological and engineering soils study be completed. The results of the study would assist in installing the needed design features to be incorporated into the proposed structures.

⑳ 4. Page 2-12 - In the second paragraph under 2.1.15 Soils, several soil series are mentioned as major soils. Only one is identified in the legend. This seems inconsistent to discuss Bellingham, Dick and Rifle as major soils and to not show them as a component of a mapping unit.

㉑ 5. Page 2-12, sixth paragraph, 2.1.15 Soils - There is a very questionable statement made on the geology. This should be checked out.

㉒ 6. 2.1.2.5. Soils (page 2-54) - Some clarification is needed as to just how much of the pipeline route is on land where detailed soils information is available. For much of the pipeline route this detailed soils information is not available. Prime farmland, for example, cannot be identified without this detailed soils information.

㉓ 7. Page 2-55, Soil Series and Table of Soil Characteristics - The author has confused taxonomic units and mapping units.

㉔ 8. Page 2-56 - The environmental statement indicates that fewer problems will be incurred in the Northern Rocky Mountains than on the Great Plains. We expect that less good top soil for revegetation is available in the northern Rocky Mountains than on the Great Plains.

㉕ 9. Some errors were noted in the data presented in Table 2.1.2.6-3, page 2-59, and Table 2.1.2.6-7, page 2-66. The streamflow data for Washington and Idaho was checked using U.S. Geological Survey Water-Data Report. A thorough check of data presented in the report needs to be made.

㉖ 10. Page 2-91 - The Soil Conservation Service has forage production estimates available that should answer the statement. "Estimates of average production are not known at this time."

㉗ 11. Page 2-93 - Photos 4 and 6 do not match with the corresponding descriptions and should be reviewed for their accuracy.

㉘ 12. Page 2-77 - "P. Randick" should be spelled "Randich." Also, the Geology and Ground Water Bulletin number of Kidder County, North Dakota, is 36 not 39.

㉙ 13. Page 2-139, paragraph 13 - The Prairie Pothole Region supplies waterfowl for hunters in North Dakota as well as other areas of the United States. Document should be changed accordingly.

㉚ 14. Page 2-163 - Recreation Resources (Cle Elum, Washington, to Plummer, Idaho) - Reference to a planned casino development in the Cresent Bar, Washington, is inaccurate. As yet, casino gambling in Washington is still illegal, at least at the time of this document.

㉛ 15. Page 3-65 - We suggest that the Soil Conservation Service's method of construction-revegetation of channels for North Dakota be considered. Basically the concept is vegetate immediately following construction and only a certain length of exposed area can be constructed until revegetation must begin.

㉜ 16. Page 3-70, fourth paragraph - Reference is made to five-day biological oxygen demand (BOD). We recommend the authors check their references since BOD usually refers to Biochemical Oxygen Demand.

㉝ 17. Page 3-80 - It appears some estimate of productivity of forest land that would be lost should be made. This could be approximated from Table 3.2.8-2 by forest types, assigning productivity rating per type.

㉞ 18. Page 5 (Chapter 5) - Under adverse impacts, there appears to be no consideration of the trespass damages by contractors and others to the area outside the corridor or easement area. There no doubt will be some.

㉟ 19. Page G-5 - Shrink-Swell Potential section on low and high has the language, "Following are examples of soil series. . . ." This sentence should be deleted as there are no "following examples" given.

We appreciate the opportunity to review the draft E.S. and will be happy to provide additional consultation on our comments if requested.

Sincerely,

Kenneth L Williams
Director

March 26, 1979

125

① Bureau of Land Management
Northern Tier Project, Room 1250
Lloyd Building, 700 NE Multnomah
Portland, Ore. 97232

This addendum is to raise some additional questions and state some concerns not expressed on March 15th. Hopefully the briefness will not lose the meaning being conveyed.

On March 26th Northern Tier Pipeline Company went to the Washington State Energy Site Evaluation Council (EFSEC) with a proposed route change that would go from Port Williams in Clallam County to Partridge Point on Whidby Island, thence to Camano Island, through the Stanwood area and south. This alternative is described very briefly in the BLM draft, chapter 8. In fact, so briefly it neglects to mention the impacts on the fisheries of the area and has no oil spill trajectories for the Whidby-Camano Islands segment. This move is supposed to make it more palatable for the inbound refineries to hookup to the NTPC, yet there is no comprehensive analysis of the 3 berth, 1.2 million bpd throughput and the attendant storage needed. However on page 6-6 out of the blue "onshore storage facility with the full complement of 35 tanks", is this an error and on whose part or is there more to the project than is being presented?

Also on March 26th, Bill Sage, a NTPC coordinator announced on the local radio station KONP a new alternate berthing area to be east of the present proposal and would encompass the present Coast Guard Base. If NTPC's continual changes weren't so serious it would be comical, its certainly ridiculous. What are the impacts to the Port Angeles community if the coast guard base is no longer on Ediz Hook, both from an economic and a safety standpoint? Will the Coast Guard leave the area for Oak Harbor and Westport? The BLM draft states the NTPC will mean the need for 2 more coast guard personnel at the hook. And what of the present naval and FAA equipment operations at the CG base? What will happen to the historic site at the end of the hook?

Port Angeles Harbor presently has a class A water quality rating. How is it possible to allow a project that would by your own draft statement change that rating to a class C?

Barge traffic and spills for a 3 berth project are not adequately addressed. What about decreased air quality due to barge and tug traffic?

The Strait of Juan de Fuca will be the entry link between the Pacific Ocean and the Trident Submarine Base at Bangor, Wa. What effect will the increased tanker traffic have on this activity?

In page 1-1, 1.1 Purpose, paragraph 1 lists the Northern Tier states as defined by the Alaska Natural Gas Transportation Act of 1976, this does not accurately reflect figure 1.1 on page 1-2. Table 1.2-3 on page 1-5 does not speak to the Montana oil potential or recent finds in the western U.S. and N. Dakota.

[illegible] electric [illegible] projections seem to be based on 375,000 bpd throughput. Projects should reflect the total project needs.
Page 1-11 submarine lines [illegible] periods would seem to dispute the need for a third submarine line even with a 1.2 million bpd throughput.

page 1-15 Fire protection
How many men will be on duty and trained for firefighting in case of fire at the tank farm? Does the Public Utility Water System have the available water sources to provide water for fire fighting? It's my understanding they do not from comments made at the January 15, 1979 PCD meeting. The Port Angeles fire dept. is not the fire protector of the Green Point area. Green Point is served by local fire district #3 with volunteerfiremen. Backup comes from another local fire district #2 also manned by volunteer firemen.

Page 45, map add. designates the hook as a stable slope. There is little mention of the Ediz Hook erosion problem and the costs to maintain it from breaching. News article enclosed. You will note that it will require continued maintenance on a regular schedule.

CONT.

map add. 126-131
No mention is made of special treating of the pipe in areas where soil conditions are highly corrosive to steel.

page 1-30 Communication linkup combines land lines and microwave. The design for this system is based on leased service. Is this standard operations procedure? Who bears the liability and responsibility in case of problems? What are the impacts of the microwave system? They have not been addressed at all.

page 1-58 para 3 Contingency plans
The port authority for Port Angeles harbor is the Coast Guard, the local Port of Port Angeles has no authority other than its own facilities.

page 1-58 #25 Pray tell just what effect grants and loans for energy impacted areas would accomplish if there is no energy available? Suggest NTPC supply the needed energy through negotiated agreements from other areas, such as their wheeling concept. Then local area and state would be more able to supply existing business and industry when the 1983 power crunch comes.

page 1-58 #27 How will NTPC abide by this agreement for ballast if a VLCC requires up to 33% before leaving the harbor? Purging cargo tanks 10-20 miles from the harbor is still within the Strait of Juan de Fuca and residential areas, numerous tourist sites and Vancouver Island. How will the Port of Port Angeles, the operator of the dock facility or NTPC enforce such a requirement? The Coast Guard is the only authority with that power.

#28 The downtown Port Angeles area has had an air particulate pollution problem. Local industry and the city have been paving and using other means to overcome this problem, all without the help or assistance of NTPC. News article enclosed. Northern Tier has promised much but the hard fact of reality is they have provided little except fast talk and changing proposals.

page 2-8 Why weren't more noise readings done over a longer period of time to get a truer measure of the noise levels? More locations would also have been more graphic and have greater potential for substantiation.

page 2-15 wind generated waves Harbor is protected from such "except from the northeast" Isn't the direction the northeast?

page 2-28 other uses That is the skimpiest description of the Coast Guard facility and related uses on the base. Isn't there some naval instrument equipment operating on the base?

page 2-33 Why not use the Puget Sound Pilots station or VTS Coast Guard figures for vessel traffic rather than ASCO? Why isn't there a table showing the commercial fishing and recreational boat ownership for the Olympic Peninsula?

page 2-94 para 3 "The number of miles to be traversed by the proposed pipeline through wetland types is not known at this time." Is this a definitive statement? Certainly not informative.
78
page 2-column 2 What impacts will the NTPC have on this area that is of prime importance to the nation as a whole?

2-119 & 120 "Almost all of the forest land crossed by the corridor in the Puget Sound region is considered commercially productive". What is the NTPC impact on this region? What is the economic value and will it be reduced because of the NTPC?

table 2.1.2.15-3 Why aren't there any county or local police listed for Montana? Are the state police responsible for all the law enforcement in the state?

page 2-155, 2.2.1.13 Transportation and utility networks
Speaks of inland water transport opportunities without the NTPC project. Page 6-1 tanker unloading berths, speaks to commitment of the harbor to NTPC deterring additional development over the lifetime of the project. What is the negative and positive economic value impact on the port and community of such restrictions?

section 2.2 does not even acknowledge the Coast Guard base and its continuing and possibly expanded functions.

pages 3-44 & 45 I question your estimated peak traffic counts of project related traffic. If the project is on Ediz Hook what happens to the 800 of the project related 1020 in the downtown area? Your assessment of traffic impacts on county, city and state roads is clearly understated.

pages 3-6 & 7 How will the Coast Guard effectively enforce rules and regulations if it is no longer in the area?

page 5-3 para 3 If "the project cannot be determined with an acceptable degree of reliability" because of geologic event ... how is it possible to determine what 9 months of pile driving will do to a "high quality gravel" pile (meaning Ediz Hook)? resource for above page CL 118 Coastal Zone Atlas, Wn. Dept. of Ecology

page 2-32 para 2, also table 2.1.1.13-3 page 2-33 and map add. III-5
"Piers" might better be described as berths. There certainly are not 30 projections into the harbor for docking, but rather far fewer projections able to moor vessels of varying kinds. Also map addendum does not designate all "pier" areas in area, i.e. Port of Port Angeles Docks, M & R dock nor Port Angeles boat haven.

page 2-37 The numbers of ferry passengers carried to and from Victoria, B.C. by the ferry Coho should be listed. Especially peaks and lows, not just averages.

page 2-42 table 2.1.1.15-8 Why were intraharbor movements excluded from table? Why were 1977 figures not used? Were commercial fishing vessels entering the harbor included in the table? If not, why? Why was data adjusted relative to foreign oil imports?

page 2-137 The mill terminal for the Port Angeles harbor is long gone! However, there are four harbor proposals presently on the drawing boards and in final stages preparatory to building, which will definitely increase the economic base of the area. News articles enclosed.

page 6-1 A 20 plus year commitment of the harbor to the NTPC project with both immediate and long term restrictions on industrial and recreational uses would be an economic strangulation on the community. Have these losses been calculated? What are they?

page 6-2 tanker berths para 2 Last sentence leads one to believe the project would be a short term sacrifice of less than normal concern and little impact. What is the basis for such a statement? A life based on local natural resources involving production of products from federal and private timber sources; a tourist industry relative to the harbor, Olympic National Park and Victoria, B.C.; a shipping industry that provides an [illegible] help to a balance of trade debit rather than deficit; a commercial fishing industry base; what are the economic values of these?

page 5-7, 5.1.13 para 1 & 2 Where will tanker queuing take place, in the harbor or elsewhere? How large is the nonanchorage area to be over the submarine lines (3)? Why has it not been designated or shown in graphic form? Exactly what impact will increased tanker traffic and queueing have on restricting present incoming and outgoing vessel traffic-i.e. logbooms, barges, logships, ferry Coho, commercial fishing boats and recreation boats (both motor and sail)? What will the impact be on the inner harbor movement of lografts and chip barges from one place to another? What impact would a restricted anchorage designation have on present vessel anchorage? How would a VLCC 325,000 DWT tanker at anchor in the harbor affect or restrict existing harbor traffic usage and vessel movement? How many tankers of what size could be anchored in the harbor and still have the present normal vessel movement? Where outside of the harbor would waiting tankers anchor? What specifically would be the "occasional inconvenience to other commercial vessel traffic"? Is this local commercial traffic or is it commercial traffic going inbound or out to sea? Or both?

page 5-12 Isn't it interesting that we will lose property tax revenues on abandonments, yet therein nowhere in this document sufficient factual material to determine with any accuracy whether there will be enough incoming revenue to offset the costs of [illegible] local government units will be responsible for providing?

125
CONT

Air quality impacts have not been stated as they are understandable by the layman concerned about his tree farm, orchard or garden and the impacts thereto.

At the NTPC briefing held in Sequim on November 21, 1978, John Laque of EPT when questioned stated Sequim had had a high ozone reading at the Sequim Fire Hall in 1973. What caused this high reading and what effect will the NTPC project have on such existing factors?

page
2-38 What will be the impact on the Puget Sound area of sulphur dioxide and ozone pollutants coming from the Port Angeles area?
2-152 2.2.1.2 air quality para 3 Little change in sulphur and oxides is anticipated without NTPC. How would the NTPC affect this statement? Especially when ours 3 ranks to limiting of any future industrial growth because of the class I designation of Olympic National Park?
page
2-158 What will be the impact on existing industries ability to expand relative to air quality standards if NTPC is in the harbor? What is the air quality impact with a 3 berth facility handling up to three 327,000 DWT tankers concurrently in the harbor?

3.1.2 Since NEPA and SEPA require impacts of a total project to be addressed, what are the maximum increases of daily and average annual sulphur dioxide concentrations, nitrogen oxides and ozone levels with a 3 berth, 25 tank storage capacity project?

page 3-3 Why the use of old data from Coast Guard base that is not relevant to higher elevation areas back from the shoreline with different terrain, temperature and wind patterns? What will the effect be of the added sulphur dioxide and hydrocarbons on the area between the proposed port and the tank farm? What are the sulphur and ozone impacts on the Morse Creek and Elwha River draws (valleys and canyons)? Why wasn't northeasterly wind pattern air monitoring or modeling done for the harbor and tank farm? In the past few years wind patterns in our area have been changing.

page 5-2 Why have no significant mitigating measures been identified for air quality?

page 5-9 What is the specific "potential regional power supply shortage" with the NTPC in Washington State? What is the actual and real impact on existing industry power requirements? If a shortage does occur, will the local industries be required to shut down while NTPC continues to operate? What impact would that situation have on the local economy? Would new industries be restricted from locating in the area or state because of the power shortages? What would the NTPC project impact power demands be on the region's ability to attract new industry to Washington and surrounding states?

map add. page 19 NTPC has been rather blase' about the electrical power questions, talking about wheeling of power which does not seem feasible easily accomplished from this map. They have also said they could go to diesel pumps. Has an air quality assessment been done on such a possibility? How would that effect the cost vs benefit of the proposal?

The Missoulian Daily carried a small item on March 20, 1979 about the appointment of an energy manager for the BLM office in Billings, Mont. Copy enclosed. Strongly question such an action at this time. Private land owners could feel coerced.

The NTPC proposal has been totally negligent in adequately addressing the impacts and consequences of its project on our Canadian neighbors across the Strait of Juan de Fuca. Oil know no invisible boundary, national or otherwise.

Mr. Dan Betts of the U.S. Energy office at a symposium in Seattle on March 23, 1979 stated the BLM draft ES on Crude Oil Transportation System would be the only draft document issued on the several proposals so far submitted.

Changes by Northern Tier Pipeline Company of locations on March 26 and just before the deadline for submittal of comments relative to the project certainly give NTPC a decided advantage by not allowing sufficient time for those areas affected to peruse the large document and make their concerns known to BLM. This would appear to be a violation of the NEPA process. More time should be allowed for those affected to make comment, since this is their only opportunity.

Respectfully submitted,

Rosemary Cockrill

RE: CLALLAM COUNTY RESPONSE TO DRAFT E.I.S. -- NORTHERN TIER PIPELINE COMPANY'S CRUDE OIL TRANSSHIPMENT FACILITY

Dear Sir,

The Northern Tier project would be one of the largest oil port facilities ever proposed. The impacts and ramifications of such a project would be immense and far reaching. Considering the magnitude of the proposal, the D.E.I.S. that B.L.M. has published is totally inadequate. An in depth study of the document has revealed many erroneous assumptions, conclusions, and a general lack of credibility regarding the nature and scope of the impacts relating to social, economic and ecological consequences of the oil port proposal.

Furthermore, the County has recently been informed that Northern Tier plans to utilize an alternative route across Puget Sound, instead of the previously proposed route around the sound. Consequently, the B.L.M. Draft E.I.S. has become outdated because the alternative section dealing with the underwater Puget Sound route was grossly inadequate in analysis of the impacts. The County has now learned that B.L.M. does not plan to recirculate a new draft statement as a result of that change. The County must protest this decision as an obvious violation of the intent and purpose of N.E.P.A. Even before this change, the County had requested that B.L.M. redraft and recirculate the draft because of the gross inadequacy in impact analysis; see County Commissioner Ron Richards' speech, March 15, 1979, B.L.M. Hearing. With this new substantial change in pipeline route, the County must reiterate its concern that the draft be amended and recirculated. In support of this position, we would refer you to S.E.P.A. guidelines W.A.C. 197.10.495 where it states that a S.E.P.A. Draft E.I.S. shall be amended and recirculated when a substantial change has been made to the proposal. While B.L.M. is not operating under the dictates of S.E.P.A., surely the spirit and intent of N.E.P.A. would also require further analysis and recirculation under such special circumstances.

The B.L.M. product the County has reviewed represents a token effort to comply with federal regulations and any decision to not amend and recirculate the Draft E.I.S. must be considered an affront to the spirit and intent of the National Environmental Policy Act. The inattention B.L.M. has given to the impacts could ultimately result in the project having an adverse effect on the health and welfare of the American public. Clallam County hereby submits the attached materials and this cover letter as its official critical comments identifying the major deficiencies of the B.L.M. Draft Environmental Impact Statement regarding the Crude Oil Transportation System Proposal.

Port Angeles, Washington

April 2, 1979

Dear Board and Council:

The attached report is submitted for your consideration and the consideration of the U.S. Bureau of Land Management in its preparation of the Final Environmental Statement on the Northern Tier Pipeline Company project application. The material is a compilation of comments and data generated by Task Force members in the evaluation of the Federal Draft Statement. These comments reflect members' personal knowledge, technical expertise and individual research. Numerous references and authorities were utilized, including local, state and federal government agencies.

This report is a compendium of member input. Comments are included verbatim unless more than one comment on the same issue warranted a summary statement or unless it became necessary to render a comment more concise and/or more clear. Utmost care was given, however, to preserving the intent of the original comment. Editorial remarks were generally excluded in the attempt to maintain a factually-based review. Throughout the course of the evaluation process, it has been the principal goal of the Task Force to accomplish an objective and factual review.

Topic committee members were the primary contributors in each subject area. However, in many instances, members contributed comments on several subject areas. Additionally, several topical committees, by the very nature of their respective subject responsibilities, overlapped in scope of review. Examples of these were the Oil Spill, Fisheries and Harbor Management Committees; Law Enforcement, Fire Protection and Emergency Services Committees. Although attempts were made to minimize redundance, some overlap has inevitably occurred. Hopefully, whatever overlap is evidenced in this report will serve to underscore the multifarious impacts of this kind of project proposal.

As you know, the City-County Task Force is comprised of over 100 citizen-volunteers on 24 committees. The attached report is the product of a remarkable citizen effort to participate in a public review process. Task Force members had scarcely a month to review a copious, and rather tedious document, produced by a team of 45-professionals plus a number of professional service contractors over a period of 11-months and costing $3½ million. Local government should be indeed proud and extend profound appreciation to these citizens who have made such a significant and wholly voluntary contribution to this effort. Their participation has represented numerous long hours reviewing the document, pursuing source materials, confirming references, participating in regular committee meetings, drafting comments, etc. In summary, they gave their best effort and it is laudable.

The National Environmental Policy Act (NEPA) has been interpreted in Court as requiring a "full disclosure" Statement. A Federal Environmental Statement is not only expected but required to be a full and thorough assessment of impacts consequent to a project application. A Draft Environmental Statement (DES) is circulated for public review and comment in order that the public have every opportunity to assist and to assure that the process is serving the public interest.

CONT

When, in the course of review and comment, it is found that the DES is not a full and thorough disclosure then it may be assumed that the public interest is not being served. If member comments are a measure of corporate opinion, it was the prevailing opinion of Task Force members that this DES lacked sufficient data and detail. Specific references to these shortcomings are cited herein. Hopefully these comments will be of value in the preparation of the Final ES.

In addition to Task Force member comments, this report contains a critical evaluation of the Draft Environmental Statement prepared by Reed Hansen of The Urban Institute, Washington D.C. (See Appendix A) His comments are detailed and specific and reflect the expertise of the Urban Institute in performing social research and economic analysis. Mr. Hansen's evaluation is to be considered a substantive part of the Task Force comments and requires the same thorough reading and response that the BLM should give the body of this report.

It is my understanding that these comments and the appendix material will be transmitted to the Bureau of Land Management in the company of the statements of the City and County. If I can be of further assistance, please do not hesitate to contact me.

Sincerely,

Mike Doherty, Coordinator
Oil Port Task Force

## AIR QUALITY

① Summary: Page 21
Omission: Consider regular volumes of air pollution resulting from slash burning in forest areas of Clallam County.

② Ommission: Air quality impacts are regional in nature. The combination of present pollution levels (from local industry, vehicles, slash burning, etc.) and the contribution of a potential oilport (plus probable secondary petroleum - based industry - See the "Land Use" section of this report) will create a significant pollution problem. The California Air Resource Board projected severe impacts on the entire Los Angeles Air Basin from the Sohio project. It appears that the equivalent land area in Washington would extend from Cape Flattery to Bellingham, Bellevue and Tacoma. It should be noted that the Sohio project was approximately one-half the size of the Northern Tier project. The BLM should provide a thorough analysis of regional air quality impacts .

③ Summary: Page 21
Deficiency: "The Clean Air Act standards for PSD for sulfur dioxide would probably be exceeded about two days per year" is a statement which sets the tone for the entire DES. "About two days" is a dimension which is useless to someone reviewing the report. If it means two or more days then this is a violation of CAAA'77, if less than two, it is not a violation.

④ Comment: The 1978 state legislative support for the oil port of Port Angeles reflects the belief of the Seattle-Tacoma residents that the port will eliminate tanker traffic to inner Puget Sound and through the San Juan Islands. All the impacts on Clallam County are stated for an oil port which will not reduce tanker traffic to the refineries and may actually increase petroleum traffic if distillate or Bunker fuel is barged to Port Angeles. The air quality and oil spill impacts on Clallam County should be modeled and reported in the DES for a 1,200,000 bpd through put. Unless a 1,200,000 bpd port can be legally located in Clallam County the deceptive tactics now being used to gain undeserved support for oil transshipment should be stopped.

⑤ Summary: Page 21
Comment: The air quality deterioration cited would be a violation of the Clean Air Act as Amended in August 1977, for sulfur dioxide. On pages 3-4 and 3-5 under "operation Phase" it is claimed that such violations will not occur more than once each five years. It is believed that the statement on Page 21 of the Summary is the more nearly correct. Information on which it was based should be placed in proper section of BLM Environmental Statement.

⑥ Sec. 3.1.1; Page 3-1
Omission: "The proposed project will have no significant effect on climate" is a rash statement unsupported anywhere in the DES. Effects on climate by major pollution sources such as an oil port occur some distance down wind. For this instance the area affected is Sequim, Kitsap Peninsula and the Puget Sound Non-attainment area. The Sequim climate is distinctive enough that much of the area has been developed because of the low precipitation rate and increased sunshine. See "Washington Climate EM 3708 Dec. 1972, Cooperative Extension Service, Washington State University". Numerous references show much larger areas than the Sequim Prairie have had increased rain fall due to upwind changes in particular, heat or other pollutants. See Weather and Climate Modification, National Research Council, National Academy of Science, 1973 or "change in the Weather" by Fitzhugh Green.

⑦ Sec. 1.2.2.1; Page 1.2-2
Omission: The EPA challenged data for the 3rd and Chestnut $SO_2$ monitor for January thru March, 1977. The monitor was then out of service until December, 1977. Reading from January 1978 thru June 1978 are considered valid readings. After exceeding the Federal Primary standard in June, 1978, monitoring was stopped until December. Report #EPA 910/9/78-049A Dec., 1978 "Washington Environmental Quality Profile 1978", page 5, Figure 2 shows the Health Stands for $SO_2$ were exceeded an average of 6 days per year for the years 1974, 1975 and 1976. The 3rd and Chestnut monitor location is in a fully developed residential area and would measure $SO_2$ levels seen by a significant portion of the Port Angeles population. Meteorological data from the town of Port Angeles, not from Ediz Hook, should be used in $SO_2$ pollutant modeling.

⑧ Sec. 3.1.2; Page 3-7
Omission: There have been several readings on the zone monitor in Sequim of 0.07 ppm. (70 ppb.) and has approached the 80 ppb. standard. The Reid Vapor Pressure selected for this study makes discussion of HC and $O_3$ useless. Once the correct RVP is used additional modeling should be done for Sequim and other downwind locations.

⑨ Page 1-35
Omission: Speaks to storage to be added at Clearbrook, Minnesota to be built by someone else other than Northern Tier. The storage capacity spoken to is for one million barrels. Page 3-57 states the additonal storage to be built at Clearbrook would result in an increase of annual emissions of hydrocarbons from ONSHORE STORAGE TANKS of 85 tons per year. The ONSHORE STORAGE for Green Point with 25 tanks would be 13.6 million barrels with hydrocarbon yearly emissions in amount of 85 tons x 13.6 million assuming formula given on page 3-57 is correct.

⑩ Sec. 2.1.1.2; Page 2.4
Omission: Wood is a "dirty burner" and wood burning is widespread in Port Angeles. This is a major baseline source and should not be ignored.

⑪ Sec. 3.1.2; Page 3.2
Deficiency: Maximum length of time for ACUTE DUST PROBLEMS and effects on outdoor living habits of current Green Point residents. How will residents be compensated for dust problem damage to yards and/or paint damage and cleanup problems. Impacts for all const. phases.

⑫ Sec. 3.1.2; Page 3.2
Deficiency: Port Angeles has been notified by the Washington State Department of Ecology that it is not meeting clean air standards. The BLM-DES does not speak to the problem of how to transport men, material, and eqipment to the marine terminal site without creating a significant deterioration of the city's air quality, especially downtown.

⑬ Sec. 3.1.2; Page 3.2
Deficiency: No baseline data is presented on the number of people in the area with respiratory problems that would make them unusually sensitive to oil port and tanks form pollutants. There are many residents of the Sequim area who moved to clean air for relief from respiratory ailments or allergies. Impact

---

CONT

⑬ data on the health of humans is lacking. Some state and federal air quality regulations were written recognizing that even when there might be adverse impacts on the health of some humans. The health basis for the air laws or standards should be covered in the FEIS.

⑭ Sec. 3.1.2; Page 3.2
Omission: State and local and federal air quality standards are ignored during construction. Fugitive dust levels are ignored. For traffic alone a 5 mile pipeline section and pipeline construction and storage facility construction SAI estimated more than 12 tons a day during peak periods. How can this be ignored?

Sec. 3.1.2; Page 3.2
Omission: Discussions at public hearings indicate NTPC did not consider the needed watering trucks in their calculations. This is a serious omission considering the amount of watering need for soil compaction to 95% at the tank farm and pipeline and need to prevent fugative particulate in the summer construction.

⑭ Sec. 3.1.2; Page 3.3
Deficiency: Mathematical modeling studies have not been undertaken to obtain quantitative estimates of air quality impacts during construction. Significantly, the provisions of the CAAA of 1977 regarding PSD exempt such transient construction activities from consideration for allowable air quality increments. It does not exempt them to violate ambient standards. The exemption applies only if the construction emissions would exceed PSD increments but be within standards. There is a TSP non-attainment in Port Angeles, a serious $SO_2$ problem (probably at non-attainment levels), and areas that may exceed dustfall standards. The massive $NO_x$ emissions during construction could well cause $NO_x$ violations. It is absolutely essential that construction emissions be modeled. Construction odor and noise laws and violate standards protecting degradation of Class A water.

⑮ Sec. 3.1.2; Page 3.3
Deficiency: Page D-9, Appendix D, Engineering, "West Coast Deepwater Port Facilities Study", June 1973, by U.S. Army Corps of Engineers states that: "(1) Fixed berth. Waves higher than six feet and winds with a velocity of 24 knots and over will suspend berthing and deberting operations, whereas currents not parallel to the axis of the berth will increase the difficulty of these maneuvers. Wind speeds in excess of 37 knots will suspend unloading operations because of the forces on the unloading equipment." Also, a problem peculiar to Port Angeles harbor is that during storms break up of log booms may make it impossible for tugs to maneuver tankers into or away from piers. One reason for the tanks form is to permit pumping to continue when tanker arrival or unloading is interrupted. When supplies of crude are reduced in the tank form and several tankers are awaiting unloading because of labor, operational or weather conditions, the true worst case emission situation will develop. All piers will be used as rapidly as possible until the tankers are unloaded, with preference probably given to the larger tankers. More than once a year, continuous use of both piers for over 100 hours could be expected. Therefore, the higher wind speeds should be excluded from tanker stack emission dispersion models, since unloading would not be performed under those adverse conditions. Modeling should be performed for post-storm conditions when a waiting line of tankers will unload at maximum rates in what is usually calm wind conditions. Allowance for suspension of berthing should be clarified in the FEIS.

⑯ Sec. 3.1.2; Page 3.3
Comment: The projected port call frequencies are probably incorrect. As pointed out in the Upper Midwest Crude Oil Supplies Problems and Alternatives, the total Aslakan through put is now estimated at 1.2 mbpd. The west coast can use 700,000 bpd and the Sohio project can use 500,000 bpd. There will be only 100,000 - 400,000 bpd left for NTPC or 25% of the 1.2 mbpd, not 50%. This table also does not take into account the segregated ballast per ship. For example the 300,000 dwt class have only 11% segregated ballast. This would account for 108 tons more of HC emissions for the lowest through put of 709,000 bpd.

⑰ Sec. 3.1.2; Page 3.4
Deficiency: This complex mechanism omits several well established reactions of $SO_2$. In view of the fact that the annual exhaust emissions from tank stacks are 2,539 tons per year of $SO_2$ and 461 tons per year of $NO_2$, $SO_2$ is a pollutant of consideration importance. It will react with every atomic and radical species in the photochemical mechanism and with $O_3$ as well. Why is the photodissociation of $O_3$ omitted? It has a much higher extinction coefficient than $H_2O_2$ (reaction 21) and absorbs light at longer wave lengths.

⑱ Sec. 3.1.2; Page 3.4
Mitigation: Use of very low sulfur content fuel by tankers in port would, if accomplished, be a successful mitigation for sulfur dioxide. A permit for the port could be assessed with the provision that only 0.5% sulfur content fuel be used in port. Unless the enforcement agencies and procedures are more successful than historically proven, more and stronger mitigations are needed. Two measures submitted for discussion are (1) Have a bonnet over the stacks of the tankers and process the flue gases through scrubbers, bag houses, precipitators, catalytic, converters or whatever is necosary to remove $So_2$ and $NO_x$ and TSP. (2) Have flue gas monitors on booms to insert into the tanker stacks to actually measure pollutants.

Sec. 3.1.2; Page 3.5
Omission: Annual geometric mean concentrations measured at the police station monitor (moved in 1976 to city light building) were slightly above the WDOE standard of 60 mg/m$^3$ each year 1971-1976. Points to be made that 1970 and 1977 also had violation. Violations from 10-28% over the standard should not be considered slight. 60 mg/m$^3$ is not only a WDOE standard but also a federal secondary standard. Although fugitive sources are difficult to model they cannot be ignored.

⑲ Sec. 3.1.2; Page 3.6
Omission: $NO_2$/NO ration assumption is not given; the effect on changing $NO_2$/NO ratio due to new vehicle emission standards is not evaluated; $NO_2$ emissions from construction is not evaluated in terms of existing standards (not exempt); $NO_x$ is not evaluated for visibility reduction.

⑳ Sec 3.1.2; Page 3.6
Deficiency: The rationale for worst case for tanker hydrocarbon emissions overlooks several factors: The assumption that ballast emissions will be the worst case hydrocarbon emissions is incorrect. The worst case will be in the event of an oil spill where 15% of the oil enters the air within the first two hours. The second worse case will be purging. It is stated that purging will not be done in port except in an emergency,

---

CONT

⑳ a situation which may be under control of the ship's captain rather than Northern Tier. Further, it is indicated that purging might occur once the tanker is outside the harbor.

Sec. 3.1.2; Page 3.6
Deficiency (continued): This is just the right distance from Port Angeles and Sequim for maximum air quality impact. The worst case emission schedule should be computed for an oil spill of one tanker compartment (60,000 barrels) and for purging of the largest size tanker in port and 10 miles from port. The third worse case for ozone, photochemical exidant or smog formation would be for two tankers to take on ballast at the same time, an event which is likely to happen more than once per year. EPA - 450/2-76-016 Aug. 1976, Page 18 of "The Health Implications of Photochemical Exidant Air Pollution to Your Community" reports that the most effective means of reducing levels of oxidants is through control of hydrocarbon emissions. Since there is reportedly 2772 tons of nitrogen oxides per year emitted from existing Port Angeles sources, the third worse case model of two ballasting ships providing the maximum hydrocarbon emission would seem to apply. Specifically, if two large tankers took on ballast from 6:00 a.m. to 9:00 a.m., under temperature inversion of approximately 1,000 feet with full consideration of the dispersion blocking by the nearby mountains, the tiny Port Angeles, Sequim air shed would be in violation of existing or planned air quality standards. During the 6:00 a.m. to 9:00 a.m. time interval, it is estimated with a Reid Vapor Pressure of 8.0 that there would be over 27,000 pounds of hydrocarbon emissions.

㉑ Sec. 3.1.2; Page 3-7
Comment: No mention is made of ship stack blowing. No mention is made of the steam emissions. These could effectively block the view of Victoria from downtown Port Angeles (the stacks of each ship will be near 100,000 acfm). WAC 18-04-040(1) & (5) is not even mentioned let alone evaluated. (5) emissions of air contaminants or water vapor detrimental to persons or property. No person shall cause or permit the emission of any air contaminant or water vapor from any source, including any air contaminant. No person shall cause or permit the emission of any air contaminant or water vapor from any source, including any air contaminant whose emission is not otherwise prohibited by this regulation, if the air contaminant or water vapor causes detriment to the health, safety, or welfare of any person, or causes damage to property or business. The tanker emissions, water vapor, could be detrimental to downtown tourist business and reduce view property value at some locations. It would appear that during unloading a ship could also be in violation of section (1)(a) and (b) 40% opacity and grain loading of .2 gr. SCFD or 20% opacity and a grainloading of .1 gr./SCFD. with emissions of 42.4 lb/HC and 100,900 ACFM 300°F there appears to be a violation.

Page 3-7
Comment: It is assumed in the DES that $O_3$ levels will decrease. "Ozone & light hydrocarbon measurements in the Phoenix Arizona" (Westberg, Robinson, Zimmerman 67 annual area meeting, state it can also be shown on the basis of laboratory data that the amount of $O_3$ generated by $NO_2$ and the hydrocarbons is not only a function of the concentration of these reactive components but also in the ration of their concentrations. It is on this basis that Chas and others have argued that automibile exhaust controls that lowered the emitted hydrocarbons were much less effective in reducing the Los Angeles photochemical smog problem because hydrocarbon control has gained at the price of an increase in no emissions. The resultant no-hydrocarbon ratio is then larger than the pre-control value and is suspected, on the basis of laboratory studies, to be a situation capable of supporting efficient atmospheric $O_3$ product catalytic converters increases the sulfuric acid mist. Since changes in auto emissions is mentioned it is an omission not to mentioned the two above mentioned detrimental effects.

㉒ Sec. 3.1.2; Page 3.7
Mitigation: The selection of a Reid Vapor Pressure of 4.0 psia nigates all computations for hydrocarbon emissions, both tanker and tank farm. There is ample documentation showing 8 to 12 psia as typical "Reid Vapor Pressures". An oil port receiving oil from all over the world would be expected to receive oil with RVP of 12 or more, and certainly with a True Vapor Pressure of more than 11.1 psia. Therefore, in accordance with standards for new source emissions the tank farm would require a vapor recovery system as a mitigating action. A weighted average computation for the RVP conceals the worst case for hydrocarbon emissions. For example, the formula on Page 44 of the Technical Document for this DES has the term $\left(\frac{P}{14.7-P}\right)^{0.7}$ as a multiplier in computation of storage tank standing losses. P represents the true vapor pressure, which is essentially equal to the Reid Vapor Pressure at the temperature expected for North. Slope Crude. With P=4 the term becomes 9.50. With P=12, (not an unlikely worst case reading), the term is 2.82. This means the estimates of hydrocarbon emissions should be over 500% higher than those used in the DES. Reid Vapor Pressure references as high as 12 psia were found documents available to the Clallam County Task group.

㉓ Sec. 3.1.2; Page 3-7
Omission: Since the HC emissions have been underestimated by a factor of 5 the statement that emissions from the project would be substantially smaller than those from existing sources is questiond. The statement that effect on visibility would be evident only to some one in the park looking toward Port Angeles is incorrect. Major impacts on visibility would be looking from Sequim-Dungeness, San Juan Islands, or Victoria, B.C. through the haze toward the snow covered peaks in the Olympic National Parks.

Page 102
Deficiency: It is claimed that adverse weather is incorporated into the model as a random variable. No definition of adverse weather is provided or any hint given as to what extent the random variable changed the model.

Sec. 3.1.2; Page 3.7

Omission: At the Sequim location there is $O_3$ data for 4-78 -- 7-78 showing maximum values of .07. A similar trend is indicated in Port Angeles at a 2nd and Washington monitor, indicating levels at .04 in Feb, 1974. This corresponds well with the Sequim Data so we could expect summer concentrations at .07 - .08. Some argument has been presented as to the validity of the Sequim data because it is near HWY 101. The majority of Sequim is within two blockes of HWY 101. PSD guideline state for vehicle traffic 1,000 VPD. The sampler should be 20 meters from the road. For Cedar Street this criteria fits well and for traffic flow from 1,000 to 10,000 it should be from 20-250 meters away. The sampler is within this range. This data should not be ignored. This data is representative of the general area (Sequim) concerned.

126
CONT

Sec. 3.1.2; page 3-7
Deficiency: Page 16 of this DES's technical document claims that there is no hydrogen sulfide in crude oil below 200° F. Perhaps this is a reference to one particular sampel of crude There may be thousands of ppm of $H_2S$ to crude oil in the DES all references to odors should be restated. Further, since fatalities can result from as little as 100 ppm of $H_2S$ the hazards hould be subject of complete coverage for fatalities as well as odors.

24 Comment: The impact of discharging oil contaminated waste water at the tank farm is not openly discussed. There is a vague statement on air quality to the effect that there will be large emissions of hydrocarbons if substantial amounts of waste water is processed. This is not a full disclosure of information in layman's terms. By use of information available in other BLM reports it was estimated that up to 2,790,000 gal/day of waste water will be discharged to Siebert Creek from the bank farm. Since this is water from oil tanks it should not be permitted to reach Siebert Creek or the Strait of Juan de Fuca. A possible solution is to pump the water to a separate tank at Green Point and then return it by separate pipeline to the port for use as ballast water.

Sec. 3.1.2; Page 3.7
Question: CBI studies. Four points should be made. 1) these CBI studies were 1978 so have had insufficient time for evaluation and field application, 2) CBI makes storage tanks and socould produce biased results, 3) The CBI/Sohio studies are on a mock up rather than on field tanks (per evaluation of meths for measuring and controlling H5 emissions from petroleum storage tanks; EPA and 4) SAI reported studies (in their report for the BLM NTPC EIS) showing API underestimating emissions 38% of the time. Quotes from the above EPA evaluation: "Advances in roof design have been directed at improved safety, durability, ease of construction and low cost. No experimental data were found to indicate that any particular design (whether new or old) was effective at controlling hydrocarbon emissions than any other design." In discussing the variety of newer flexible seals: "however, no experimental data were found indicating any particular seal was superior to any other in controlling emissions. Claims to seal effectiveness are based on appearance and apparent closeness of fit between the seal and tank wall." and as for best technology: "vapor recovery offers the potential for positive control of hydrocarbon emissions from storage tanks".

25 Sec. 3.1.2; Page 3.7
Deficiency: On the average about one pound of HC will be emitted for every 1000 gallons of Ballast water. The EPA oil disposition study (EPA: 910/9-77-044) uses a fixed roof tank emission calculation. This takes RVP & temperature into account. So is more reasonable than ERT's figures $F_{c0} = \frac{2\text{-}25PV}{10{,}000} K_t$ ($K_t$ = 23 turnover rate, P=true vapor pressure, V= volume pumped into tank). For example if we use a more realistic vapor pressure of 4.1 RVP with the increased oil temperature which Alyeska says they will use "Summary Report - Air Quality for TransAlaska Pipeline Terminal" submitted to the Alaska Dept. of Environmental conservation) we increse emissions 147% for the phase II temp. emissions and 244% for phase three temperatures. ERT states 16,300 lb/ eve (in error their chart lables it $10^3$ gallons) for HC emissions for 300-327,000 dwt. This equates to 39,772 lb/event using a realistic RVP and taking into account that the oil temperature will rise. SAI states ballasting for this class will be 4.7 hours compared to 8.49 or 1.8 times the concentrations.

Sec. 21.17: Page 29.
Mitigation: Predicts relatively high $NO_x$HC , and CO pollutants for on-road vehicles. The possibility of railroad service being continued to offset air pollution should be examined. The railroad should carry freight with less air pollution per ton/mile than trucks. Since the railroad owner is a member of the Northern Tier Consortium the reduced air pollution would offset to some extent the increased pollution from the oilport. It is understood that over $2,000,000 in State or Federal funds is being sought to keep the railroad operating.

26 Sec. 3.1.3 Page 3-8
Question: It is stated that Washington State Noise Standards will be exceeded during the construction phase. There is not full and clear coverage of the noise to be expected during the operation phase. Page 3-10 states that the Washington Standard of 47dBA would be equalled at one location, without specifying location. Presumably the pumps would be the noisiest item at the tank farm but there are agitators on the tanks which are not mentioned as to noise level.

27 Page 8-106:
Question: "Tank design features would minimize hydrocarbon release." What is the tank design? Are floating roofs included in the design?

28 Page 8-106
Question: What level of "incremental" increase in hydrocarbons from tanker offloading? Please quantify "incremental increase".

29 Page 8-103
Ommission: A statement in the DES, regarding the Kitimat projects declares that the unloading facility will introduce major new hydrocarbons. No such qualifying statement is made regarding hydrocarbon level introduced to P.A. by NTPC under air quality summary, page 3-2.

30 Sec. 3.1.2-8 page 3-5
Question: What is the definition of "Strong" under column headed "inversion strength."? The column "Average Time" shows the longest period is 24 hours for the "Worst case". What condition would prevail in a "strong" inversion lasting 36 hours? 48 hours? 72 hours?
Did the weather data from Ediz Hook contain a complete report on inversions?
Why was only 5 years of weather data used? Were the 5 years consecutive? Which years?
To determine the true pollution figures, you need weather data from other locations. Weather data from Ediz Hook is only pertinent to the location of the instruments used. Water surrounding Ediz Hook on three sides contributes to a unique climate, vastly different than in the Port Angeles area.
Why has there been no mention made the possibility of the pollutants being air-borne to King County and other places? Why does it say in the summary on page 2, section 3, that the ozone level in the vicinity of Green Point might be increased by 10% while in the same section, page 7, it says that the ozone levels at Green Point will be raised by 20%?
According to EPA's Washington Environmental Quality Profile of 1978 only two counties, Clallam and Pierce, do not meet air quality standards for Sulfur Dioxide. Why was this not mentioned in the DES?

31 Page 3-6
Ommission: The serious ecological problems of acid rain and effect of hydrocarbons ommissions on human health have been ignored by the BLM. ACID RAINS: Acid rains and snows have well documented unfavorable effects on aquatic life in lakes and plant life in forests.
Chemical and Engineering News, page 29, Nov.22, 1976;
Environmental Science and Technology, 12 580; 1016 (1978)
Seattle Times, Mar. 8, 1979.

CONT 31 The potential decimation of fishlife in our lakes and streams and the retardation of forest growth will have a serious effect on our industrial economy, tourist business and quality of life on the Olympic Peninsula. Acid rains result from the oxidation in air of the pollutants, $SO_2$ and $NO_x$. The products are sulfuric and nitric acids. The air is cleansed of these corrosive compounds by rain and snow and fall to the ground as acid rain. Extensive studies of its deleterious effects have been reported. Some of the findings are:

1. Decline in fish population in Norway has been correlated with acidity of streams and lakes, and trout and salmon are seriously affected by pH's less than 5.5 Newly hatched fish are most vulnerable to acid. The pollutants originate in England, Europe.
2. In Sweden about 10,000 lakes have been acidified to pH's less than 6. 5,000 of which are below pH 5 and fishless.
3. In the Adirondack Mountains of New York, 51% of the mountain lakes have a pH less than 5; now 90% of these lakes have no fish. During the period of 1929-37 only 4% of these lakes has a pH of less than 5 or were deviod of fish. Fisherman are no longer finding this region the paradise it once was. Tourists avoid the region for this reason.
4. Forest growth has been reduced in southern Scandinavia and in the northeastern U.S. between 1950 and 1970. Norman Glass of EPA estimates that forest production is off 14%. Seattle Times, March 8, 1979. The reason is uncertain but acid rain is a suspected cause. In this connection, however, laboratory and field tests have shown that acid precipitation can affect the germination of conifer seeds and the establishment of seedlings.

The problems of acid rain cannot be ignored. The Northern Tier facility will increase the burden of $SO_2$ for the area by 20%, and of $NO_x$ by 11% at the 933,000 barrels/day level, according to the data of Table 3.12-6. Local residents know of no acid rain measurements to have ever been made on the Olympic Oeninsula, nor has any modeling data been obtained. An approximation method for calculating rainfall pH on a multi-state scale has, however, been developed by Pacific Northwest Battele scientists. Along with the lowland areas the pH of the Olympic National Park's rivers and lakes should be taken and the pH of its rains and snows monitored. Then with the Battelle approximation method it should be possible for Northern Tier to forecast the future acidity of these bodies of water caused by the $SO_2$ and $NO_x$ pollutants. Pacific Northwest Laboratory Annual Report for 1977. (PNL-2500PT3 p. 1.23, Feb. 1978.) When the pH of these lakes and streams reaches 5.0 they will no longer support fish. For us on the Olympic Peninsula, this acidity hazard is fully as important as the primary pollutants, $SO_2$ and $NO_x$.

32 HYDROCARBON EMISSIONS:
It is stated on page 3-6 that "hydrocarbons by themselves do not prove to be a health hazard." This statement reveals a careless disregard of the facts. It may apply to the aliphatic or saturated hydrocarbons, but it does not apply to the aromatic hydrocarbons. And since 47% of the whole Prudhoe Bay crude oil consists of aromatic hydrocarbons, the impact statement must consider the effects of these compounds on the health of the community. Benzene, soot, tars and oils are listed among known chemical carcinogens. Because benzene, the simplest of the aromatic hydrocarbons, is on the list, it is highly likely that all of its derivatives, as well as all of the condensed ring compounds, present in the Prudhoe Bay crude oil, are potential carcinogens too. While these compounds are much less volatile than the saturated hydrocarbons used for gasoline, nevertheless they gain access to the atmosphere from spills on the water, on the land, and particularly at the tank farm. Hydrocarbons have been indicted by some as a possible cause of lung cancer. Port Angeles will receive a 36% increase in saturated hydrocarbons, but the cancerous aromatic hydrocarbon content of the air will be increased many-fold. A recent study found that lung cancer deaths in Texas, especially in the industrialized Houston area, had increased by 53% between 1969 and 1976. Environmental Science and Technology, 12 1356 (1978) The incidence of lung cancer is significantly higher in Texas than in the U.S. as a whole. The area is primarily in the petrochemical industry. While smoking may account for about 50% of the lung cancer cases, the question now is, can rapid population growth and industrial expansion account for the remaining 50% This the University of Texas does not know. There are several unknown factors regarding the health hazards of air pollutants. It is stated on page 3-6 that the saturated hydrocarbons are harmless, but what is not known is the toxicity of their oxidized compounds. These products are aldehydes and ketones and they would be expected to be of considerable greater toxicity than the hydrocarbons themselves. Furthermore, these compounds behave more like free radicals, and there is one school of thought that regards free radicals in almost any form as potential carcinogens. Science 202 37, 6 Oct., 1978. The remaining hydrocarbons, even without oxidation, are possible carcinogens, especially those in the aromatic and condensed ring systems. The problem here is the same as with that of radiation - what is the threshold? How dangerous are low doses? These matters have recently been discussed. Science 203, 522, 9 Feb. 1979. At the present time no one knows whether or not a threshold exists. A group correlated lung cancer deaths in twenty counties, including the U.S., which have varying degrees of air pollution. Environmental Science and Technology, 12, 1356 (1978). From this study the group concluded that lung cancer as indexed by benzopyrene correlated with lung cancer deaths even when cigarette smoking was eliminated as a factor. The group calculated that a microgram of benzopyrene/1000m$^3$ of air appeared to be associated with a 5% increase in the incidence of lung cancer. They also concluded that a 60% reduction in air pollution might result in a 20% reduction in lung cancer. An insidious property of the Prudhoe oil is its large fraction of aromatic hydrocarbons (48.5%) all of which are probably cancerous to man. As already stated, benzene is a carcinogen to man and the benzopyrene mentioned above is carcinogenic at less than one part per trillion parts of air. The residents of Clallam Coutny, particularly those of Port Angeles and Sequim areas, should be appraised of the potential hazard of these hydrocarbon emissions. A thorough treatment of this aspect of aromation hydrocarbon pollition must not be omitted from the Northern Tier Environmental Impact Statement.

33 Sec. 2.1.1 15-1
Defiency: Population: Figure 21.1.15-1 should be up-dated if possible because retirement influx has increased very considerably and this is pertinent to allowing increased air pollution: the compromised cardio-respiratory status of the aging population means human health effects at lower levels than anticipated by the EPA's recently more relaxed standards. The proportion of over age 50 years population in Port Angeles and in Sequim, less than 10 miles of and downwind from the tank farm should be ascertained and recorded.

34 Sec. 1.4
Defiency: For the diesel emergency generator: what is the past experience with frequency of use? Duration expected in hours of use per year? How frequently is their functional state tested? What is the noise factor at the site boundary? The air pollution level from diesel generator? What is the size of the diesel storage tank and how much of its vapor reaches the air?

35 Question: Will there be burning (on right of way) of brush or crops? Discuss control - if any- of air pollution from grading and other pipeline laying procedures.

36 Sec. 1.4
Deficiency: What type of paint will be used for the tanks at the tank farm and what amounts of solvent and other toxic materials will be released to the air from this source?

37 Sec. 1.4
Omission: Describe the emergency diesel generator: how big, how noisy, what emissions: Give the latter qualitatively and quantitatively. How often is this equipment operated aside from emergencies, to check on performance?

CONT

38 Deficiency:
Future Environment, page 2-154 Air Quality: since we are in a fact a SO2 non-attainment area (see page 2-5, also the EPA publication Washington Environmental Quality Profile, 1978 Fig. 1, Air Quality Status Map-By-County), it will have to be anticipated that air quality will be brought into line with provisions of the Clean Air Act. The EPA has already been petitioned to take formal action in this regard.

39 Sec. 1.4
Omission: What is meant by "to minimize hydrocarbon vapor emissions" when there can be no vapor recovery system as the floating roof descends exposing an oil-wet wall of the tank? Please describe each major type of oil to be handled with regard to chemical nature of all volatile hydrocarbons and the proportion of each in the vapors at 100 degrees F., hydrogen sulfide and other contamination odorants. and give the Reid vapor pressure for each of the major crudes. What will hydrocarbon vapor losses be from standing tanks on a hot windy summer day, assuming that Alaskan oil will be a full production and emerging at Valdez with a temperature of about 105 degrees F.? What will vapor losses be if this is combined with tank draw-downs accompanying maximal delivery for the FULL size project from tank farm to cross-continental pipeline?

Deficiency:
Visual Resources: Add consideration of view of the Olympics from distant points as Seattle and Canada and how this would be affected by suspended hydrocarbons and other pollutants in the air. Include view of the sky, currently blue most of the time, and the gray color of hydrocarbon containing smoggy skies, the brown color of nitrogen oxides floating above. Include the aesthetic value of looking down from Olympic National Park on a smoggy Port Angeles and Sequim-Dungeness valley. Include olfactory effects in the sensory impacts of the project. Include loss of sunlight energy falling on the earth and the generally reduced visual and sensory effects of this.

Page 2-48
Deficiency: Dispersion Potential: EIS should include that the influence of terrain and low mixing heights from the marine climate will accentuate the air pollution especially for Port Angeles and to a somewhat lesser degree for Green Point. The mountains rise relatively close to the sea at Port Angeles and when winds come from the north pollution is trapped much as it is in Los Angeles.

40 Page 2-48
Comment: Include Port Angeles in the $SO_2$ air quality violation areas (see p. 2-5). On very limited sampling, less that once a week, sulfur oxide maximum for 24 hour average has been found to reach 551 (State standard being 260 and Federal standard 365 for this finding). The one hour maximum has been found at a maximum of 2,593 with the comparable state standard being 1048 not over once per year.

Note that the high ozone readings in the Seattle/Tacoma areas can be influenced by hydrocarbons released at Port Angeles and Green Point with sunlight here in the "sun belt" acting on the material prior to its arrival in the metropolitan areas.

41 Page 8-10; 8-19
Question: What data base was used to assume meteorlogical conditions at Cherry Point and Burrows Bay are very similar to Port Angeles and the downwind area? The Sequim-Dungeness area is meteorlogically unique on the West Coast (i.e. driest spot north of San Diego on the West Coast).

42 Sec. 4; Page 8-29
Question: The BCM-DES declares that the highest concentration of $SO_2$ would occur several miles to the east. How many miles (or range of miles) are "several"? What is the impact on Port Angeles?

43 Deficiency: What will the effect of the 1% sulfur fuel oil have for the 1.283 million bpd throughout on air pollution in Port Angeles harbor and in Olympic National Park as compared with the figures used in the tables in this draft? (Didn't the tables assume this when they were drawn up?.) What would the values have been if this assumption were based on the usual bunker fuel oil?

Why is it deemed more important to avoid the Yellowstone River in Montana than the Dungeness River, the big and little Quilcene rivers, the Duckabush, the Dosewallips, Nisqually and Hama Hama in Washington? These Washington rivers all lead immediately to estuaries with wildlife refuges or food production or both. Was the decision on the Yellowstone environmental or political?

44 Page 1-52; item 27
Deficiency: It appears that cargo tanks may be purged 10 to 20 miles from Port Angeles harbor. This will be in the Straits, in an area where oil can be carried to Canada, and where currents carrying materials in a net-eastward direction can deposit the tarballs back towards Port Angeles. Please describe the areas to be contaminated in more exact and quantitative terms. For ballasting to the extent of 20% in Port Angeles harbor, how much oil fumes will be released to the harbor as a result? Why is it not a requirement that tankers have seggregated ballast tanks?

Deficiency:
Climate: the climate at Green Point differs considerably from Port Angeles and should be separately described. Rainfall is about 17 inches as compared to 24.6 at Port Angels. Wind patterns will also differ. Background air quality at Green Point is far better than at Port Angeles and the increment for significant deterioration will accordingly be a good bit smaller. Where is the background monitoring year round for this area? The greater amount of sunlight at Green Point will no doubt affect conversion of hydrocarbons to oxidants. In the absence of full air quality baseline data for both Port Angeles and Green Point worst-case assumptions must be made to protect the public interest. Mixing heights for Seattle would not be applicable for choosing mixing heights. A particular concern is distribution of air pollutants over Olympic National Park, Port Angeles and Sequim, such as hydrocarbons, nitrogen oxides, sulfur oxides , photochemical oxidants and particulates. Oxidant transport to the Seattle area which is a non-attainment area, would be expected within the 36 hour transit time set by EPA for evaluation of this type of pollutant. Since benzene is present in crude oil, is a known carcinogen and very volatile, therefore important to human health, the amount capable of release to the atmosphere and its concentrations and trajectories should be included. Baseline data should state the leukemia and cancer rate for Clallam County and a closer survey should be made in Sequim and in Port Angeles for incidence of these disorders so that effects of the project may be properly assessed.

Page 2-4
Deficiency: Include Seattle as a non-attainment area (see above). It is generally recognized that sulfur oxides contribute to acid rain at great distances and the extent of fallout from this should be stated and mapped.

CONT

45 Comment: It is incorrect that Port Angeles exceeds air quality standards only for particulates. The sulfur oxide standards have been exceeded on the few occasions they were measured. (See page 2-5). It is a gross distortion to imply that this condition occurs only immediately next to the source. The air is blue with fumes from the ITT plant particularly, over several miles at times.

46 Deficiency: Ozone has been studied in the Olympic National Park area. The reference should be traced and included.

Comment: Please give the meteurological and air quality monitoring data from Environmental Res. and Technology Inc. in the Technical Addendum for the final EIS.

Deficiency: Operation Phase: add calculation for full size of project. Comments for construction phase above also apply here. Please give full description of mathematical models used in a technical addendum. It must be noted that weather data at the Coast Guard Station is only applicable to the Port Angeles area and not to Green Point. What factors were monitored? Please include a table giving mixing heights for both the port and Green Point. Measurements of mixing levels have been done by ITT Rayonier with aircraft on 7/6/72, 8/2/72, 8/4/72; these values should be included. EPA's "Washington Environmental Quality Profile 1978" shows Clallam County in Fig. 1 as a county not meeint ambient air quality standards, and in Fig. 2 and 3 shows Clallam County exceeding the health standard for $SO_2$

In discussion this report notes that the rain shadow effect of the Olympic Mountains causes a sinking effect of the air on the lee side of the mountains which "also affects the ability of the atmosphere to disperse pollutants. The subsiding air results in the stabilization of an air mass, thus inhibiting the mixing process which normally helps to dilute pollutants". (pp. 35,36)

Deficiency: Please include all available data for background levels on $SO_2$, sulfates, total suspended solids, particulates, hydrocarbons, benzene, nitrogen oxides, and photochemical oxidants with respect to when and where measured, accuracy of the method to measure, and note capability of detection of 5 min. peaks, 1 hour and 24 hour maximum, and frequency of sampling. Then tell us how these would be affected by the operation of the project at the hospital at Port Angeles, at residences in Port Angeles, at Green Point and at Sequim. We believe there is grossly insufficient air quality data, that at least one full year of background collection of data is necessary (which could have been done because proponent has been considering this site for longer than that). The theoretical calculations made, leave much to be desired. The assumptions made should be given in this report as well as the worksheets. For background were actual emissions used or "permissible emissions" unrelated to the real world? Show the applicability of the model to this area. The EPA report referred to above, page 47, states: "The earlier discussion suggested that air mass stability at west coast locations like Port Angeles is likely to be more stable than the Pasquill system would indicate due to marine and subsidence inversion or influences."

47 Table 3.1.2-4
Deficiency: In Table 3.1.2-4 please give the comparable statistics for 1.283 million bpd throughput and the time (as the hours per year or 20% of the time if that is the figure) various emission rates would be exceeded. What are the legalities and law enforcement measures lying behind assurances that fuel used by the tankers would be 1% sulfur type? Physically how is this accomplished? Will the higher grade fuel be added to other fuel in the tanker's fuel tanks or will a separate fuel tank be used?

48 Please document from independent sources (Not NTPC!) data such as existing sources of air pollutants in Port Angels (Table 3.1.2-6)

49 Table 3.1.2-7
Deficiency: Please extend Table 3.1.2-7 to include the 1.283 million bpd throughput.

Deficiency: Please also include measurement of existing air pollution 1.7 miles ESE of the proposed port facility where impact is calculated to be highest.

Deficiency: Please detail the ambient air values (dates, method, and place of measurement) used in comparing the combined effects of background with the proposed project at Port Angeles. Was Was the instrumentation used for ambient air up to Federal (EPA) standards for accuracy or was it a bibbler lacking a necessary temperature control?

50 Comment: What would be the scenario for the worst case: three 300,000 DWT tankers unloading simultaneously under adverse weather conditions for the 36 hour unloading time? Over a 20 year plus lifetime of project this should not be dismissed as occurring infrequently; people breathe even on the less common bad days and cannot suspend this function even once in five years. It is the draft E.S. which is unrealistic when it refuses to give worst case emission rate combined with worst case meteorology. Impact should be studied not only to determine compliance with standards, but also regarding complicance with human health needs which those standards were promulgated to protect.

Question: What is the evidence that air stagnations and inversions in the Port Angeles area last no longer than the 6 hour time used in the valley model? Between June 3 and June 7, 1978, we had a prolonged inversion and air pollution values for sulfur dioxide exceeding 0.40 ppm on 11 hours scattered from 11 a.m. on June 3 to 9 a.m. on June 7, 3rd and Chestnut station, Olympic Air Pollution Authority measurement, listed as Method 13, using more conservative assumptions. Modeling may need to be repeated.

Deficiency: The type of particulates to be released by the project will be petrochemical carbon particles rather than road dirt. Carbon particles absorb sulfur and nitrogen oxides as well as other substances and concentrate these substances from the air. When breathed, the particles adhere to respiratory linings thereby greatly magnifying health effects over effects from pure gaseous pollutants studied in a laboratory situation. The BLM should discuss the impacts of the mix of pollutants on human health for background pollutants and for the changed mix resulting from the project. Such discussion should include the distribution of the mix as well as individual pollutants.

Deficiency: The nitrogen oxides emissions for the 1.283 million bpd project should be compared to existing emissions. Documentation is needed for the source of existing emissions. since nitrogen oxides and nitric acid can have health effects over a short period of time the maximum one hour and maximum 5 min. peaks should be given for ambient air and for project emissions.

126 CONT

Deficiency: Ozone formation due to hydrocarbon emissions is a major consideration for Port Angeles, for Green Point, for Sequim and for Seattle (36 hour travel time is part of the definition of area affected by hydrocarbons according to EPA regulations). Please calculate the pertinent figures for the 1.283 million bpd throughout. What levels of hydrocarbons will be encountered in the harbor, at the hospital, at the tank farm, at Sequim? How much benzene will be released to the atmosphere from the project in Clallam County and what levels may be expected in the above locations? There are persons hypersensitive to hydrocarbons who live in this area, having come here as a refuge from city air pollution. It is not true that hydrocarbons are without health effects. (Read the warning on any can of petroleum distillates if you have any question.) Please give ozone background levels especially in Olympic National Park, but also in Port Angeles. Show the pattern of plumes from the 36 hour travel of the hydrocarbons.

(51) Question: Are the hydrocarbon emissions based on only 20% of tankers without segregated ballast? How is tanker traffic to be limited to insure this proportion will not be exceeded? Why is it not a mitigating measure to require that all tankers using the port have segregated ballast? Will tankers use exhaust from their stacks to blanket oil being unloaded and reduce explosion hazard?

Deficiency: Please include modeling of dispersion for hydrocarbons and for ozone.

(52) Deficiency/Question: Please give technical data and cite references to substantiate a 40% reduction in estimated hydrocarbon losses from the floating roof tanks at Green Point. In the basic underlying studies in how many instances did the tank emissions exceed predicted values?

(53) Question: Please substantiate the validity of using a Reid vapor pressure of 4.0 psia and the temperatures of 97 F summer and 80 F in winter. What wind factors were used in calculating rate of vaporization? What are the Reid vapor pressures for each of the predominant types of oil to be put through? What is the chemical composition by classes of hydrocarbon for each of the predominant types of oil? Include benzene, aldehydes, sulfides, sulphonated hydrocarbons, ethers.

(54) Deficiency: Emissions of ozone levels based on two 190,000 DWT tankers discharging simultaneously is not adequate for disclosure of the probable actual emissions for a 3 tanker berth situation with 300,000 DWT tankers, thus does not provide a look at the full scope of the project early enough in the decision making process to meet the demands of NEPA. Further it should be disclosed what wind speed, mixing height, sunlight factor and temperature assumptions underlie the values obtained by modeling to obtain a value of 0.055 ppm in late afternoon at Ediz Hook and at Green Point.

BLM should document the assertion that emissions would be gaseous and invisible.

Page 3-7
Deficiency: Elsewhere in the document aerosol formation is discussed: certainly every major city can be seen to have grey skies and reduced air clarity. Even forests put off visable hydrocarbon emissions in the form of terpenes: it makes a blue haze. Please in the final EIS give a more accurate account of the visibility effects of the hydrocarbons to be emitted at the point of emission and after sunlight and associated air pollutants act on them. Please present the basis for your statement that reduction of visibility from the project would be "substantially smaller" (p. 3-7) from the proposed project than existing sources. Please give the combined effect of both. Discuss this in terms of a viewer in Seattle, and in Victoria as well as the view from Olympic National Park.

B

ALTERNATIVES

The Alternatives chapter of the BLM-DES generally is inadequate in the analysis provided. Alternatives on the national, state and local level are not addressed thoroughly. International, national and regional areas should be analyzed more completely for possible solutions to the problems of Northern Tier states shortfall and Alaskan crude surplus on the West Coast. All solutions and sites involving Washington State have been addressed in the DES; and, alternate sites within Clallam County for various facilities related to the oilport proposals have yet to be considered adequately.

Insufficient data is presented to form a basis for a decision as to whether the benefits of the project outweigh the potential environmental harm it might bring and whether it is needed at all. In addressing the question of need, the extent of the Alaska North Slope (ANS) crude surplus, the need and ability of refineries in the Northern Tier states to use the high-sulfur ANS crude, the ability of other pipeline systems to serve the Northern Tier states and the use of credits or exchanges to achieve the project objectives (reducing surplus ANS crude supplies on the West Coast and averting projected shortfalls of crude supplies to the Northern Tier states) must be addressed.

① Page 8-7.
Question: The BLM-DES declares: "Without the Northern Tier proposal, the excess West Coast supply of crude oil would continue." By this statement, does the BLM mean to say that no other alternative is valid?

② Page 8-11.
Question: If no mid continent system expansion occurs and the loop Drywater Port is completed, what will occur?

③ Question: What would be the impact of a product line from western Washington refineries to eastern Washington markets as proposed by Mr. Lawrence Bradley, Director, Washington State Energy Office? Would it eliminate the product shortfall projected by some parties?

④ Page 6-1.
Question: The first sentence in the lead paragraph raises a confusing point. If the short-term is the 20-year life of the project, how would the project be able to provide a long-term (more than 20-year) supply of crude oil to Northern Tier and inland states?

⑤ Page 8-56.
Deficiency: Statement: "The alternative route would probably follow existing corridors wherever practical." This language must mean the route is not clearly defined. How then can adequate assessment of impacts be made?

CONT

⑥ Sec. 8.1: Page 8-1.
Error: BLM states that the 4 Corners pipeline could be increased to 140,000 b/d throughput. Oil and Gas Journal, November 13, 1978, page 122, gives throughput expansion possible to 150,000 b/d.

⑦ Page 1-60.
Question: "The applicant must file a statement with the Washington State Siting Council certifying that the proposed project is consistent with the program." Has the statement been filed?

⑧ Page 8-104.
Omission: The Kitimat oilport proposal has been filed under appropriate U.S. Congressional legislation procedures.

Page 8-104.
Question: Has Kitimat now reactivated an application under Canadian National Energy Board procedures?

⑨ Page 8-49.
Question: Clearly define "Public preferences." What public, where, what groups or individuals? How many of the public must present or "preference" before a change is made?

⑩ Page 8-49.
Error: "Noise impacts associated with pipeline construction.... duration would be limited to five days." The "cross sound" pipeline will require more than five days of construction in the Port Williams staging area. This topic should be further discussed.

⑪ Page 8-104.
Deficiency: The Trans Mountain proposal has been filed under U. S. Congressional procedures.

⑫ Page 8-111.
Question: Statement: "220,000 d.w.t. tankers may be available in 1978" for the Jones Act fleet. As of March, 1979, how many tankers over 200,000 d.w.t. are available for Jones Act fleet? How many ships (200,000 d.w.t.) would be needed monthly to move the West Coast surplus around Cape Horn?

⑬ Page 8-113.
Question: Did Explorer pipeline complete expansion plans in 1978? 1979? What is current capacity versus current throughput?

Page 8-113.
Question: What is current status of Amoco extension of Texoma line (Cushing to Chicago)?

Question: What is the current status of potential looping of Capline?

⑭ Page 8-111.
Question: The pressure to expand Capline will come from the construction of the Loop Deepwater Port. DES notes Loop "is not yet under construction" but may be available by 1980's. What is the current construction schedule for Loop? Would Capline looping be expected to occur simultaneously or start after completion of Loop?

⑮ Page 8-112.
Question: "Chicap expansion should be completed in August, 1978." Was expansion completed? What is current capacity? Current throughput?

⑯ Page 8-113.
Question: Was Williams Brothers expansion to allow 120,000 b/d to Minnesota completed in 1978? What is current capacity? Current throughput? Status of current expansion plans?

⑰ Page 8-11; 8-28.
Question: Why will onshore storage require only 140 acres at Cherry Point and 300 acres (p. 8-28) at Burrows Bay? (Yet, p. 8-20 notes 140 acres for onshore storage for Burrows Bay).

⑱ Page 1-4.
Question: Prediction is for 1 million b/d surplus West Coast Alaskan crude oil by 1985. (Predicted by the NTPC paid consultant, PACE.) What do other sources project? What new major finds have occured since the Prudhoe Bay field in 1968 in Alaska to justify predictions of increased Alaskan production? If West Coast refineries retrofit to utilize Alaskan crude, what will West Coast use be of Alaskan crude?

⑲ Page 8-2.
Deficiency: Alternative energy sources must be addressed in order to evaluate justification of projected needs.

Deficiency: Increased domestic production and reallocation of existing crude oil supplies may meet much of the projected shortfall and this must be addressed according to Federal case law. (N.R.D.C. vs. Morton)

⑳ Page 1-51; 1-53.
Question: Table 1.4-22 notes line fill 13,740,000 barrels. Table 1.4-26 notes line fill 12,990,000 barrels. Why the difference of 750,000 barrels?

Page 1-32.
Omission: Did not address energy requirements for 1.29mil. b/d.

Page 1-51.
Omission: What is the cost estimate for 1.29mil. b/d (which would require three berths, etc.)?

㉑ Page 1-7.
Question: How does the oil shutdown in Iran affect these projections? How does Mexican oil availability influence projections?

Page 1-7.
Error: "Two fixed berths" addressed. The proposal should be evaluated at the three berth design and capacity.

㉒ Page 1-4.
Question: Has Canada agreed to continue sweet crude to 1982 at 55,000 b/d? What level of heavy crude?

Error: The proposed maximum throughput of 1.2mil. b/d should have been addressed by BLM.

㉓ Page 1-3.
Deficiency: PACE study under estimates potential throughput of Williams Brothers pipeline for crude oil.

CONT.

㉔ Page 6-9.
Question: Delivery to Washington state refineries would require: 2.1mil. barrels storage at North Bend. ("some other company to build pipeline segment.") Has the impact of storage at North Bend been addressed? Projected costs of this pipeline should be included in the BLM document. Who will construct this segment of pipeline?

㉕ Page 8-4.
Question: For most pipeline segments impacts are "similar to those identified for the proposed route." But, for the Jackass Ridge segment, "major environmental impacts on forest vegetation, wildlife, land use, transportation and utilities would occur." Does that mean impacts are greater? Further explanation is necessary.

Omission: Pipeline segments impacts would "be similar" to those identified on proposed route. Each chapter should be required to be complete within itself.

㉖ Page 8-2.
Question: Exchanges would cause further U.S. dependence on foreign crude. Does not the NTPC proposal also do that by planning on moving approximately 50% foreign crude to be economically viable?

Question: Why would exchanges with Japan "not service to relieve the West Coast surplus"?

㉗ Question: A crude oil shortage could cause initiation of combination of alternatives. What combination? If a combination of alternatives would work, why is not such an approach taken in this Environmental Statement?

㉘ Page 8-2.
Question: The recent U.S. Department of Energy supply/demand study, (February 21, 1979) does not substantiate the assumption that present trans-shipment of Alaskan crude would increase product costs.

㉙ Page 8-3.
Deficiency: BLM should substantiate the claim that 1100 barrels of oil could be spilled at Cherry Point as compared to 887 for Port Angeles.

Deficiency: BLM should substantiate the statement that 939 barrels of oil could be spilled at Burrows Bay versus 887 for Port Angeles.

㉚ Sec. 8.1; Page 8-1.
Error: Unit trains are not addressed because they will not handle 933,000 b/d. Federal case law, N.R.D.C. vs. Morton, holds that federal agencies cannot disregard alternatives simply because they "do not offer a complete solution to the problem."

㉛ Page 8-33.
Deficiency: Pipeline spill frequency is not consistent because different pipeline miles are used. To give a clear picture, all sites must be calculated with a common denominator. (i.e., for 100 pipeline miles)

㉜ Page 8-3.
Deficiency: The BLM-DES states that 914 barrels of oil could be sipped at Freshwater Bay versus 887 for Port Angeles. This statement should be substantiated.

㉝ Deficiency: No comment is made regarding the area affected by oil spills. Yet, it was mentioned for the Low Point site alternative. Both sites should be evaluated upon similar criteria.

㉞ Question: The BLM-DES contains a statement regarding ".... the most desirable oil trans-shipment ports with the onshore pipeline passing around Puget Sound." Does this mean to infer that the around Puget Sound pipeline route is more desirable than the cross Puget Sound pipeline route?

㉟ Omission: The four sites of Cherry Point, Burrows Bay, Freshwater Bay and Low Point should be analyzed as to compliance with local government land use plans and shoreline plans. It is noted in discussion (p. 8-17, Cherry Point is consistent with land use plan). Such information should also be noted in the summary.

㊱ Page 8-3.
Question: Paragraph 2 and 3, Clallam County to the east of the proposed site at Green Point is similar to Burrows Bay in that it has negligible industry and has important marine and terrestrial resources and like Freshwater Bay, the area has relatively little development. Are the impacts at Port Angeles and Green Point equal to or greater than the impacts at Burrows Bay or Freshwater Bay? BLM should further analyze this issue.

㊲ Question: Are there potential onshore storage alternative sites in Clallam County which were not in conflict with the County Comprehensive Plan when the Northern Tier Pipeline Co. initiated its project? Also, there are several sites in Clallam County which better comply with the industrial site standards in effect at the announcement of the project.

㊳ Page 8-4.
Deficiency: Define specifically what constituted "major public and governmental opposition" to Stampede Pass segment of the pipeline.

㊴ Omission: The BLM should quantify and specify what "public opposition" to the Coeur d'Alene route segment.

㊵ Page 8-5.
Question: The BLM-DES declares that "only viable alternatives capable of utilizing West Coast crude oil surplus to meet the demand in the Northern Tier states were given final consideration." Does West Coast crude oil surplus mean Alaskan crude? What percent of total capacity of the Northern Tier states can use Alaskan crude? If they require largely "sweet" crude, is the above statement a valid criteria for sole consideration of alternatives?

㊶ Page 8-7.
Omission: The "no action alternative would foreclose the opportunity of supplying the Puget Sound refineries from the North Bend area" (there is no such line presently existing). Reference should be made to Trans Mountain Co., which has always served Washington refineries. Exchanges with Canada would allow use of the Trans Mountain line and reduce tanker traffic.

CONT.

㊷ Page 6-3.
Question: "The trade off would provide short term economic benefits in exchange for a change of life style with some risks to present and future recreation, commerce and possibly health and safety because of air quality degradation and potential risks of major oil spills, fire and explosions." This sentence speaks mainly to the Port Angeles area. Does the federal government or any other government unit for that matter, have the right (authority) to overrule the local community and subject that community to those risks? Isn't one of the reasons for government to protect the health, safety and general welfare of its people?

㊸ Page 6-3.
Deficiency: The section should note the allegedly illegal procedures exercised by then Governor Evans to add a statement after the final EIS on Washington State CZM policy, without proper public hearings. Notation should also be made that the state CZM policy, without Evans' statement precluded trans-shipment of oil in Washington state. Also the BLM should acknowledge Governor Ray's reasons for requesting removal of the Evans amendment.

㊹ Sec. 1.4.
Deficiency: The cost of contingency plans and measures should be included under costs and reflected in projected tariffs. This cannot realistically be postponed to the construction phase of the project because these costs in addition to all the other costs may help to determine the economic viability of the project.

㊺ Deficiency: Balance of payments problems will not be helped by import of foreign oil, an integral part of this proposal and this should be weighted as a cost of this project.

㊻ Question: It should also give the corporate structure and indicate the financial capability of the NTPC. Will there be marketplace competition for supplies such as pipe or will one of the consortium members by supplying the pipe on a non-competitive basis? What about other aspects of the port and pipeline construction? How will the consortium members and their interests affect the costs of the project and how will those interests affect the ultimate scope of the project?

㊼ Table 1.4-27.
Deficiency: Table 1.4-27 should be reconstructed when more realistic costs are developed.

㊽ Sec. 1.4.
Deficiency: Please include costs for the 1.283 million bpd project. Please also include for all three project sizes, costs for escalation, interest during construction, cost of line fill (13,174,000 bbl.) working capital and debt expenses. Since this is a new line, these costs are relevant in comparing costs of this alternative with other alternatives which are connecting smaller lengths of pipe to other existing already-filled, already-financed pipelines.

㊾ Deficiency: For operating costs give projected costs for power at the time of start up and five years later. Power costs are rapidly escalating and the DES does not seem to allow for this, the base used in all these calculations should be given in a technical addendum. Ten percent contingency seems very low: what is the cost over run historically for other recently constructed pipelines of like size? (Alyeska's overrun? Why should this one be different?) Where is the provision for dismantling at end of project? For compensation in event spills damage water shed or fisheries? For clean up operations in event of spills? For insurance and performance bonds? The numerous stream and river and highway crossings will involve extra expense; how do these figures reflect that? Should the project be delayed by strikes or lawsuits will the cost figures for contingencies be sufficient? Give specifics as dollars per day for delay before, during construction and recent historic record of delays for large construction projects. What special items are likely to cause delay for want of the proper construction material at the right place when needed (specialized construction equipment, materials, skilled labor, etc.).

㊿ Omission: In calculating sales tax, local and county sales taxes should be included in addition to the state sales taxes.

(51) Deficiency: In the Technical Addendum, please include the basic data and the calculations used in the Department of Energy cost analysis which is used as a basis for your figures. The Department of Energy Study was updated and expanded between May, 1978 and the fall of 1978 and we would like to know the point at which the figures presented were drawn. It is hard to believe that list prices for pipe in 1978 are "conservatively high" considering that purchase of pipe couldn't possibly begin for at least a year from that date. Please justify this, giving figures for price of pipe and labor in construction year by year for the last several years.

(52) Question: Where is there provision in cost estimates for costs of mitigating measures which might be very expensive such as relocation of the Port Angeles hospital, compensatory fish hatcheries, requirement for double hulled tankers with all segregated ballast, need to offset air pollution in Port Angeles, double walled pipe under all streams, rivers and other underwater locations, restriction of tanker size from Cape Flattery east and tug escort, use of less than 0.5% sulfur oil for all vessels in Port Angeles Harbor, pick up all fire and explosion hazard insurance premiums in excess of current rates as caused by the project, bonds to cover oil pollution both marine and water table should there be a spill, etc.?

(53) Page 62; 63.
Deficiency: It is a matter of several public records and general public knowledge, that the question of Washington State refinery hook-up is fundamental issue involved with the Northern Tier Pipeline proposal. The proponent does not commit himself to supply of Washington refineries. See page 1-62 and 1-63: In order for the refineries in the Puget Sound area to utilize the system, some other party or parties would have to construct an 80 mile long pipeline.... NTPC does not propose to construct the modifications at this time or construct the connecting pipeline or to operate the pipeline....Recent (3/22/79) amendments to the NTPC proposal (i.e., "Cross Sound pipeline") should require a Supplemental Environmental to be issued. The BLM-DES is very inadequate in its limited consideration of what has now become a major element of the NTPC proposal. The NTPC waited until after all of the BLM public hearings to announce the significant amendment of selecting the new

126 CONT

(53) pipeline route. Because the new route was only mentioned superficially in the DES and because the selection and possible utility of the route will have significant environmental, economic and social impacts, at the minimum a supplemental Environmental Statement should issue addressing a proper evaluation.

Deficiency: The applicant should provide the analysis involved in its selection of proposed transmission corridors and efforts made to avoid scenic, recreational, historic, archaelogical and heavily timbered areas, steep slopes and proximity to highways to minimize conflict between the rights-of-way with present and future uses of the land on which they are located. In addition, the spirit and letter of the National Environmental Policy Act (NEPA) clearly mandate full evaluation of all realistic alternatives. BLM has failed to adequately address alternative pipeline routes. The analysis of the alternate route (cross Sound), is very inadequate. With the amended plans of NTPC indicating this as their new primary route. This inadequacy should require a Supplemental Environmental Statement.

Deficiency: The BLM should include in its analysis:

1. Full disclosure of the process used by the applicant to arrive at the "cross-Sound" crossing proposal
2. Complete and objective analysis of all reasonable alternative routes (at least up to the standard of analysis required by NEPA and SEPA for projects of far lesser consequence).

(54) Sec. 1.1.
Deficiency: Further discussion of delivery facilities to other pipelines is needed. What agreements or contracts exist to allow connections to Glacier, Western Crude, Amoco, Lakehead and Minnesota pipeline systems? Does "access to 50 refineries with a capacity of 3.6 million bpd" define the ultimate extent of this project? If so, please calculate impacts for this figure. If not, why is it mentioned?

(55) Deficiency: The BLM should address, in considerably more depth, the various solutions to the problem of surplus Alaskan North Slope crude oil on the West Coast of the U.S. The TransAlaska Pipeline System is authorized by federal permits to move 1.6 million b/d. New discoveries would be required before an expansion above that level could be justified. West Coast refineries can presently utilize 700,000 b/d of Alaskan North Slope (ANS) crude. Secretary of Energy, James Schlesinger, has promoted government incentives to retrofit West Coast refineries for maximum utilization of ANS amounting to 1.5 million b/d. Additional solutions to the problem of temporary surplus of ANS on the West Coast would include:

1. Encourage industry to design and construct all new refineries to handle ANS
2. Exchanges with Japan and Mexico
3. Restructure of entitlement program to provide incentives to West Coast and Gulf Coast refineries to utilize domestic oil
4. Retrofit West Coast refineries beyond Department of Energy proposals to convert to ANS processing.

Page 8-7.
Omission: The BLM-DES did not consider reallocation of indigenous crude oil.

Deficiency: BLM did not consider increased domestic production, despite significant industry and public coverage of this topic. Oil and Gas Journal articles (1977 and 1978) regarding Overthrust Belt, Montana and North Dakota.

Omission: BLM omitted reference to new U.S. Department of Energy regulations designed to raise domestic production. (Oil and Gas Journal, January 8, 1979)

(56) Sec. 1.2.
Omission: Please give source for the statement that production is declining in "Northern Tier, Rocky Mountain and Midwest regions" in spite of Williston Basin and Southwest Wyoming production, and indicate whether this is for reasons of physical availability or has to do with market relationships and contracts. Give the indiginous production for each of these market areas and the exports out of each of these areas to other markets.

(57) Omission: The issue of continued oil supply on the West Coast and demand for oil of high sulfur content in the northern and central U.S. are pertinent to the cost estimates since a 25 year operating life at full rated capacity is used in making tariff estimates. The EIS should contain in its technical addendum an indication of firm contracts for purchase of the oil.

(58) Section 1.1.
Deficiency: Please specify the market area and indicate what contracts already exist for use of the oil (customers of Northern Tier Pipeline Co.). Specifically what is the firm demand for the high sulfur Alaska product? Further, what is the demand for foreign oil at the anticipated cost of delivery? Please give in a technical addendum the full basis for costs of both types of oil delivered to pipeline customers.

(59) The BLM-DES is deficient as far as data which substantiates the need for the project as comparable to the Canadian National Energy Board Study and as required by the National Environmental Policy Act.

Deficiency: The U. S. Department of Energy recently conducted a supply and demand study for this area. Although at least preliminary findings were available to the BLM last summer, such data was not included in the DES. Why was it not included (the material could have been noted as "preliminary")?

In an effort to independently analyze need for the NTPC project, refiners in the northern tier states have been surveyed by mail. The following representative comments address the issue of need for the project:

> "We do not intend to support it with throughput commitments at our refinery at St. Paul and we know of no refiner who is willing to enter throughput agreements with the Northern Tier Pipeline." (Letter from John Dee Roper, Koch Refining Company, January 29, 1979)
>
> "We do not agree with an oil receiving location inside Ediz Hook. We believe that the problems of congestion, air quality control and consequences of possible oil spill are not compatible with the present development in that area." (Letter from E. A. Hall, Trans Mountain Oil Pipe Line Corporation, March 5, 1979)

CONT

> "From studies we have conducted in 1976 and 1977 and updated as recently as January, 1979, it is our belief that the primary midcontinent supply will continue to come from the Gulf Coast. A West Coast oil port and pipeline will carry only the sweet crude oil requirements of the Northern Tier States, amounting to some 100 - 150,000 barrels per day, plus the Alaskan North Slope surplus which can be utilized in refineries in Minnesota and Chicago areas. We agree completely with the DOE report which establishes the supply and demand of that ANS surplus at 300 - 350,000 barrels per day. This is why we have contended throughout that a West Coast facility to handle anything larger than 400 - 500,000 barrels per day is not only unnecessary but refuses to recognize that it could not compete with Gulf Coast supply alternatives. (Letter from E. A. Hall, Trans Mountain Oil Pipe Line Corporation, March 5, 1979)
>
> "We anticipate that the initial 1.4 million barrel per day capacity of LOOP will, in part, be utilized to supply crude oil to local Gulf Coast refineries. We would expect that the balance of the throughput would be transported through the existing Capline system replacing some of the existing transshipment operations in the Caribbean. (Letter from Larry C. Thomas, Standard Oil Company, January 31, 1979)
>
> "Sohio's studies of crude oil supply and demand in the U. S. Upper Midwest indicate the possibility of a shortfall of 50-80,000 barrels per day in the entire Ohio/Michigan area by 1985."
> "Sohio anticipates that in the future the majority of crude oil supplies for its Ohio refineries will continue to be supplied via the existing crude oil system from the Gulf Coast."
> "In addition to deliveries to Sohio's refineries, Sohio would possibly be involved either directly or indirectly in the Northern Tier or Upper Midwest states. At the present time there volumes and ultimate destinations are impossible to quantify accurately since they depend on the future West Coast market, future ANS producing levels, etc..
> "We have not made and have no current plans to make either firm or semi-firm commitments to Northern Tier Pipeline Co. to utilize their project as a supply source. (Letter from D. W. Parry, The Standard Oil Company, December 20, 1978)
>
> "Sohio's Lima Refinery cannot be supplied with crude oil from the North with existing pipeline connections even if the Northern Tier Pipeline is built." (Letter from D. W. Parry, Standard Oil Company, December 20, 1978)
>
> "We are actively trying to acquire more of these crudes and along with others, Exxon, USA supported the reversal of a segment of Platte Pipeline which will make more heavy crude available to Billings. Exxon is also actively pursuing additional volumes of newly discovered domestic light sweet crude to replace the light Canadian crudes. Some time ago we completed arrangements whereby we exchange domestic crude for light Canadian crudes to help meet our light crude requirements. North Slope crude could be used as a supplement to our heavy crude supplies but could not be used as a replacement for light Canadian crudes. We do not foresee a crude shortfall at Billings between now and 1980." (Letter from S. J. Vastola, Jr., Exxon Company, U.S.A., December 5, 1978)
>
> "As we have indicated on numerous occasions, both in public forums and in written statements and letters, Shell has no interest in the proposed NTPC system, either for Puget Sound needs of for Mid-Continent needs. We do not oppose NTPC's endeavors other then our specific opposition to a mandated hookup of our Anacortes Refinery to this system. We continue to believe that direct marine deliveries to Anacortes are safe, environmentally responsible, and attractive economically. To illustrate this point, I am attaching copies of some of our recent correspondence on this issue."
> "Our Midcontinent facilities, located at Wood River, Illinois, are adequately supplied through pipelines already servicing the area. Our Anacortes, Washington refinery receives the majority of its crude oil by tanker."
>
> "It has been suggested that Shell might wish to use the services of Northern Tier to deliver raw material from Port Angeles to Anacortes. We have publicly voiced our opposition to this play to costly to the consumer and unwarranted by environmental considerations. We continue to be opposed. Marine service is the most cost effective method of raw material supply to this refinery, and no plans exist at this time for converting an alternate method." (Letter from W. A. Melsead, Refinery Manager, Shell Oil Company, November 20, 1978)

The BLM should provide specific possible solutions as to how the Northern Tier states be supplied. For example:

1. Montana: Requires 156,200 B/D (1978)

| | |
|---|---|
| A. Produces | 89,512 B/D (1977) |
| B. Exports 71.1% of in-state production (1978) | |
| C. Wyoming supplies | 53,800 B/D (3/78) |
| D. Reversal of CONOCO pipeline | 35,000 B/D (2/79) |
| E. Canadian condensates | 60,000 B/D (1977) |
| F. Accelerated exchange program with Canada. Increased oil discoveries in Alberta enhance this possibility. In the first 2-months of 1979, the National Energy Board approved exchanges totaling 5.9 million barrels. | |
| TOTAL | 238,312 B/D |

2. Wyoming: Requires 188,600 B/D (1978)

| | |
|---|---|
| A. Produces | 306,211 B/D (1977) |
| B. Exports 60.9% of in-state production (1978) | |
| TOTAL | 306,211 B/D |

3. North Dakota: Requires 58,600 B/D (1978)

| | |
|---|---|
| A. Produces | 63,542 B/D (1977) |
| B. Exports 41.7% of in-state production (1978) | |
| C. Williams Bros. pipeline system could supply crude through reversal of the Minnesota and Portal pipelines. | |
| D. Reversal of the AMOCO product line (FEA 1976) | |
| E. The recent discoveries of potential large crude reserves in Southwestern N. D. may dramatically reduce any potential shortfalls (OGF 2/21/79) | |
| TOTAL | 63,542+B/D |

CONT

4. Minnesota: Requires 216,000 B/D (1978)

| | |
|---|---|
| A. Northern pipeline reversal from Wood River, Ill. to the Twin Cities will provide 175,000 B/D; capacity could reach | 230,000 B/D |
| B. William Bros. supplies | 120,000 B/D |
| TOTAL | 350,000 B/D |

## ARCHAEOLOGICAL/HISTORICAL

C

① Sec. 3.1.10; Page 3-35.
Deficiency: How can the cultural impacts be properly assessed if no comprehensive, detailed resource inventory has been made?

Sec. 4.10; Page 9-5.
Deficiency: The exact procedure for resource identification and preservation should be spelled out.

Sec. 1.4; Page 1-41.
Question: Since it is apparent that a relatively strict construction schedule is planned, what type of allowance is going to be made for resource recovery at the Green Point site?

Sec. 2.1.1.10; Page 2-27.
Omission: The proximity of the tank farm to the mouth of Siebert Creek would increase the possiblility that an early Indian settlement was once located there.

② Sec. 5.1.10; Page 5-7.
Question: If adequate mitigating measures are implemented, why will resources be lost? Does this mean that the mitigating measures will be construction schedule dependent?

③ Question: It is presumptious for Norhtern Tier to speak of values in an area which is of no concern to them other than in a business sense. Value speaks of a deep underlying commitment as perceived by a people who identify with an area holisitically. What local participation will be utilized to judge the value of cultural resources effected by the project?

Question: Who will survey cultural resources? What credentials are proper in this field?

Comment: Local residents should help select those persons and spot-check the survey at unannounced times to maintain objectivity.

Question: Who will insure that professionally qualified individuals are also objective in their analysis of cultural resources?

④ Deficiency: A more detailed discussion of native American traditional hunting, fishing and living areas should be included in the document. Particularly this is relevant to the Klallam Indian tribal lands which extend from Hood Canal to the Hoko River. Makah Indian tribes; lands should also be further discussed.

Deficiency: Inland locations of Indian cultural resources should be addressed further.

## EASTERN CLALLAM COUNTY

D

Comment: Many comments related to impacts of the NTPC proposal related to the west end of Clallam County are presented in other segments of this report under relevant topic areas.

① Deficiency: Some impacts of the pipeline would vary depending on the resources present in specific areas along its route; however, the risk of oil spill or leakage is of concern along the entire route. Related concerns are remedial actions in the event of a spill or leak and the extent of Northern Tier's responsibility in such an event.

Concerns center on stream crossings and potential impacts to marine and freshwater resources including groundwater. Also, concerns relate to the severe effects that an oil spill or leak could have on irrigated farm lands downstream of the pipleine. Erosion, river crossing protection, dust control, extra-heavy equipment use of county roads, lack of a source of rockless dirt in Clallam County for fill around the pipeline, lack of protection for farm animals, and quality control for the county during construction are construction-related concerns significant to Eastern Clallam County residents. Mitigating measures should be proposed to cover these concerns. A much more thorough analysis of such impact areas should be performed by the BLM.

Comment: Presently the pipeline corridor lies within a two-mile wide corridor. Particular problems which may develop within the corridor, once the exact pipeline route is designated, cannot be addressed until such time as the exact route is designated.

② The recent amendment by the NTPC, including the change to a new pipeline route in Eastern Clallam County, has been announced with less than one week remaining prior to the deadline for submittal of written comments to BLM. The DES provides a very inadequate analysis of the alternate route, and additional information has not been available from NTPC on this topic. Also, the amended plans were announced after the completion of the BLM public hearings which resulted in very little public comment on the route change.

Table 5.1.15-1; Page 5-12
Deficiency: Fire protection impacts must be further discussed by the BLM. The DES is very deficient in this area of impact. Additional training and equipment will be necessary. Fire-fighting capabilities in Clallam County are not prepared for oilport terminal, tank farm, or pipeline fire-related problems. Further discussion of fire protection, including Fire District #3 (Eastern Clallam County), is contained in the "Fire Protection" section of this report.

③ Deficiency: Inadequate analysis has been performed regarding the "Cross-Sound Pipleine" route impacts related to the public boat launch facility at Fort Williams.

④ Page 8-51
Omission: No mention of impact on Hurd Creek Fish Hatchery for the "Cross-Sound" alternative.

⑤ Page 8-54
Omission: No discussion of submarine pipeline spill impact on Sequim Bay. This area has a slow flushing action and contaminants could build up.

CONT

⑥ Also, no discussion of impact of submarine pipeline spill on the commercial oyster beds in Dungeness Bay.

⑦ Omission: A very significant impact, resulting from the route amendment, involves the probable relocation of the pipeline construction staging area formerly planned to be located at Discovery Bay in Jefferson County.

⑧ The additional commuter traffic, freighting traffic, primary and secondary work-related populations, etc., will significantly increase the impacts on Eastern Clallam County. The location of equipment storage, stock piling, coating facilities (if necessary), etc. have not been announced. Hence, no analysis is possible. This shortcoming of the DES would be another justification for a supplemental environmental statement.

## EMERGENCY SERVICES

E

① Page 2-44.
Omission: Law enforcement is only addressed as far as jail facilities and uniformed personnel. Should also discuss planned security and evacuation plans.

Page 5-23.
Omission: Table 5.2.15-1 Impact of operation does not address the problems of security, sabotage, fire evacuation, and explosion recovery.

② Page 1-16.
Deficiency: The fire fighting road system is not adequately addressed. One access road and partly on the dikes.

Page 2-44.
Deficiency: Water limitations and manpower needs are not addressed adequately. See: Coast Guard report on Long Beach ship explosion/fire, p. 14, (report 16732/71895): "Altogether the Los Angeles Fire Dept. utilized 5 fire boats, 9 rescue ambulances, 2 helicopters, 2 tankers, 2 light utility units, and various misc. equipment. Five task forces and two single engine companies were held in reserve. Five task forces and fire-fighting personnel were actively engaged in the operation." (Note: this does not include Coast Guard equipment--which other sections of the report discuss.)

③ Page 2-41.
Deficiency: Table 2.1.2.15-1. Fire protection volunteers registered with Washington State Board for Volunteer Firemen 1978 are not the same figures for those trained. In 1977-78 Fire District #3 requested more volunteers.

④ Page 2-144:
Deficiency: See above comment: This statement is not accurate for Clallam County.

Page 2-157.
Deficiency: This statement is accurate to the degree that unless more flammable products are in the harbor the increase in log and timber export would not increase the hazard risk of the harbor.

⑤ Page 3-53,54.
Deficiency: Construction phase statement is accurate. Operation phase statement does not adequately add the required fire forces needed. (See: Comment on Sect. 2-44)

⑥ Page 5-9.
Error: Table 5.1.12-2: Tanker explosion in harbor statement does not hold with all known factors of tanker explosion damage. This is a gross understatement. Fire has been shown in past tanker and storage facilities to have a greater impact.

⑦ Page 5-12.
Deficiency: Table 5.1.15-1: Referring to 2-44 comment, this is a gross understatement.

Page 5-23.
Deficiency: Table 5.2.15-1. Operations. A major explosion or fire could strain local facilities is an understatement. (See comment on 2-44)

⑧ Page 6-6.
Deficiency: Table 6.3.2-4. One explosion casualty every 4.69 years and a fire every 9.18 years in harbors. This table points up the inadequacy of the proposed addition by Northern Tier for additional fire protection.

Page 6-8.
Comment: Tabel 6.3.3-2. This table consists of statistics from the Oceanographic Commission of Washington, whose credibility is questioned elsewhere in this report. They do not take into account the increased number of tank farm fires in the last few years which has increased radically.

Comment: The Statement does not address the explosion or major fire concept adequately. No plan or method of warning is included. Section 2-44's answer to fire protection is the just major emergency problem with the lack of manpower, equipment and time, all three elements of a disaster. The second major problem would be the evacuation of areas from the lower section of the city and the areas along the bluff. Any explosion in the harbor will produce a shock wave which would have no resistance over water with the full effect along the shoreline into the central area. The Coast Guard Report, 16732/71895 notes that minor damage extends 3 to 6 miles from the explosion with the shock wave traveling overland. The 200 ft. height of the bluff would have very little deterioration power of the wave and might reinforce it due to energy uplift from the surface front. A shock wave from Ediz Hook would extend into the atmosphere as far as it would extend in all directions from the center of the explosion. Therefore a shock wave reaching the shoreline would be high enough to damage the structures on the bluff, including the Hospital, and possibly cause the chlorine at ITT-Rayonier to rupture.

Sec. 1.4. Page 6-6.
Deficiency: That we should be prepared for an explosion in the harbor every 4.69 years and a fire every 9.18 years is a bleak prospect that poses special problems since the only hospital for 46 miles around sits almost at the edge of the harbor entrance, less than 200 ft. from the water. This matter should be further discussed in the text.

⑨ Page 3-41.
Deficiency: The paragraph concerning risk of fire and explosion is unconvincing, at best. First, what is the increased risk with a third berth? Second, what percentage of explosions alone (not combined statistically with fire) result in onshore property damage in excess of $1,000. Third,

126 CONT

⑨ what percentage of inport explosions result in such property damage? Fourth, what percentage results in loss of human life? Fifth, what percentage of explosions specifically in Port Angeles harbor would result in loss of life and property damage? It is very hard to accept an unsupported statement that a Bantry Bay or California type explosion could not occur in Port Angeles, with a resulting loss of life, medical facilities, emergency air transportation (U.S. Coast Guard), etc.

Question: Use of segregated ballast tankers alleviates fire and explosion risk, but such tankers comprise less than half of the world's tanker fleet. What percentage of the NTPC fleet would be equipped with segregated ballast?

Deficiency: Accidents such as tanker explosion, pipeline rupture, storage tank rupture, and fire are dismissed as "rare" and "not expected." These events do occur and should be addressed.

⑩ Question: An emergency procedures plan for NTPC should be part of the application. How are the NTPC facilities protected from sabotage?

⑪ Question: Do any national, state or local governmental regulation control the minimum distance from a school, hospital, etc., upon which an explosive operation can be conducted?

⑫ Question: What is the increased explosive risk due to tankers without inerting systems?

Page 1-54.
Deficiency: The contingency plan and comprehensive emergency plan should be a mandatory part of the environmental statement. It could be refined later.

Page 1-55.
Deficiency: The list of Agencies telephone numbers should include Clallam County Department of Emergency Services.

⑬ P. 3-41.
Question: Based on the recent Bantry Bay, Ireland tanker explosion at an offshore unloading berth, how can such minimum damage be expected from a worst case fire or explosion in a small enclosed harbor, filled with other vessel traffic, including passenger ferry, and rimmed by residential areas? Harbor is only one mile wide at harbor entrance.

Deficiency: Does not speak to tanker explosion or fire related to worst case tanker fire or explosion with tanker in turning pattern and impacting shoreline structures, such as local mills where hundreds of men work daily.

Page 3-41.

Deficiency: Does not speak to smoke impact from tanker fires.

Deficiency: Does not speak to fire and explosions related to fuel barges.

Page 3-39.
Question: Comparing potential for explosion damage to Bantry Bay 1979 tanker explosion offshore, what is basis for statement an enclosed in-harbor explosion worst-case explosion should be limited to shoreline and adjoining land uses?

Page 3-41.
Deficiency: Explosion and fire risk statistics given for two berth installation. What would increased risks from three berth and related tanker traffic be?

Page 3-51.
Deficiency: Distances for damage fires and explosions listed as substantial for equipment, vessels and personnel within a radius of 3 to 4 thousand feet. Reference for this paragraph furnished by Mr. Booth of BLM says it is based on Vol. 5, part 1, Site Cert. parg. B.11-77. The Site Certification lists the distance from center of the harbor to Northern Border of town as 3900 feet. Center of Harbor to Northern Log Booming Area as 2400 feet. Tanker Berths to Radio Beacon at Eastern End of Spit 6,600 feet. Tanker Berth to middle of U.S. Coast Guard Base as 4,800 feet. Does not list distance from middle of Harbor to Southern shore of town. Does not speak to number of people maximum total in harbor area daily.

F

## ENERGY

① Electrical Power is one of our great concerns because of the uncertainty as to the availability of power within the next few years. Bonneville Power Administration served the City with a notice of insufficiency approximately two years ago in order that we might have plenty of time to make other arrangements to meet our needs. The City contracted with the Washington Public Power System to supply the amount we required above the amount available from BPA. This contract did not include any power for Northern Tier and there is a serious question as to whether it will be adequate to meet our needs resulting from normal growth. Some of the basic questions that remain unanswered in this area are:

a. Is there a power source other than Port Angeles from which Northern Tier can secure its electrical power?
b. In the event of a power shortage would the City Council retain the right to allocate power among the different users?
c. If Northern Tier were to secure their power through the City for the marine terminal, would this power be at the hydro-electric rate or at the thermal power rate?
d. If Northern Tier cannot obtain the necessary electrical power and must resort to diesel fueled combustion turbines, can the exhaust be treated in such a way that it will not contribute to air quality problems in Port Angeles?

② Sec. 2.1.1.13; Page 2-36.
Deficiency: Uncertainty over future availability of electrical power to supply the needs of Port Angeles City Light and Clallam County P.U.D. even without the substantial requirements of Northern Tier is cited. Discussion of the impact, both short and long term, of limited electrical power on the area is inadequate. Comparison of the job-producing potential of the pipeline per unit of energy consumed with that of other industries desirable for sound economic growth of the area is needed.

③ Sec. 2.2.2.13; Page 2-162, 163.
Error: Under "Electric Transmission" on page 2-162, it states that Table 2.2.2.13-2 shows the P.N.U.C.C. West Group Forecast of power loads and resources for March 1, 1978. Table 2.2.2.13-2 on page 2-163 shows only probability of power insufficiency for forecasted years.

CONT

④ Sec. 1.4; Page 1-10.
Deficiency: No discussion is presented on the source and type of energy which would be required in case a shipload of oil required reheating before it could be pumped through the pipeline system.

⑤ Sec. 2.1.1.13; Page 2-35.
Omission: Statement implies that a new 69 KV transmission line from the base of Ediz Hook to the unloading dock will be required. Neither a description of the line (overhead, underground or submarine) nor a discussion of its impact on the Hook's stability and use is given.

⑥ Sec. 2.1.1.13-5; Page 2-36.
Deficiency: Table 2.1.1.13-5 describes Port Angeles City Light and Clallam County P.U.D.'s present and forecasted loads but it does not state which years the forecasted load is prediciting.

⑦ Sec. 2.1.1.13; Page 2-36.
Error: The availability of thermal power from W.P.P.S.S. as described in first paragraph on page 2-36 is incorrect, since all five nuclear power projects have had rescheduling of target dates for commercial operation. The new dates for commercial operation of the five nuclear power projects are as follows:

WNP-1 - December, 1983 WNP-2 - September, 1981
WNP-3 - December, 1984 WNP-4 - June, 1985
WNP-5 - June, 1986
(Taken from WPPSS news Release No. 79-13, January 26, 1979).

Sec. 1.4; Page 1-10.
Deficiency: Statement mentions construction and use of a diesel-powered emergency electrical generator. Size of the generator and estimated frequency of operation should be given to permit evaulation of impact on air quality and noise level.

Sec. 1.4; Page 1-10.
Omission: Statement does not mention a storage tank for bunkering fuel at Ediz Hook terminal as proposed by NTPC.

Sec. 1.4.
Deficiency: Indicate size of the bunkering facility, numbers, sizes and other data pertinent to the tugs, volumes of fuel consumed by tankers and all ancillary vessels and servicing needed for these. How is the bunker fuel heated? Energy consumed?

⑧ Page 2-157.
Deficiency: The severity of the electrical energy shortage by 1982 should be emphasized considering the needs of the oilport, 20 megawatts not now available.

⑨ Page 2-36.
Deficiency: Electric energy: the final EIS should include the 1978-79 winter peak which exceeded forecasts. Residents fear that in a power crunch the local industry would be curtailed as a result of pipeline need for electricity.

⑩ Page 2-36 (con't.)
Residents also expect domestic power rates to soar as a result of need to construct expensive new generating facilities. This is a public cost and should be mitigated by asking NTPC to pay for its power on an incremental cost basis, i.e., cost of generation of new power. What price will NTPC pay for power?

Sec. 1.4.
Deficiency: Please give the power requirements for a 1.283 million bpd throughout text and on Table 1.4.14.

Error: The DES gives power requirements in terms of a 933,000 barrel-per-day capacity: a letter to the Bureau of Land Management from Butler and Associates (5/12/78) outlines power requirements for 1.283 million barrel-per-day.

Deficiency: Annual energy requirements to move 1.2 million barrel-per-day (B/D) are 2 billion kilowatt hours (KWH). This electricity load is equivalent to serving 83,333 homes for an entire year. The magnitude of such power demand should be discussed in terms understandable to laymen.

⑪ Page 2-162.
Question: Will the presence of the NTPC have a negative impact on development of coal reserves where it crosses coal fields in North Dakota and other areas? Should this problem be addressed?

⑫ Page 2-156.
Limitation on the expansion of present industries or development of new industries, because of the lack of a dependable power supply, should be discussed thoroughly.

Sec. 1.4.
Omission: Booster pumps, electric: indicate electricty consumption for 10,000 H.P. motor.

⑬ Question: Tanker engines are not very efficient, with a considerable amount of energy lost by heat. What effect will this have on water quality and marine resources? Will the above effect Washington State Class A waters designation?

⑭ Page 3-46.
Deficiency: Is growth factor and increased need for P.U.D. power included in statement basis Clallam County will have enough power if Northern Tier project not built?

⑮ Page 5-9.
Question: What is the specific "potential regional power supply shortage" with Northern Tier in the harbor? What is its actual and real impact on existing industry power requirements? If a shortage of power does occur, will the local industries be required to shut down while Northern

Page 5-9 (con't.)
Tier would continue to operate? What impact would that have on the local economy? Would new industries be restricted from locating in the area because of power shortages?

⑯ Page 5-22.
Question: What would the Northern Tier proposal impact be on the regional economy's power supply and region's ability to attract new industry to Washington and surrounding states who receive power from BPA?

Table 1.4-28; Page 1-54.
Question: Crude delivered is over 1M B/D, with a power requirement of 37,872 MWH. The power requirement is not consistent with Table 6.3.4-3, page 6-9, which contains averages of 1 mil. MWH daily.

CONT

⑰ The BLM should include a net energy balance study in the evaluation. This is particularly important in light of increasing energy supply problems. Also, since the BLM now has several alternatives before it to supply the mid-west states, energy consumption rates of the various proposals would be a proper element of comparison.

Deficiency: Please present the basis and documentation for the conclusions reached. The net energy balance should also include the energy losses due to need for mitigating measures to offset pollution and energy losses due to reduction in food chain organisms from shrimp in Port Angeles harbor to plankton at sea where ballast water will probably be discharged. Include barging of fuel to tankers, which might be a long-haul proposition if it is brought up from California rather then from the inner Puget Sound refineries. All energy expenditures related to the project should be included in the net energy study. And it would seem proper that the alternatives section of the Environmental Statement include a net energy balance comparison between all the alternatives.

G

## ENGINEERING

Comment: Overview of engineering-related material from the BLM-DES and Washington State Site Application.

This type of material is generally called "Preliminary Engineering" from the technical standpoint. It is often put together by senior personnel, technical writers or young engineers; none of whom are particularly good at detailed analysis or innovative concepts. Therefore it is not surprising that nearly all of the material is very standard stuff. There are a great many generalities and few, if any, surprises, particularly in the way of new ideas. The primary purposes appear to be to demonstrate a general knowledge of pipeline principles and to touch all possible bases.

① The basic concept of using USCGS maps as the basis for a pipeline design is probably the only practical thing to do under these circumstances, but it is hardly adequate for anything but very rough routing, pump station location and design parameters. The mathematics (pressure loss, hoop stress and horsepower) are all quite standard and adequate for this work, but they did get a little mixed up on the hydrostatic test pressure. In one place they tie it to 90% of the yield strength of the pipe, which is essentially correct, but elsewhere they relate it to 125% of the operating design pressure, which is not a truly valid criterion.

② They seem to get into the most trouble worrying about control of engine and hydrocarbon emissions. This appears to have produced at least two questionable decisions: floating roof tanks and electric pump drivers. Floaters are a very risky choice, it would be very interesting to find out if anybody else has built floating roof tanks of this diameter and in a seismic area. The alternative is vapor recovery which is, of course, very expensive and imposes difficult tank design problems.

Electric motor drivers are seldom used with pumps of this size for several reasons. First of all, they run more expensive both in investment and operation. Secondly, they run at a constant speed - making it necessary to throttle the discharge of the pump station to control throughput. This is a direct waste of head and energy. Variable speed drivers, such as internal combustion engines, permit you to achieve precise flow control by varying the speed of the machine at no cost increase.

The construction procedures are also general but seem reasonable. The labor and equipment strength (except for the pipeline spreads) seem a bit unbalanced and inconsistent, with barely enough equipment in some places and too many laborers for the number of skilled workers in others. The worst construction decision is the one to use a consultant to manage the project. Only the owners have sufficient incentive and muscle to control avaricious contractors. The latter will quickly get the upper hand, resulting in overruns,confusion, delays and loss of inspection control. The consultant really has no incentive to control the project. His fee is not based upon efficiency and his only interest is in perpetuating his contract. Alyeska and WSPPS are good recent examples of the chaos which can result from this type of a buffer arrangement.

Some committee members believe that Port Angeles harbor is just too small for this operation. While not marine experts and possibly there will not be any storm or traffic problems, they can foresee problems. The decision to locate so much big equipment on offshore platforms is certainly unusual and is probably dictated by the lack of room on the existing spit. The logical thing to do would be to fill the inside of the spit to get more room, but permits for this might be very difficult to get, so they are ducking the issue. The location of such large items as meter banks, meter provers and surge tanks which don't need to be on the wharf is an expensive way to go and greatly increases the opportunities for marine contamination. Finally on this point, a fire and explosion, when the ship was almost empty say, would be a public disaster with the downtown area only a few hundred yards away.

③ Deficiency: There is not enough attention paid to spill prevention. The major effort appears to be on containment and collection. The surge tank will not solve all the problems. For example, quick disconnects on the loading arms are potential spillers; bunkering is always messy and is bound to be more so if its control remains without strong accountability.

④ Deficiency: The pile design for the wharf is handled very sketchily. There is usally some discussion of test pile programs, batter pile design, driving formula to be used, pile lengths, etc., but here it is barely mentioned toward the end of the A.S.C. This section needs more detail.

⑤ Deficiency: The use of tank mixers is unusual, probably unnecessary and inconsistent with their assumption of pipeline quality oil from the tankers, whatever that means. This section should be clarified.

⑥ Deficiency: BLM should include a much more thorough discussion of batching. Without considerably more development in the planning and design of operations, gravity discrimination must be questioned. For example, Minas Sumatra crude has almost exactly the same gravity as Alaskan crude, but has much more wax and much less sulfur.

CONT

⑦ Question: Is it legal to have dikes around only three sides of the tank farm? The holding basin concept should be further explained.

⑧ Deficiency: Although there appears nothing really wrong with their description of the mainline pipe to be used, the discussion should be expanded. Toughness, chemical composition, cold embrittlement and other qualities could be specified or at least indicated now, but they weren't. Why wasn't a little bit stronger pipe than X65 chosen? Actually API 5X165 is sort of a minimum standard for pipe these days.

⑨ Deficiency: Welding information is also inadequate. At least the general approach to welding engineering and specification, welder qualification and control, inspection procedures and similar matters could have been discussed. What percentage of welds would be X-rayed?

⑩ Deficiency: More information is needed on engineering and construction management. Nowhere is there a mention of a cost control program or personnel to man it. Schedule control is only mentioned in passing. There is much talk about this and that work being done by "contractors expert in this field" but nothing is said about how they will be selected or on what basis, fixed fee, cost plus, target estimate or what have you. One of the most important areas in project management has been skipped over. If they are so interested in proving their technical competence with hundreds of pages of "boilerplate," why aren't they equally anxious to demonstrate their management skills as well?

Deficiency: Noise suppression data must be expanded. There is no mention of encapsulating noisy equipment and the pump stations don't even seem to have buildings around the pumps. The discharge pressure control valves at the pump stations will frequently squeal loudly. Even with electric drivers, the pumps will exceed the 70 db limit stated in their material, mainly because the requirement is so absurdly low. Alyeska never solved this problem for all equipment and is probably operating in violation of some codes today. Alaskan and other pipeline experience should be commented upon in this section.

Comment: Overview of geotechnical information utilized by the Northern Tier Pipeline Company in applications before the BLM and Washington State Energy Facility Site Evaluation

Subject Report: Geotechnical Report on Investigations and Recommendations for Terminal Facilities

The soil investigations, laboratory analyses and recommendations were performed and reported by Shannon and Wilson (consultant) of Seattle for Swan and Wooster (engineer) of Seattle, the latter firm presumed to have been retained by Northern Tier to perform the detail engineering for the terminal facilities. In general, the report is considered to provide adequate coverage of the foundation media and recommendations required to proceed with final design. However, additional exploratory borings and soils work will be required during the engineering phase to more precisely define the soil properties in areas of final locations of structures, submarine pipelines and final design concepts should these vary from present thinking.

The investigations covered in the report consist of exploratory borings made in the proposed areas to be occupied by the fixed dock structures, the submarine pipeline and the tank farm at Green Point including pump station and other auxiliary structures and earthwork. Representative samples were taken from the borings, with N values being determined by standard penetration procedures as a measure of the density of the soils encountered and their resistance to pile penetration. Water content of the soils was determined and logged in depth. A number of grain size determinations from various borings at varying depths were also made, plotted and presented in the report. Samples from the dock area were analyzed to determine the resistance of the soils to lateral pile loads. The results of these investigations and recommendations, together with comments, are covered below for each of the three main areas of construction covered by the report.

In general, all soils encountered in the borings are noncohesive and granular in nature consisting of fine sands to gravel of moderate size. These soils extend in depth below pile tip elevations, no bedrock having been encountered in any of the borings. From Ediz Hook to a point about 1/3 the distance to Green Point, the soils near the surface are of recent origin and relatively loose as compared to the underlying material which are described as glacially overriden soils of greater age. These underlying soils are classed as dense and are exposed at the botton for some half the distance to Green Point as well as comprising practically all soils within the Green Point area.

### Dock Area

The looser surficial soils in the dock area vary in depth from shallow up to about 20 feet and will offer relatively little in the way of resistance to pile loading or to driving resistance. The consultant studied three sizes of open end pipe pile presumably being considered by the engineer for the various dock structures. The largest of 36 inch diameter is considered for those structures subject to heaviest loading, the separated breasting and mooring dolphins. The smaller sizes, 24 inch and 18 inch, are considered for the platform and walkway structures respectively. The design concept, apparently, for the heavy structures is to arrange the 36 inch piles in vertical and/or batter configuration and tied together at their tops with massive concrete caps, to resist vertical loads and those lateral loads incidental to berthing and mooring. A maximum design load of 500 tons was used in the report for the study of these piles. This is a credible loading considering the design concept and the recommendation of the consultant that, due to driving difficulties, a small batter of two in twelve should be considered.

The consultant analyzed, by means of the Wave Equation Theory, the required depth of penetration for all pile sizes to achieve the stated safe loadings. According to this, the 500 ton pile must be driven in the order of 50 feet into the dense soils underlying the looser material. To accomplish this, they recommend the use of a 300,000 foot pound hammer. This size hammer has not been around long and was undoubtedly developed for driving the anchor piles in offshore drilling platforms. A lighter hammer rated at 100,000 foot pounds is recommended for driving the smaller piles.

126
CONT

A ground acceleration of 20% gravity is recommended for design of the dock structures for resistance to earthquake forces. This was based on a Modified Mercali intensity of VII which can be considered amply conservative for this area. Ground motion associated with an earthquake of this intensity could, conceivably, cause liquefaction of the loose surface soils in the area. Such an occurence would pose no threat to the dock structures; however, to prevent damage to the submarine pipeline, it is recommended to be laid at a depth in close proximity to the top of underlying dense soils in the vicinity of the Hook.

In considering the type of design and construction of facilities at the Hook, as implied by the report, only two adverse influences are seen, namely:

1. The use of a 300,000 foot pound hammer and the lighter one is bound to prove offensively noisesome to residents of the community over the period of time required to penetrate the dense strata and complete the driving work. Although jetting was specifically not recommended in the report, there are ways of mitigating the noise problem, e.g., preboring or controlled jetting inside the piles or, conceivably, an entirely different design approach. Either of these alternatives should, in the interest of cost savings alone, be studied by the engineer prior to establishing a firm and final design.

2. Considering the heavy floating equipment and construction activity in the dock areas, it would not seem possible for the public small boat launching ramp to remain useable at its present location during the construction phase. There is no valid reason why the public should be deprived of this facility and NTPC should come up with a statement on this matter.

Submarine Pipeline(s)

A number of borings were made along the proposed route of the pipelines from the docks to Green Point indicating that for most of the route the lines will require burying in the dense, glacially overridden soils. No recommendation is made as to what this depth should be except in the shoreline surf area at Green Point where they recommend rock backfill in the trench over the pipe and shoreline rip rap protection. Conservative side slopes are recommended for the cut in the Green Point bluff together with the means by which the cut should be backfilled and finished off after installation of the lines.

The only significant departure in the report from the NTPC statement is the latter's proposed means of excavating the submarine trench by jetting. For most of the route this does not appear feasible and, as the report points out, the dense bottom soils will require excavating by clamshell.

Tank Farm

The report confirms that all of Green Point is composed of dense granular soils in depth and provides excellent foundation media for the storage tanks and other facilities. Loads imposed by the 54 foot high tanks can be carried by the soils with a high factor of safety. Tank settlements of a few inches are predicted and, due to the granular nature of the soils, would occur as loading is applied. There is sufficient fine material in the soils to create wet weather handling problems especially in construction of the tank pads which are recommended to be compacted to 95% relative density. Concrete tank ring walls are envisaged for all of the oil storage tanks. Conservative recommendations are made for compaction and side slopes of the tank retaining dykes. Planting is recommended for cut or manufactured slopes as protection against erosion. Design soil bearing values are given for auxiliary structures. e.g., the pump station.

Summary and Conclusions

The geotechnical report is, for design and construction purposes, fairly comprehensive and definitive, although some additional exploratory and engineering work will undoubtedly be required in specific areas if final design proceeds. The recommendations made are, in general, conservative. Soils in all areas are non-cohesive and considered to provide an excellent foundation media, although for the dock structures, their potential at this point in time do not appear to have been fully considered by the engineer.

Emergency Generator
Deficiency: Emergency generator location easily accesible to berth operation.

Deficiency: Should also have capability for starting manually if auto fails.

Deficiency: Also located where best protected from adverse weather conditons or mechanical damage.

Question: If emergency generation fails to take-over on power failure, what happens?

Question: What time delay can be expected for take-over of emergency generators?

Controls and Berthing; Page 1-9.
Deficiency: Tanker berthing dock operator should be able to stop booster pumps immediately. Not wait for control system to be activated from on shore storage facilities. Emergency stop controls should be located at all service platforms and pump platforms.

Storage Support Facility; Page 1-15.
Mitigation: Considering the concern expressed in the statement for visual impact on the environment, it should be established that this tank will be aesthetically pleasing, as elevated tanks go, e.g.,spherical or torospherical type.

Onshore Storage Construction; Page 1-41.
Mitigation: Paragraph six on this page covers hydrostatic testing of tanks. In consideration of possible adverse impacts on local water supplies, test water should be reused for as many tanks as feasible.

Tanker Unloading Facility; Page 1-7.
Deficiency: The description of the fixed berthing and mooring structures should contain, at the least, a brief statement covering the design basis for these structures. To cover this elsewhere in the statement by reference to governing codes of practice, regulatory provisions, etc., ie, in the absence of any codes or regulations governing marine

CONT

structures of this type, insufficient for these critical structures. Without getting into "highly technical" discussion, the statement should have established that these structures will be designed and constructed to resist safely certain spelled out forces in accordance with the most current state-of-the-art.

⑪ Onshore Storage Facility; Page 1-14.
Question: Fifth paragraph on page 1-14 states that spillage of oil from storage tanks would be controlled by low dikes surrounding groups of tanks and remote holding or impounding basins. Is it standard procedure in the industry to provide only one dike for eleven tanks of the proposed size? If one tank in this group is ruptured and a fire ensues, or vice versa, what is the vulnerability of adjacent tanks with due regard for the fire protection system proposed?

General Comment
Omission: The criteria and the document indirectly mention safeguards due to failure of any of the operations or systems.

Omission: The main thrust is environmental impact without explaining or requiring specific statements on the effect of failure of the communication and control system.

Omission: The data presented is voluminous but there is not summary for safety (protection of people and the environment).

Omission: It is unclear how a feasibility determination could be made from the data presented with respect to fail-safe operation.

Purpose of Proposed Action; Page 1 thru 63.
Deficiency: Insufficient detail to assess the reliability or impact of communication system failure including controls.

Environment and Product; Page 6-10.
Deficiency: No mention made of effect on fishing, log booms bottom disturbance from tanker propellers, access to boat launching ramp, etc.

⑫ Pipeline Supply Map; Fig. 1.
Deficiency: Map does not show all pipelines in place that could serve area.

⑬ Sec. 1.4; Page 1-50.
Deficiency: The ES states "terminating operations would lead toward abandonment and possible disposal of all or portions of the entire system." The word "possible" in that statement is too vague. If operations are terminated the system should be disposed of as directed by some appropriate authority. Additional information is required to permit the general public to know what will happen if and when operations are terminated.

⑭ Page 3-37.
Deficiency: Does not address economic and hazard impacts relating to leaving submarine pipelines hanging on Green Point Cliff. "If" is not a procedure description.

⑮ Page 3-39.
Deficiency: Impacts from unspecified abandonment responsibility would result in greater than nuisance impacts for city and county. BLM should address this probability.

Deficiency: Please discuss whether any financial arrangements such as a bond are contemplated to assure that costs of proper final disposal can be met without public burden. It seems that if there is insufficient crude oil or other economic difficulties the pipeline might well go bankrupt and unable to take care of that disposal properly.

⑯ Page 3-55.
Deficiency: Specific abandonment procedures and responsibilities of applicant not spoken to.

⑰ Page 3-14.
Deficiency: What preventative measure during abandonment would be taken to prevent sedimentation in Seibert's Creek?

Page 1-14.
Deficiency: Paragraph 11, 2nd sentence states: "The filtering and coalescing stage may be bypassed when no oil is present." It is believed the bypass capability should be eliminated, one more chance of human error would be removed.

⑱ Page 1-29.
Question: Figure 1.4-4: Should heliport be relocated to an area between strainers, the control building and fence? Having the heliport in a corner creates the risk of the helicopter rotor contacting the fence and possibly causing the aircraft to crash. It is not uncommon for aircraft crashes to result in fire. Having the heliport in a more open area will reduce the possibility of a crash.

⑲ Question: Figure 1.4-4: Some objects in the drawing are unidentified and some are obvious. Two things near the fence between the surge tank dike and the remainder of the pump station have the same physical characteristics as the valves, but they are not identified. What are they?

⑳ Page 1-30.
Question: Figure 1.4-5: Should heliport be relocated to a more open area between the strainers, control building and fence? (See item 1.4-4 above for rationale.)

㉑ Question: Figure 2.4-5: Two objects near the fence about in line with the manifold system between the surge tank dike and the rest of the pressure reducing station are not identified. What are they?

㉒ Page 1-33, 1-34, 1-36.
Question: Figure 1.4-6, 1.4-7, 1.4-8: It appears that the dike has openings on two sides. Is there an opening on two sides or is the figure drawn that way because it cannot be done to scale and get it on the page?

㉓ Page 1-50.
Question: Paragraph 7: What would be the qualifications of the individual making the certification?

㉔ Question: Paragraph 8 states in part: "All oil in the piping and valves within the tank farm would be drained and transported to another operating system in the area." There are no other systems in the area. Where would it be taken or how would disposal be accomplished?

㉕ Question: Paragraph 8 last sentence: Since oil and water are immiscible, how free of residual oil will the system be?

CONT

㉖ Question: Paragraph 9: What qualifications will the person doing the certification have?

㉗ Question: Paragraph 10: What would the inhibitor be? Might it be hazardous or cause environmental degradation?

㉘ Sec. 1.4.
Deficiency: What is the magnitude of induced voltage that could exist in a multiple use pipeline corridor? What are the effects, if any, on the pipe wall, on soil organisms, on burrowing animals, on plants and on wildlife from such currents? Is the build up sufficient to cause a shock to man or animals? To have a heating effect? To interefere with radio or television reception? What are the effects of the cathodic system to plants, soil organisms, burrowing animals, wildlife and man from the cathodic pipe protection system?

㉙ Deficiency: Pipeline system: Note ultimate capacity of 1.283 million bpd. What width of pipeline right-of-way? Which side of BPA right-of-way across Clallam County?

㉚ Deficiency: Pipeline: What stresses in pound/square inch are present in the normally operating filled pipeline at the peak impulse of pumping at the bottom of the longest decline in the entire system (1500+ miles)? What will the stresses be at maximum from temperature effects of extreme weather? From ground settlement? From seismic shifts? What kind of pressures are encountered from avalanches in mountain passes? From landslides?

㉛ Sec. 1.4 (con't.)
Deficiency: Describe rusting and corrosion of the grade of steel to be used in terms of corrosiveness of soils to be traversed and in terms of corrosiveness of types of oil to be carried, interpreting these so one can tell about how long it will be before the first corrosion leak occurs, and so that it is possible to know how long the pipe can carry the stresses mentioned previously.

㉜ Deficiency: Will welds be X-rayed? How are records kept and how are they monitored? Will there be publicly available results of such testing?

㉝ Deficiency: Why is not double walled piping required for all river and stream crossings with an alarm system to detect breach of the outer pipe wall? How is pipe protected when it cannot be buried below the scour depth of a stream or river? Which streams and rivers are affected by this condition? Where are the references and background data for scour depths of all rivers and streams to be crossed? This should be included in a Technical Addendum. When a stream is not named, as Eagle Creek or Jorstad Creek, in your list of streams and river crossings, does that imply no special pipe will be used in those places? If so, the EIS should include the downstream outflow points of such streams as areas especially at risk and point these up under environmental costs with a relatively high cost factor.

㉞ Deficiency: Major estuaries are fed by such streams and many of the river crossed and are tremendously valuable for food production. There is no substitute area on the Pacific Coast for Dabob Bay to raise oyster seed. Should it become oil-fouled, the economic and environmental damages would be very high. Economic impact assessments should be made of areas such as this (e.g., Sequim Bay, Dungeness Bay, Discovery Bay, etc.).

㉟ Deficiency: Describe the standards for hydrostatic testing of pipes and relate this to amount of oil leakage that would be tolerated under these standards. What is the operating reliability of the electronic controls (historic data)? What is the historic operating reliability of human performance at control stations and tank farms? What proportion of spills have been due to the human factor?

㊱ Deficiency: The quality of pipe metal used should contain a description of its ability to withstand oxidation in fresh and saltwater environments and its resistance to corrosion from within. What is the expected time before the smallest leak can be expected? When can we expect significant deterioration in the various environments and what is the half-life of such pipeline in these environments? (Presumably the weakest link would determine this.) Does cathodic protection work in the vicinity of other installations which are grounded or which carry electricity?

㊲ Sec. 1.4 (con't.)
Deficiency: This pipeline will, in places, be crossing marshy ground. What special provisions are planned to reduce settlement and resulting strain on the pipe walls and what is the design criteria for amount of settlement in the soft spots and permissible pipe deformity between hard and soft spots?

㊳ Page 140.
Deficiency: Explain how welds can be inspected and tested for the lay-barge method of construction and any imperfections corrected in timely (before pipe is oil filled) fashion. What provision is made for oversight of crews? Can pipe be retrieved if it has a faulty weld and is laid underwater?

㊴ Sec. 1.4.
Deficiency: In pressure testing segments of pipe with water, what measurements are made, with what instrumentation and what criteria are applied? Is any pressure drop over a 24 hour period acceptable? Is this test made before or after pipe is covered with dirt in the trench? If done after, how can a leak be found and fixed?

Omission: What is the reliability of densitometers? Discuss the probability that oil from a common source might occur in successive batches and the probability rate for a situation in which the control center is not alerted to dispatch oil from a tanker.

㊵ Question: What size seismic event would be tolerated by these 285 ft. X 56 ft. high tanks? By the juncture of the subterranean pipes with fixed facilities at the berths and on land? Along both subterranean pipes and on land pipes? What is the historic record for seismic failures in those various categories?

㊶ Omission: Construction schedule: How is this to be modified by changing plans of NTPC? With major revisions in plans as for an underwater crossing of Puget Sound, large parts of the EIS will have to be revised. Table 1.4.17 would need complete revision for Washington State.

CONT

㊷ Page 3-50.
Deficiency: Does not define specific scope of Phase II construction at onshore storage. Maximum number of tanks to be added whether or not third berth installation accompanies same.

㊸ Page 1-8.
Deficiency: Three submarine pipelines and three berths should be acknowledged and evaluated as a reasonable, foreseeable part of the NTPC proposal.

㊹ Deficiency: The need to give background data supporting scour depth of streams has been mentioned.

Sec. 2.1.2.6-2.
Deficiency: Characteristics of major river crossings 2.1.2.6-2: Please give references to source material. Where can we see the description of how these values were obtained and assess the adequacy of the underlying studies? The only source quoted is NTPC.

㊺ Sec. 1.4.
Deficiency: In erosion control, what criteria will be used to determine whether ditch lining and ditch checks are necessary? In laying the line, describe the process for going through rock and give the relationship of blasting areas to distance to residences.

㊻ Deficiency: The BLM-Des implies that mechanical failure safety hazards are to be considered negligible because of both the isolation of project components and the design measures incorporated into the system. Mechanical failure impacts are not adequately discussed.

㊼ Question: ,What is the historic record of human failure with regard to pipeline storage facility malfunctions?

㊽ Question: Is the spacing of the storage tanks at the proposed tank farm adequate for safety? Reportedly, the Elk Hills Reserve has spaced tanks at 1-1/2 diameter, considerably more than NTPC.

H

FIRE PROTECTION

Note: Several comments related to the issue of Fire Protection are discussed in the "Emergency Services" section of this report, and briefly in the "Medical" and "Oil Spill" sections.

Comment: Fire Protection is an area that worried many citizens of Port Angeles and Clallam County primarily because of the large tankers that are being considered for use in Port Angeles. Because of the great hazard involved, fire protection requires much more extensive treatment than is given in the D.E.S. No attention is given to a ship that might catch fire while waiting to unload or what might happen if a burning ship floated away from the dock where the fire-fighting equipment is located. Specialized equipment stationed in Seattle would be of little or no value since steaming time from Seattle would be at least five to seven hours away. NTPC statements and the BLM-DES have yet to provide for adequate fire protection equipment. In the event the pipeline is constructed and eventually expands to three berths, then the possibility of manning additional fireboats and other additional facilities should also be considered.

In the long run the continued growth in the eastern and western portions of Port Angeles will surpass the ability of a single fire station with fifteen paid personnel and twenty-four volunteers to furnish adequate fire protection to Port Angeles. However, if Port Angeles is subjected to an influx of 500 to 1,000 construction workers, then it will simply overwhelm our fire protection capabilities. Within the past few years the City has been gradually upgrading the equipment, but in no way would they be capable of absorbing this type of growth within their present configuration. The geography of Port Angeles also contributes significantly to the ability of the department to offer fire protection to the community. Port Angeles is laid out in an East-West direction and is bisected by four canyons or ravines which create difficulties in going from one part of the community to another.

① Deficiency: The tank farm area is of great importance to proposed fire protection. It has many areas to be dealt with, but with the information provided, comments cannot be made. Local fire protection officials need more details before meaningful analysis can be conducted.

Deficiency and Omission: Fire protection is mentioned only in a general way in a very few short paragraphs. No assessment of impacts by fire or explosion are discussed at all. A few sentence superficial review of some of the fire protection facilities to be provided by NTPC is given but there is not enough information given to even attempt to assess the magnitude of the problem or the adequacy of the fire protection that may be provided.

Due to the limited fire fighting capabilities available in our area only tankers with segregated ballast and tank inert gas systems should be allowed in our port. A statement to this effect should be contained in all proposals relating to an oil port in Port Angeles.

Page 1-8; 1-10.
Deficiency, Omission and Error: Location shown on drawings of the diesel driven fire pumps near the booster pump platform is unsatisfactory as it is too exposed to damage in case of fire or explosion. Pumps should be located ashore in pits or other protected locations as close to water level as possible. Two separate pump locations are necessary with separate suctions, controls and valves so either pump may operate independently of the other. Suction inlets and their maintenance in salt water present a special problem and must be carefully designed. Necessary pump capacity has not been discussed or detailed disruptions or locations of hydrants, fire mains, fire fighting, chemical storage and locations and number of necessary fire appliances given.

Page 1-10.
Deficiency and Omission: Tugs and line handling launches supplied by private service companies should be required to have auxiliary fire pumps and monitors with foam capability at capacities to be designated by the Port Angeles Fire Department.

The fully equipped fire boats should be moored at a secure location away from the unloading pier yet readily available. The size, pumping capacity, foam capacity, manning level and other equipment is not specified but it should be as specified by the Port Angeles Fire Department or its consultants.

126 CONT

Page 1-15.
Comment: Due to the distance these storage facilities are from the City of Port Angeles it is doubtful the Port Angeles Fire Department would take part in developing firefighting procedures or detailed design as stated in the BLM document.

The Clallam County Fire Marshal and Building Department along with the appropriate Rural Fire Protection Districts would have responsiblity in this area. These local government officals have not been provided with enough details regarding fire protection plans to make a meaningful analysis.

② Page 2-44.
Error: The statement that the Port Angeles Fire Department has four standard pumper trucks and a pumper-ladder truck is in error.

In fact we have two standard pumper trucks and a pumper ladder truck in service with one 25-year old pumper truck with limited equipment in reserve.

③ Page 1-16.
Deficiency: The fire fighting road system is not adequately addressed. One access road and partly on the dikes.

Page 2-44.
Deficiency: Water limitations and manpower needs are not addressed adequately. See: Coast Guard report on Long Beach explosion/fire, P.14. (Report 16732/71895): "Altogether the Los Angeles Fire Dept. utilized 10 task forces, seven single engine companies, 5 foam apparatus, 5 fire boats, 9 rescue ambulances, 2 helicopters, 2 tankers, 2 light utility units, and various misc. equipment. Five task forces and two single engine companies were held in reserve. Some 240 uniformed fire-fighting personnel were actively engaged in the operation." (Note: This does not include Coast Guard equipment—which other sections of the Report discuss).

④ Deficiency: The DES does not address the explosion or major fire concept adequately. No plan or method of warning is included. Section 2-44 is concerned with the fact that in-fire protection is the just major emergency problem with the lack of manpower, equipment and time, all three being potential elements for a disaster. The second major problem would be the evacuation of areas from the lower section of the city and the areas along the bluff. Any explosion in the harbor will produce a shock wave which would have no resistance over water with the full effect along the shoreline into the central area. The Coast Guard Report, 16732/71895 notes that minor damage extends 3 to 6 miles from the explosion with the shock wave traveling overland. The 200 ft. height of the bluff would have very little deterioration power of the wave and might reinforce it due to energy uplift from the surface front. A shock wave from Ediz Hook would extend into the atmosphere as far as it would extend in all directions from the center of the explosion. Therefore a shock wave reaching the shoreline would be high enough to damage the structures on the bluff including the Olympic Memorial Hospital and possibly cause the chlorine at ITT-Rayonier to rupture.

⑤ Sec. 1.4.
Omission: What size fire can be handled by the equipment described? What would be the likely extent of the damages for a fire outside the ability of local equipment to control it, considering the long steaming time for equipment coming here from the Seattle area? What will happen to fire insurance rates for industries sharing the harbor? For residences in the vicinity? Has proponent committed to paying the increased premiums?

Sec. 1.4.
Deficiency: What is the volume held by the water tank? What is the distance between and water voulume capability of hydrants? What is the placement interval and capacity for foam chambers on top of tanks? How effective have these proved in actual use? How many portable dry chemical units and what size? Any insulated fire-fighting suits available? How many? How large a fire truck with what capabilities? How well trained a crew? Are foam trailers provided? If so, how many and what capacity? Describe the manpower available and equipment available from off-site firefighting sources: (a) within 30 minutes, (b) within 1 hour, and (c) within 2 hours of an emergency call.

⑥ Paragraph 1; Table 5.1.15-1; Page 5-12.
Deficiency, Omission and Question: Where would the timely receipt of assistance arrive from in case of a major fire? Trained or volunteers? The comments relative to local firemen and fire districts in this draft are very rudimentary and give very little insight into their ability to cope with major impacts of this nature.

⑦ Paragraph 4; Page 3-54.
Deficiency: Fire, Protection data currently unavailable. Why?

Deficiency: What is the basis for assumption one fireboat for the harbor and one fire truck for onshore storage with 25 tanks would be adequate protection? Information needed for operation phase related to water supply, water storage, insurance rates, and trained personnel. Location of all equipment.

Deficiency: Does not speak to increased firefighting risks associated with third berth installation.

Deficiency: Does not discuss traffic congestion and emergency evacuation procedures related to total harbor area related to hundreds of workers in area daily and inadequate street and road access to Ediz Hook area?

Deficiency: What protection would be provided for city and county residents from fire during abandonment?

Deficiency: Does not discuss fire safety and firefighting equipment requirements and personnel relating to Northern Tier project responsibilites. Does not discuss economic impact on community taxpayers.

Deficiency: How would necessary quantities of water for firefighting be provided and at whose expense? How much water would be required to fight a catastrophic fire and/or explosion?

Deficiency: Does not discuss current water line to Ediz Hook in terms of water available and current water total usage by existing harbor users.

Deficiency: Does not discuss method, equipment or water supply for onshore storage firefighting. What is water source? How much water would be required? How much would be stored? How would additional water beyond storage capacity be obtained, from what source and at what pumping rate?

CONT

⑦ Deficiency: What effect would NorthernTier project have on insurance rates for residents and businesses in onshore and harbor areas?

⑧ Comment: Are local tug boat crews and equipment available and authorized by their owners for firefighting in the event of major catatrosphic fire or explosion. Are the crews insured and trained for this specific duty not related to their work scope. Basis for assumption that Coast Guard is available and responsible for fire fighting.

⑨ Page 1-10.
Comment: Would Northern Tier provide manpower for the Fire Boat or would local fire services be expected to provide trained personnel?

Page 1-15.
Comment: Provisions should be made to keep the capacity of one tank available in one or more tanks at the on shore facility. If a tank were to become involved in a fire the crude could be pumped into the ullage reducing the amount of crude involved and would reduce the chance of oil froth being generated. Oil froth could be more disastrous than a fire.

Page 1-14.
Comment: A fire protection system status display panel should be provided.

Page 1-15.
Comment: Regarding the utility fire truck, who would be responsible for housing, manning and maintaining the vehicle, the Fire District or Northern Tier?

Page 1-15.
Comment: Paragraph 8 states: "Firefighting procedures and the detailed design of the fire protection system would be developed in cooperation with the Port Angeles Fire Department....." The onshore facility is to be located in Clallam County Fire Protection District #3, not Port Angeles. Firefighting operations are the responsibilty of District #3. Fire prevention is the responsibility of the Clallam County Fire Marshall. A statement should be added to read essentially: Fire protection and fire fighting procedures will be developed in cooperation with the Clallam County Fire Marshall and the Commissioners of Fire Protection District #3 through the District Chief and the Port Angeles Fire Chief. The County Department of Emergency Services will be consulted to insure contingency plans are developed.

Page 1-54.
Comment: Clallam County Department of Emergency Services and Clallam County Fire Protection District #3 should be included in the development of contingency plans for Clallam County facilities.

Page 1-56.
Comment: The manning of the fire boat is discussed previously. Will NTPC provide manpower for the fire truck or will Clallam County Fire Protection District #3?

Page 2-44.
Comment: As it relates to Fire Protection District #3 should read: Fire Protection District #3 which serves the Green Point area encompasses over 164 square miles. It has a full time paid chief and 80 volunteers. There are five fire stations, 6 pumpers, 3 water tankers, 2 aid cars and a chief's vehicle. It is rated 8 by the Washington Surveying and Rating Bureau. (The scale used is 1 to 10 with 10 being the lowest level of protection.)

Page 2-44.
Error: Paragraph 3 is not accurate. Sequim has one pumper, one pumper belongs to Fire Protection District #3 and is housed in the Sequim Fire Department. It is used by the Sequim Department to respond to fires in Sequim and in part of Fire Protection District #3 immediately around Sequim.

Page 5-12; Table 5.1.15-1.
Comment: Unavoidable impacts. Fire protection during operations. In addition to straining local departments, residents in the Green Point area would be greatly inconvienced by fire fighting activitiess, spectators, news media and from the smoke and possibly oil froth. Residents with shore property that permits a view of the Green Point area would undoubtably be bothered by the press and television news people seeking spectacular photo coverage of any major fire or explosion.

## FISHERIES

I

① Sec. 3.1.7; Page 3-32.
Omission: Fish - statement is assumptive, vague, and in error. Salmon are most vulnerable to oil on the water when emerging from spawning areas or during their early life stages in shallow inshore waters. Because they live and feed in the upper (<30 feet) layers of oceanic/marine waters, adult salmon could be adversely affected by the oil (SOHIO; 3-386).

② Sec. 3.1.7; Page 3-32.
Deficiency: Fish - statement does not detail the effects a spill would have on a river system which has a deltaic salt marsh zone. The Dungeness River is an example. Salt marshes are highly vulnerable to a physical impact from a spill (Table 3.1.7-7) and would be adversely affected.

③ Sec. 3.1.7; Page 3-28.
Deficiency: Community impacts - "Effects vary so much that it is difficult, if not almost impossible, to give a general discussion of such impacts . . ." SOHIO Impact Statement quantified the same type of information into our economic analysis for fisheries impacts. This statement (BLM) should provide same.

④ Sec. 3.1.7; Page 3-32.
Error: "Oil-spill effects on ocean dwelling eggs and larvae would be relatively minor." The eggs and larvae have no mobility and could not avoid a spill. They would be severely impacted, particularly if they are within 30 feet of the surface. The ultimate effect would be suffocation or lethal toxicity.

Sec. 3.2.6; Page 3-72.
Question: Biological components/Summary (2nd paragraph) If the spawning runs are reduced for several cycles, what is the time span? A spawning cycle (life cycle) for many salmonids is 3-5 years. Several cycles, as stated in text, could imply 15-20 years. This is significant.

CONT

⑤ Sec. 3.2.6; Page 3-72.
Question: Biological components (4th paragraph) What would be the effect of a spill on a river system in relation to ambient temperature variations. Oil, being somewhat of a black body, would be expected to exert an increased temperature. Statement should acknowledge and clarify.

⑥ Sec. 3.1.15; Page 3-50.
Deficiency: Operation phase (4th paragraph) "Some cleanup costs would be incurred . . ." Real dollar values have more meaning! Quantification is desired: loss to fishery, to gear, and to boats.

Sec. 3.1.15; Page 3-50.
Question: Operation phase (4th paragraph) If salmon and "other fish" avoid a spill, how could their flesh be tainted? Is "avoidance" an assumed condition?

⑦ Sec. 5.1.7; Page 5-6.
Question: "A chance encounter by phytoplankton and zooplankton . . ." What exactly is a "chance" encounter? No degree of probability is offered.

⑧ Sec. 5.2.6; Page 5-16.
Deficiency: Twenty years for recovery of salmon populations effectively kills a fishery for that system. How does this translate into an economic loss to the fishery? Specifics for the primary systems should be required.

⑨ Sec. 5.1.6; Page 5-5.
Question: Is there the possibility of oil run-off into Seibert Creek during a heavy rain storm (50 year storm intensity)?

⑩ Sec. 5.1.7; Page 5-5.
Question: Paragraph states that "strategic booming" off of Green Point could contain a spill and implies that conditions in the harbor are equitable with conditions off of Green Point. This is misleading. Green Point is subject to intensive oceanographic conditions while the protected harbor is not. Is booming an effective oil containment method for an area which regularly is subject to large waves and swells.

Sec. 3.2.6; Page 3-78.
Deficiency: Oil spill in a river system could effect a significant impact on a year-class of salmon. This would ultimately be realized by the ocean sport, commercial, and Indian fishery. Timing of spill also would be an important factor.

⑪ Sec. 4.6; Page 4-3.
Question: Would diversion of the river increase flow velocities, increase suspended sediment and turbidity? Could this also effect the biological systems and impose additional stresses? Would it alter the flow patterns of the river to such a degree that additional flood hazards would be evidenced?

⑫ Sec. 2.1.1.7; Page 2-22.
Deficiency: Paragraph 1 states that "some commercial and sport fishery are found in the west strait, but not to the extent found in the east strait." This statement is contradictory. The majority of the sports fishing resorts are west of the Lyre River and one of the most significant Indian fisheries (Makah) is located in the west Strait. The importance of the Strait fisheries should be presented as an aggregate and not as a segregated unit.

⑬ Sec. 3.1.6; Page 3-26
Deficiency: Destruction of eel-grass beds. According to the text, the eel-grass beds within Port Angeles harbor may reestablish "by the next growing season." The construction phase, however may overlap from one season to the other. Additionally, the next growing season implies that the biological community dependent upon the eel-grass beds would begin reestablishment within a year. This is erroneous. The biological community would experience an oscillatory phase of recovery over several years. If additional stresses are imposed (i.e. oil spillage), the community could be erradicated.

⑭ Sec. 3.1.6; Page 3-14.
Omission: Construction phase (1st paragraph, last sentence) If "overland flow" reaches Seibert Creek, what impact would it have on the biological communities in this aquatic system?

⑮ Sec. 3.1.7; Page 3-15.
Omission: Summary - entire section. Translate impacts from estimated spill frequency on marine resources into an economic evaluation (e.g. economic losses). Such should be within the framework of data presented in the SOHIO Impact Statement for the Long Beach Terminal proposal.

⑯ Sec. 3.1.7; Page 3-26.
Deficiency: Construction phase (1st paragraph). Tidal organisms may establish new communities, provided that low level oil spillage from operations would not stress these organisms. No information is provided in this respect.

⑰ Sec. 3.1.7; Page 3-26.
Omission: Operational phase - No economic analysis is provided for fisheries impacts. This information should be provided.

⑱ Sec. 3.2.6; Page 3-75.
Deficiency: Biological components - construction phase (6th paragraph). The Dungeness River's high sediment load is attributable to its source region characteristics. Increased sediment values over its natural ambient levels could possibly stress indigenous fish species within the river system.

⑲ Sec. 3.2.6; Page 3-75.
Error: Biological components - construction phase (paragraph 11). The Dungeness is a cold water system. Statement in paragraph 11 states that cold water fishes would be impacted by higher sediment loads than warm water fish. This contradicts the statement in paragraph 6, about the Dungeness River, etc.

⑳ Sec. 1.2; Page 1-1.
Question: What are the potential explorations and exploitations for and of oil and associated resources, and the likelyhood of that activity, in the region from the central Washington coast to central Vancouver Island ocean coast, seaward and landward, that would be encouraged by increased economic attractiveness and convenience of the Port Angeles oilport proposal acceptance?

㉑ Table 1.4-9; Page 1-56 (para. 7).
Omission: Project would cross Dungeness irrigation project.
Mitigation: Major river crossings might include sealed casing. Effectiveness - provide secondary protection against water network contamination. Require critical (as defined by concerned local agencies) waterway crossing pl ssing be heard individually and specifically in detail by appropriate agency(s) prior to issuance of overall proposal approval. Effectiveness-insures acceptibility of planning on case by case base, on each cases merit, negating problem solving(?) in the biased atmosphere of overall project approval "and consequent loss of status for concerned arguments (environmental sensitivity)."

CONT

Sec. 1.4; Page 1-56.
Question: As construction may be required to recognize temporal environmental sensitivity, is it possible to preplan potentially necessary repair work in recognition of constraint continuity? Can we devise a hypothetical situation for discussion? Are there any alternatives between a 10 month shutdown of the line and maximum environemntal impact?

㉒ Sec. 1.4; Page 1-58 (#25).
Question: Does this mean we will have help to increase tax revenue demand (by extension: increase taxes) to cover the troubles we don't want anyway?

Abandonment - is an abandonment/cleanup bonding component appropriate? Who pays in event of bankruptcy?

㉓ Sec. 2.1.1.7; Page 2-14.
Question: Are U. S. Coast Guard direct observations of ranges for wind strength and wave height and period available?

Sec. 2.1.1.7-2; Page 2-17.
Deficiency: Life of project forecast appropriate, as opposed to 5 year listed.

㉔ Sec. 2.1.1.7; Page 2-22.
Error: Green Point is a locally well known whale wintering ground. Whale populations are apparently expanding in numbers and by extension, area. Area use may well increase, though dependent on unexamined variables. Local memory (Indian tribes) may provide clues to post area usage and perhaps future distribution. Example: Both Quileute and Ozette River mouths were major aboriginal whaling sights because whales could be (and are) found as close in as the surf line. The Clallam Tribe took whales in the Straits, specifically offshore from Port Angeles spit.

㉕ Table 2.1.2.6-4; Page 2-60.
Error: Dungeness River specific conductance: listed mean outside listed range; Dosewallips River same.

㉖ Table 2.1.2.6-18; Page 2-81.
Omission: The following are legally defined as Lower Elwha Klallam Band usual and accustomed fishing area: Siebert Creek, Dungeness River, Jimmy Come Lately Creek, Salmon Creek, Snow Creek, Little Quilcene River, Big Quilicene River, Dosewallips River, Duckabush River, and Hamma Hamma River.

Fig. 2.1.2.6-2; Page 2-83, etc.
Mitigation: River crossings require low flow, and must occur at times of minimum juvenile and adult salmonid usage, probably early August. (Point also made by K. Gilliam, Elwha Hatchery manager). Effectiveness - minimize salmonid disruption. (Specifics should be case by case local concern determination)

㉗ Sec. 2.2.1.2; Page 2-154.
Question: Should future air quality trends be projected with the addition of a tourism traffic function?

㉘ Sec. 2.2.1.7; Page 2-155.
Deficiency: Oysters have been grown in Port Angeles Harbor (Peninsula College; 1970, 1971). Significant salmon potential exists in streams entering Port Angeles Harbor, planning is on going.

㉙ Sec. 3.1.7; Page 3-32.
Question: BLM should note the extent to which a river spill would produce avoidance behavior in up or down stream slamonid migrants? BLM should estimate the time this behavior might contribute to significant production decrease? (Paranoid speculation: Abortion or straying of major parts of spawning runs; residualization of out migrants with resultant competition/predation effects on 1 and possibly 2 succeeding brood years.) Do we know, or can we speculate on, the effects on redd site selection given the potential of silt/oil combination deposition?

Table 3.2.6.1; Page 3-68.
Mitigation: Take core samples of river crossings to proposed depth. Effectiveness - refinement of superficially examined composition statements; produce accurate estimates of sediment increase.

㉚ Table 3.2.5-4; Page 3-74.
Mitigation: See comments on table 2.1.2.6-18 (above). Note 5/ add "stray or delay." River spills will probably induce immediate fishing closures (consequent lost fishing time, income) which will last at least until effects are assessed. Mitigation should include preplanning and agreement for fishermen loss compensation. Effectiveness - continuance of community harmony and income.

Sec. 3.2.6; Page 3-75.
Deficiency: Sediment redistribution through spawning is noted. Spawning is keyed to upwelling percolation of water through substrate. If percolation is inhibited spawning activity may be redistributed and the ground lost, subject to on going clogging of intercises. The end result is a compacted situation relatively unproductive.

㉛ Paragraph 1,6,7; Page 3-78.
Question: Could the list of oil effects on freshwater organisms include behavior change in fish? Change in predation/competition dynamics in one year class component loss? Estimates of regulation change necessary to pass spawners through fisheries? Paragraph 1 - Add 5 and 6 years for some chinooks, potential for dominant year/age class change.

㉜ Sec. 7.11; Page 7-5.
Question: Does acceptance of this proposal mean the difference between adding a hydropower dam in Clallam County (or region) or not?

㉝ Page 4-6 and 4-8.
Deficiency: The boat launching facility on Ediz Hook has not been adequately dealt with. There are no areas elsewhere in the harbor that have enough room to handle the amount of boatmen that utilize this ramp, particularly in the months of June through September. Furthermore, there are occasional summer storms from the northwest that pose a great danger to small craft that would have to cross the harbor. At present these craft can make their way to safety by proceeding in the lee of Ediz Hook.

㉞ Page 4-3.
Comment: Local fishermen with considerable experience with wind and wave conditions in Port Angeles Harbor and the Straits find the provisions outlined for containing and cleaning up

126 CONT

㉞ spilled oil to be "ridiculous". It is quite common both in the harbor and outside for large logs to jump their containing boomsticks because of wave and chop action. To expect oil booms to contain oil under anything but optimal conditions is ludicrous.

㉟ Sec. 2.1.1.9; Page 2-26.
Deficiency: Several local sportsmen disagree strongly with the premise expressed that only endangered species or areas of special concern be addressed here. Many animals frequent the beaches at low-tide including deer, otter, raccoon, coyote. Even minor chronic spills could result in these animals being impacted by ingesting contaminated food or grooming themselves after walking and feeding in oil on the beaches.

㊱ Pages 2-16 and 2-17.
Deficiency: Several local fishermen with long time experience disagree with the tidal current projections outlined on these pages. The patterns do not meet with experience, are over-simplified, and do not give an accurate picture of oil dispersal in the event of spills.

㊲ Page 8-51.
Omission: No mention of impact on Hurd Creek fish hatchery for the "Cross-Sound" alternative.

㊳ Page 8-54.
Omission: No discussion of submarine pipeline spill impact on Sequim Bay. This area has a slow flushing action and contaminants could build up.

Page 8-54.
Omission: No discussion of impact of submarine pipeline spill on the commercial oyster beds in Dungeness Bay.

The NTPC project proposal requires over 400-more miles of new crude oil pipeline than any of the other major alternatives--requiring 66 major river crossings. Twenty of those crossings are in the Puget Sound Basin; 17 are in the Columbia Basin. In addition, there will be a minimum of 235 minor river crossings. Unavoidable adverse impacts would reduce salmon and trout populations due to sedimentation of spawning areas. "Severely reduced salmon populations might require 20-years for complete recovery." (BLM 1979)

*5-16 Par 8 and 9 It appears that if it will take up to 20 years for complete recovery of a destroyed salmon population, they might as well be written off as lost. Plans call for too few block or check valves creating an unnecssarily large risk of leak, spill, or rupture at several river crossings.

㊴ 2-115 Par 8: The Dungeness River is not included but should be since it is an important salmon and steelhead spawning river as well as being the source of water for irrigating a large area.

㊵ It should be noted that construction of two submarine lines would cause worst case water quality degradation for a period of minimum of three months as estimated by Northern Tier but could be much longer. The effects of this water condition should have received more thorough analysis by BLM.

This would involve removal of 1,550,000 cubic yards of marine sediments for two pipelines along Ediz Hook inside shore and to Green Point. Of this total 500,000 cubic yards would be recent marine sediments. This would be taken from sediment beds 11 to 16 feet deep inside Ediz Hook and ½ to 1 foot deep in Green Point area. Estimates of cubic yards is minimum.

One acre 1 foot deep equals 1300 cubic yards so the amount of sediment disturbance and removal is considerable and will impact the fishery. Thorough analysis of this impact should be performed by BLM.

Deficiency: It seems bottom fishing in harbor, Green Point area, halibut, blackmouth salmon in the harbor in the fall and winter months and the prime fishing spots for local, commercial, recreational and tourist fishermen are ignored.

㊶ Also, BLM should include the shrimp sports fishery inside Port Angeles Harbor. A favorite deep fishing hold for Haddock is off Green Point.

㊷ Deficiency: Under biological components either reference should be made to pages 3-26 to 3-28 or these materials should be given here, namely that in the "operational phase" dealing with oil spills and an area from Neah Bay to the Canadian shores to Lopez Island and North Central Whidbey Island affected species are molluscs, killer whales on migratory route, sports fisheries, harbor seal, river otter, clams, crabs, oysters, shrimp and large communities of waterfowl.

㊸ Sec. 3; Page 3-10.
Question: Will not the continuous sound of the pumping have an adverse effect on migrating salmon?

㊹ The BLM-DES should include economic impact analysis of potential oil spill impacts upon the fishery industry. Oil spill impacts can be severe to this industry (as experienced by spills such as the Amoco Cadiz): "Scientists say some 50,000 tons of oil, brought in by the tides, remains trapped below the surface in the sand at the Bay of Morlaix, where half of Brittany's oyster production is centered . . . it has been estimated that it still will be more than a decade before edible oysters can be grown in these Brittany mud flats." Also, other spills, such as the Torrey Canyon, can instruct us: "The torrey Canyon incident happened 11 years ago. The Cornwall coast has only this year shown signs of having fully recovered." (Christian Science Monitor, March 13, 1979).

Comment: Several local fishermen, with considerable experience are of the opinion that this document "fails miserably" to achieve its purpose. The information in many areas is inadequate, poorly documented, and "fails completely" to address many important considerations. Furthermore, several of these persons feel that in many areas the information is biased in favor of the applicant while ignoring undesirable aspects of this proposal. The fisheries section of the document is not adequate to access impacts in this very important area.

㊺ Table 3.2.6-4; Page 3-74.
Deficiency: East of the mouth of the Dungeness River is an extensive tract of hardshell clam beds. A spill from the pipeline crossing on the Upper Dungeness River could ultimately affect this resource. A discussion of this subject for all river crossings should be included. Also, the deltaic zone of the Dungeness is an extremely important spawning zone for pink salmon: at Jamestown, approximately 1.5 miles east of the Dungeness River's mouth, is an important nursery area for storry flounder. These aforementioned species could be significantly affected. Deserves a more thorough discussion.

CONT

㊻ Section 3.2.6; Page 3-75; Column 2; Para. 5.
Comment and deficiency: If only one year class of fish would be affected, how would this translate to pink salmon? As the Dungeness River supports pink salmon, it is possible that pink salmon so affected would not recover due to their two year cycle.

㊼ Section 3.2.6; Page 3-78; Column 2, Para. 2.
Deficiency: Statement is extremely general, making the assumption that all streams affected display uniform flow rates. The Dungeness River could not be considered comparable to McDonald Creek--which is what the statement suggests. This should be more specific and should entertain discussion relating to flow rates, source regions, and competency factors for all major stream crossings.

㊽ Section 3.2.7; Page 3-79; Page 2; Column 2.
Question: Physical components - construction phase. Statement again assumes a consistency (flow rate?) which cannot be proven. Flow rates vary seasonally and they vary specific to a stream's source region. If pipe crossings are close to spawning areas or river mouths, what would be the affect on fish and shellfish respectively?

㊾ Section 3.2.7; Page 3-89, Column 1; Para. 2.
Deficiency and question: The statement does not provide a definition of what a sublethal effect is. Does it refer to a specific minimum concentration of a soluable faction? This should be provided.

㊿ Sec. 1.4; Page 1-21, Table 1.1-7.
Deficiency: The criteria for determining a major stream or river should be reevaluated. All streams with significant fish or wildlife values should be considered as major and adequately identified and described in the FES.

(51) Sec. 1.4; Page 1-22, Table 1.4-8.
Omission: This table omits five counties in Washington. Many of the unidentified streams are major anadromous spawning streams, trout streams or have other significant wildlife values.

Sec. 1.4; Pages 1-44/47.
Deficiency: This complete section on pipeline laying is inadequate. It identifies a system of stream crossings that is in violation of Washington State Department of Fisheries standards. It is also too general to quantify the impacts outlined in the impacts section.

Sec. 1.4; Page 1-45, figure 1.4-13.
Deficiency: The drawing demonstrates inadequacy of identified stream crossing safety precautions. All stream crossings should have automatic shut off valves that are more responsive than the 50-100 barrel leak protection under the sound, and which will prevent the types of spills unidentified in Table 3.2.6.2 page 3-70.

Sec. 1.4; Page 1-46, para 1.
Deficiency: The discussed technique appears to violate standard provisions for approval by Washington Department of Fisheries. It also would probably not be approved under Section 404 for any crossings along the west side of Hood Canal since they all involve "aquatic life indigenous to the water body," (as described in CFR 323.4-3 paragraph 5b.4. of Section 404) which would be impacted and, many crossings are close enough to the mouths of streams to require permits because of concentrated shellfish production within the anticipated sediment outfall area. (CFR 323.4-3, paragraph 2).

Sec. 1.4; Page 1-56.
Comment: The discussion should identify that water withdrawals will be consistent with water-rights and low flow needs for fisheries.

Sec. 1.4; Page 1-57; column 1, para. 12.
Omission: There is no discussion about pre-blasting activities to reduce impacts to fish.

(52) Sec. 2.1.1.14; Page 2-37, Column 1, para. 7.
Deficiency: This habitat is a major sport fishery. Also the bottom fishery is a major fishery with heavy use and high success.

(53) Sec. 2.1.2.6; Page 2-57; Column 1, para. 4.
Deficiency: Major stream category should be expanded to cover all streams with significant fish and wildlife values, i.e. those requiring a Section 404 permit; those which local government has indicated to be significant, etc.

Sec. 2.1.2.6; Page 2-57; Table 2.1.2.6-1.
Deficiency: This table should be revised to be consistent with comment above.

Sec. 2.1.2.6; Page 2-57; Columns 1 and 2, para. 6.
Deficiency: Pipeline construction will have to coincide with fish activity. If there are migrating fish in a stream, construction will not be allowed in Washington. Statements that imply positive actions should be consistent with local, State and Federal regulations.

(54) Sec. 2.1.2.6; Page 2-78; Column 2, para. 3.
Deficiency: Both sediment-free water and sediment-free gravel is necessary.

(55) Sec. 2.1.2.6; Page 2-80; Table 2.1.2.6-17.
Deficiency: All streams with significant anadromous fish populations should be included in the table.

(56) Sec. 3.1.6; Page 3-14; Column 1, para. 6.
Omission: The impact of water withdrawals on fish should be discussed further.

(57) Sec. 3.1.6; Page 3-14; Column c, para. 1.
Omission: The bacteriacide to be used is not identified. Data to support water quality dilution needs of 5 to 1 should be included.

(58) Sec. 3.1.6; Page 3-15; para. 3.
Omission: Herring and smelt resources should be included.

(59) Sec. 3.1.6; Page 3-16; Column 1, para. 2.
Omission: There should be an extensive discussion regarding contamination of clambeds, and the beaches of Dungeness Spit.

CONT

(60) Sec. 3.1.7; Page 3-30; Photo
Deficiency: The photo illustrating waterfowl which have been in contact with oil does not demonstrate the serious nature of significant damage which oil can inflict on waterfowl. A photo illustrating fatalities due to oil contact would demonstrate the extent of possible impact better (when placing together with the other contrasting photo presented which reflects oil-free habitat).

(61) Sec. 3.1.7; Page 3-33; Table 3.1.7-9.
Deficiency:

1. Animal or Plant Group: This needs to be expanded to cover benthos and phytoplankton, detritus and other organisms at the bottom of the food chain.
2. Salt Marsh: This is one of the most important habitats to anadromous fish. Recent studies show juveniles feed in marshes during high tide and that marshes may contribute 80+ percent of food. Crustaceans, bottom fishes, fishes open water, invertebrates other than those identified, benthos and detritus would all have need and use salt marshes. Mechanical impacts to birds could be severe since birds use marsh areas for protection as well as feeding. Studies have shown that oil stays in salt marshes for long periods.
3. Eelgrass Beds - Fishes, Open Water: Herring spawning is very important. Oiling during spawning would have significant impacts.
4. Sand - Molluaks: Razor clams are a very important resource with a low resistance to oiling.
5. Mud - Molluska: Commercial oyster operations in Hood Canal could be destroyed by oil spills in the Olympic Mountains streams. If oil penetrates and is retained in the mud the area is lost for as many seasons as it takes the mud to clear.

(62) Sec. 3.1.7; Page 3-50; Column 2, para. 4.
Omission: The statement implies that fish are in the Straits in equal numbers all the time. This is not a correct assumption. In Puget Sound the Fraser River Run is extremely important and shortlived. If fishermen miss it they have lost much of their seasonal take. This is a very complex topic and it should be expanded and explained. Also, a worst case impact should be evaluated in 1978-79 dollars. It would seem logical to present a worst case scenario for the subject matter of this paragraph.

(63) Sec. 3.1.7; Page 3-50; Column 2, para. 5.
Omission: Assessment of losses should have been presented in the DES, and certainly in the FES. Canadian government studies related to the Thompson Inquiry may assist in this analysis.

(64) Sec. 3.1.7; Page 3-50, 51.
Omission: Impacts related to Canadian fishery should be adequately addressed in this section.

(65) Sec. 3.2.4; Page 3-61; Column 2, para. 3 & 4.
Deficiency: This statement is not consistent with previous statements about sesmic and geologic hazards along the corridor. Spring freshettes frequently have velocities of small outbursts along certain streams. The Dungeness River, for one, has serious erosion problems and could create problems. Alternative methods or locations for crossing such streams should be suggested and evaluated.

(66) Sec. 3.2.5; Page 3-63; para 1.
Deficiency: Since this topsoil is coming from a known source and contributing to degradation of stream quality it could fall under the NPDES guidelines for point source discharges. This should be investigated and discussed by BLM.

Sec. 3.2.6; Page 3-67; para. 4.
Deficiency: Flushing rates are variable and depend on the time of year material is deposited, type of material deposited and physical characteristics of a stream.

(67) Sec. 3.2.6; Page 3-67; column 2, para. 3.
Deficiency: There should be a discussion of the chemical composition of the water at flush.

(68) Sec. 3.2.6; Page 3-67; column 2, para. 2.
Comment: If short-term impacts occur at the right time it could eliminate a pink salmon run since they have a 2-year cycle.

(69) Sec. 2.3.5; Page 3-66; Column 1, para. 1.
Omission: BLM should include data relative to benthos and detritus production from marshes and other wetland habitats; what effect oil will have on this production; and, what impacts these could have on fish resources.

(70) Sec. 3.2.5; Page 3-68; Table 3.2.6-1.
Omission: This table displays actions and does not address impacts. It should identify: (1) Duration of time span the sediment will impact each stream, (2) Sediment draft distance, and (3) the estimated deposition zone from the source-point to the point of zero deposit.

(71) Sec. 3.2.5; Page 3-72; Column 2, para. 6.
Deficiency: This statement implies an action that cannot occur. Due to screening criteria, no fish will enter the pipe. If fish start entering the pipe, pumping will be shut down.

(72) Sc. 5.1.6; Page 5-5, para. 2.
Omission: The impacts of the reduction of a base flow of 0.5 percent on fish activities throughout the year should be discussed more thoroughly.

Sec. 5.1.6; Page 5-5; para. 2.
Omission: Further study must be made of the impacts of siltation in Seibert Creek on fish; the maximum level turbidity factors will reach; and, the effects on $O_2$ levels.

(73) Sec. 5.1.6; Page 5-5; para. 2.
Omission: Reviewers have discussed various aspects of dumping of excessive amounts of water used for testing tanks, etc. into Seibert Creek. What impacts would this have on fish resources at different times of the year? BLM language is a statement and not an identification of impacts.

(74) Sec. 5.1.7; Page 5-5.
Omission: Marine Resources - Construction phase identifies numerous sediments nutrients, solubles, etc. and relates how these coule reduce oxygen levels, and increase chemical and biochemical contamination of sea water. The Biological Components section fails to discuss mortalities

CONT

(74) due to the oxygen failure addressed in Physical Components. The impacts are generalized and somewhat abstractional. The document never says what may really happen in numbers of fish that could be lost if conditions were right or loss of revenue if the chemical build up in fish did occur. A worse case scenerio should be presented. in compliance with NEPA.

(75) Sec. 5.1.7; Page 5-5,6.
Deficiency: Describe the aquatic resources of Seibert Creek - its fishery and probable effects of discharges from the project on this. What restitution is to be made for the loss of this public resource?

Comment: Throughout the BLM document there are many references related to fishery. However, there is insufficient analysis regarding the economic value of the area fishery.

J

## FOREST PRODUCTS

The forest products industry would be impacted by this proposal. The mills are particularly vulnerable because this proposal impacts on them in several vital areas such as electrical power, air quality, log storage, and water quality.

Both ITT-Rayonier and Crown Zellerbach purchase their power through the City of Port Angeles and both have faced, and in Rayonier's case is continuing to face, needs for significant increases in electrical power. A large part of this need was necessitated in both cases by requirements that the mills clean up their air and water emissions. Northern Tier should be obligated to secure their own electrical power without any attempts to take power that has already been allocated to the mills.

Air quality is an area where both mills have made great strides to clean up their air emissions. Again, no burdens should be placed on local industry to take additional expensive steps to clean up their air emissions if a significant deterioration of air quality appears possible from oil unloading operations at the marine terminal. The analysis should be on the basis of what steps Northern Tier is going to take to insure that the impact on air quality will not be significant.

An acute problem of immediate significance is that of log storage within Port Angeles harbor. Northern Tier has staked out an area for their marine terminal which would take a large area now used for log storage. Although the entire log storage area is not full, this is done for the purpose of having room to maneuver the logs so that a specific type of log can be sorted out to meet a specific need at the mill. If the mills were denied log storage or had it severely reduced, it would have a substantial financial impact on the mills. Dry-land storage and handling of logs is a great deal more difficult and expensive than water storage. In the case of ITT-Rayonier, it would significantly contribute to the air quality problem in downtown Port Angeles because of the large increase in the number of trucks that would have to traverse the downtown area.

The concern over water quality is quite similar to that of air quality in that both major mills have made great strides in cleaning up their water effluent. In ITT-Rayonier's case they are in the process of converting to secondary treatment at great expense in order to insure water quality remains at a high level. Again, no burdens should be placed on the mills for additional improvements if it appears that Northern Tier's operation would result in a serious deterioration of water quality. Northern Tier's proposal must be analyzed from the point of view of what steps is it necessary for Northern Tier to take to insure water quality remains at its present high level.

❶ Deficiency: The effect of losing over 117 acres of water storage area will force I.T.T. and Pen Ply to utilize more dry land storage, thus causing loss of additional farm and forest land to log dumps which in turn impacts living qualities of rural residents, loss of producing forest and agricultural land, causes greater fuel consumption by trucks and log-loading equipment. Industry estimates show a $20 - $25 per thousand increase in log handling costs for export logs. The BLM should address this concern.

❷ Omission: Forest land problems created by the building of the tank farm and pipe line relate primarily to property lost to forest production. No discussion is put forth nor reasons given for taking a 90 foot swath of producing land next to non-producing Bonneville right-of-way. Reasons should be given for not using the existing cleared Bonneville right-of-way for pipe line burial. No effort has been made to tell how land is to be used productively following line construction nor how much future economic effect the removal of producing agricultrual and forest land will have.

❸ Omission: The current proposal, and any petroleum-related secondary expansion at or near the proposed tank farm site will impact the productivity of seed orchards to the east of the site. Also, the impacts of air polution on Christmas tree production and agricultural production is not fully addressed.

❹ Sect. 3.1.12; P.3-41.
Question: What will be the impact of both chronic spillage and periodic large spills on the log inventory in the harbor? Industry sources have mixed opinions regarding the level of significant danger caused by the contact of oil with the water-stored log inventories. Some sources indicate a decrease in value for some uses (primarily pulp production and export) if logs were oil soaked in any significant degree. The BLM should research and further discuss the possible economic impact.

## GEOLOGY

K

❶ Deficiency: This section is not adequate. See the Dames and Moore studies of Clallam County for a nuclear power plant. See the Geology maps in the State Department of Geology under DNR in Olympia. Dr. Rogers' study of the area would be pertinent (University of Washington PhD Thesis). There is not time for us to do the research to cite all the errors and omissions in this section, but they are numerous: faults along the Hood Canal are believed to be active, probable fault along the Strait of Juan de Fuca, probable faults along the valleys in Port Angeles pointing at the berthing facility, evidence of severe faulting at the end of Miller Peninsula, question of migration of the Olympic Peninsula away from inner Puget Sound area, known geologically active fault on Dow Mountain near the south end of Hood Canal, known earthquake epicenter under Blyn Mountain very close to the pipeline route. The evidence of geologic instability was the reason given for the abandonment of the nuclear power plant in eastern Clallam County.

126 CONT

② Sec. 3.1.4; Page 3-10.11.12.
Omission: The summary neglects to mention the possibility that the project itself may cause erosion of Dungeness Hook due to interference with littoral drift as the three submarine pipelines ascend the bank to the storage facility. The change in the harbor bottom by placement of the pipeline from Ediz Hook to shore may prove highly significant in light of the practice of ships to drop and drag anchor at the entrance of the harbor as a braking mechanism. The injection of water into the soil at the tank farm for waste disposal may lubricate the nearby bluff area and contribute to landsliding. What studies have been made of this process? Some further information is needed to determine whether this will aggravate the landsliding already endangering the residential development to the west of the tank farm site. The entire presentation on soil stability is seriously deficient as is description of known earthquake epicenters and faults in the area.

③ As to the harbor construction having negligible effects, there is no discussion of changes in circulation of water within the harbor by the docks, ships, booms, etc. which might well affect the deposition of geologic materials. Will the pipeline across the harbor act as a sill to retain sediments at the harbor bottom?

④ How and to what extent will the permeability, porosity, cementation and moisture content of the soils at Green Point be changed by the project? As is characteristic of this document, the references cited are insufficient and not available to the reviewer.

⑤ In discussing slope failure on the west side of Ediz Hook caused by pile driving and laying pipe on the east side, it should be noted that the Hook has been eroding with threatened loss of the harbor and is being shored up by rip rap on the western side. Where was the breach in relation to the project site? Please give cross section to scale of the Hook at the project site with and without the project in place. What is the risk of adding to the earlier breach?

⑥ At abandonment, why would submarine pipes be allowed to be left to rust with oil contaminated water in them? Why shouldn't they be pulled out?

⑦ Sec. 3.1.5.
Question: What "fluid leaks" are expected in addition to oil leaks? Diesel? Chlorinated hydrocarbons?

⑧ Sec. 1.4; Page 1-45.
Deficiency: Figure 1.4-12 should also show plans for pipeline burial in various unstable earth conditions (i.e., clay, fractured rock bentonites, slip or slump areas, etc.).

Deficiency: No provision is made within the pipeline trench to contain an oil spill. Leak detection to only .5% means that 4600+/- barrels could be indectectably lost per day at maximum flow. This quantity of oil cannot be allowed to soak into the ground. BLM must analyze this matter further and require more safeguards.

⑨ Deficiency: Outburst flooding: obviously the Dungeness River is capable of this kind of action with intense scouring in the course of flooding. What other rivers have potential for ripping out or damaging the pipeline either from water scour and pressure or from heavy debris dragging into the stream bottom? Give the frequency of major flood events for the larger rivers.

Deficiency: Figure 1.4-13 does not show adequate protection to the river in the event of a pipe rupture.

Sec. 1.4; Page 1-46.
Deficiency: Backfilling procedures for streambeds should be carefully chosen to prevent scouring and to blend in with the existing bottom. If the river is in a downcutting stage, steps must be taken to stabilize the bed.

⑩ Sec. 1.4.
Omission: Foundation bearing characteristics for the tank farm should already be known partially from analysis of core samples. Where is this data? Is this Vashon Drift material or something else? Such data belong in an urgently needed Technical Addendum.

⑪ Sec. 2.1.1.4; Page 2-11.
Omission: It should be noted that in road cuts to the south and west of the tank farm property, a varying degree of soil stability is displayed. A more detailed examination of the property is required.

⑫ Sec. 3.1.4; Page 3-11.
Omission: There is no explanation as to where the fill material comes from, or where the spoils are taken. The quantities involved could have major topographic effects on the source areas.

⑬ Sec. 1.1.
Omission: In discussing surplus excavation materials and control of erosion, please describe quantities of sediment likely to escape the site into Seibert Creek or the Strait. How will resonable limits for erosion be set? How monitored? What provision will be made for enforcement of this? (Will a performance bond be posted?)

⑭ Sec. 3.1.4; Page 3-11.
Deficiency: The cutting of the launchway ramp in the bluff at Green Point could create major instability problems. Special design features for this structure should be outlined.
Discussion should includd design critera vis-a-vis high wind and wave action.

⑮ Sec. 3.1.4; Page 3-11.
Deficiency: Under the heading Geologic Hazards, nothing is said about the effect of alterations of the bluff at Green Point on the dynamic, geohydraulic conditions that maintain the Dungeness Spit. Interference with the process of shoreline drift predictably causes problems in the deposition area. The effect of this alteration on the "largest federal waterfowl refuge in Washington state" (page 2-22) must be considered more fully than in a single sentence buried on page 6-2. Displacement of fish migrating along the shoreline must also be addressed, along with bottom and other fishery.

⑯ Sec. 2.1.1.4; Page 2-11.
Deficiency: The bluffs along the shore at Green Point are rapidly eroding and serve to feed Dungeness Spit.

CONT

⑯ The entire shoreline from Port Angeles to the base of Dungeness Spit was placed in a conservancy environment and removed from intense residential development despite wonderful view property for the reason of this instability.

Sec. 2.1.1.4; Page 2-11 (con't.)
from intense residential development despite wonderful view property for the reason of this instability.

Although Shannon and Wilson reported that the bluffs are "relatively stable," Ralph Kealer, shoreline specialist for the U.S. Geological Survey, has stated that the average erosion rate for the bluffs in the area is 20 to 40 inches per year. (Seattle Times, 2/10/79)

⑰ Deficiency: Please give the full report of Shannon and Wilson for the soil cores done at the tank farm and harbor sites. What was their report regarding liquefaction under seismic conditions? Regarding weight bearing capability?

Sec. 3.2.4; Page 3-59.
Omission: Excavation and grading for the pipeline might also intercept and/or divert some shallow aquifers. Steps should be taken to protect these water sources.

⑱ Sec. 3.2.5; Page 3-65.
Omission: This section speaks only about soil contamination. There should be some note about groundwater contamination.

⑲ Sec. 4.4; Page 4.2.
Omission: Mitigating measures for the topographic disturbance at the Green Point Bluff should be discussed.

Sec. 5.1.5; Page 5-3.
Deficiency: Settling basins should be designed with maximum rainfall conditions in mind. Unusually high rainfall might seriously damage the slopes in the launch ramp.

⑳ Sec. 5.2.4; Page 5-13.
Question: BLM presents predictions of geologic events for a 20 year expected life, but state that the pipeline may have a much longer life. Shouldn't the events be predicted on a maximum lifetime?

㉑ Page 2-52.
Question: What two surface rupture faults are you referring to in Washington state on page 2-52?

㉒ Page 2-53.
Deficiency: Liquefaction: Where in Washington are the areas identified where the pipeline could be affected by this and what measures will be taken to offset this? Were the marshy areas along Hood Canal included? The unstable soils at Green Point?

㉓ Landslides: Where in Washington are landslide areas capable of causing pipeline rupture? What is the frequency and magnitude of slides in these areas? What measures are proposed to offset this?

㉔ Sec. 7.2.2; Page 7-2.
Question: It is stated elsewhere that oil saturated soil might be removed. In this section, it is stated that reclamation is through tilling and nutrients. Which is planned?

Sec. 1.4; Page 1-14.
Deficiency: A paragraph discusses the permiability of onsite soils relative to their use as dikes. If they are found to be unacceptable, material will have to be brought in for the dikes and the floor of the catch basins. (The permiability of the floor of the basin is never discussed.)

Sec. 2; Page 2-154.
Comment: Physical components: A very good and accurate statement.

Paragraph 22, Page 1-58.
Deficiency: This comment is inconsistent with other statements in the DES that discuss slope stabilization at stream crossings.

㉕ Page 3-13; Columb 1, para. 3.
Omission: There is no discussion of where these 680 to 1,540 tons of soil will go. The statement about erosion on the coastal bluff needs to be more adequately documented.

㉖ Question: Will compression of subsoil water bearing layers by the weight of the tanks alter water courses so as to aggravate further the erosion problems along the bluff near the subdivision?

Omission: Table 5.1-4 does not indicate loss of wildlife and fish and shellfish habitats and subsequent wildlife and fisheries losses to slides, etc. discussed under construction. Also, there is no discussion of the effect a major slide would have on the natural erosion cycle of the bluff or what effect tidal washing of excessive amounts of materials would have on Dungeness Spit.

㉗ Page 5-2, 5.1.5.
Omission: There is no discussion of soil loss on the bluff at Green Point.

Page 5-5, 5.1.6.
Omission: There is no discussion of possible impacts on the shoreline from installing the pipeline and the trough on the bluff at Green Point.

Page 7-2; 7.1.1
Omission: Discussion of alteration of Green Point Bluff and possible alteration of Dungeness Spit needs to be included.

L

## HARBOR MANAGEMENT

Some comments related to the harbor are discussed in other sections of this report, including "Water Quality", "Fisheries", "Air Quality", "Recreation and Tourism".

Section 1.1; Page 6-1; Para. 1.
Question: At what point are the cumulative impacts of 3 tanker berths 3 submarine lines and 35 tanks at the onshore facility addressed adequately? Air quality, noise, vessel traffic, bluff erosion are a few areas of concern.

① Sec.1.1; Page 1-5; col. 1.
Question: There appears to be an inconsistancy here. A part of table 1.3-1 summarized states the Department of the Army is the

CONT

① activity required to approve dredging of the Port. Also that the Environmental Protection Agency must approve the disposal of dredge material. Par. 2 Page 1-7 states "... dredging would not be required."

② Page 1-48.
Deficiency: What disposal is made of an in-bound, filled tanker 24 hours away which is having mechanical problems affecting control of the ship? What disposal is made of a vessel entering the harbor with a fire on board? What is done with a ship at the moorage with a fire on board? (minor and major fires to be considered).

③ Deficiency: The issue of storage and handling of bunker fuel has not been addressed adequately. Different possibilities should be addressed (i.e. fuel from Washington refineries; fuel from California; storage in tankers on Ediz Hook; storage in barges; etc.)

④ Sec. 1.1; Page 1-50; Col. 1.
Deficiency: Although the project has a projected life span of 20 years, page 1-50 states that berthing structures would probably not be taken out of service. Why not? What industries would they be supporting?

⑤ Section 1.4; page 1-49.
Deficinecy: The ES indicated that the terminal dispatcher will advise the tanker personnel which anchorage area to occupy. Are there anchorage areas designated in the Port Angeles area? The ES does not discuss the possible location of any anchorage areas. Anchorage within the harbor for a so called "super tanker" is very limited and probably could not be permitted with the present traffic in the harbor and the number of vessels which presently anchor there.

⑥ Section 2.1.1.13; Page 2-32; Para. 2. Also Table 2.1.1.13-3 and Map III-4 Addendum.
"Piers" might be better described as berths. There certainly are not 30 projections into the harbor for docking, but rather far fewer projections able to moor vessels of varing kinds. Also Map does not designate all "pier" areas listed, i.e., Port of Port Angeles log shipping, M & R Timber dock, nor Port Boat Haven, etc.

⑦ Section 1; Page 2-35.
Deficiency: "Although the line is satisfactory for current use" and speaks to need for new slip barge at Port Townsend, rail abandonment (page 2-156) discussions locally project a potential need for a Port Angeles Rail barge slip. Present use of rail line is less than adequate because of restricted load limits placed on shippers. (Source: Crown Z communication, Dec. 1978 regarding load limits; slip and barge information in local newspaper). Where could the new rail barge slip be located in the Port Angeles harbor?

Page 3-42, col. 1 & 2.
Deficinecy: Does not speak to total project throughput of 1.3 mbpd.

Deficiency: Does not adequately discuss fuel barge traffic impacts relating to both two berth operation and total project operation for throughput 1.3 mbpd.

Deficiency: How many additional tugs and towboats will be needed for total project operation?

⑧ Deficiency: Statistics for vessel traffic given for Straits for 1976. What are increases for 1977, 1978 and projected future increases related to economic growth in Puget Sound area? Also increases for local harbor vessel traffic? Source of data?

⑨ Question: Where would extra tugboats and fuel barges anchor?

⑩ Deficiency: Does not adequately speak to tanker queing problems, location of anchorage areas, possible economic impact by forced waiting periods for other vessels, or related hazards to this kind of traffic congestion, and weather conditions.

⑪ Deficiency: What is space occupancy required for anchorage of 325,000 dwt tankers? How close can another vessel safely anchor? Who would designate and enforce anchorage areas?

⑫ Para. 3, col. 2.
Deficiency: What impact would vessels trying to leave harbor in case of a fire have on other vessel safety and capability of dealing with fire in a small enclosed harbor?

⑬ Deficiency: How wide a space is required for tanker approach lane in harbor? Is it safe for a 325,000 dwt tanker to enter harbor with simultaneous meeting of departing loaded log ship or passenger ferry Coho? Is there room for same? Other moving traffic?

⑭ Para. 3, col 2; Page 3-42.
Deficiency: Does not speak to combined total vessel traffic relating to risk factors for fires and explosions in the harbor. Does not include tugs, fuel barges, ferry trips, commercial and recreational boating as related to total traffic. Does not include increased growth vessel traffic all classes for seven year period from 1976 adding the five year time lapse for Northern Tier 933,000 throughput.

⑮ Error: Discrepency in explosion or fire statistics. Gives one in 12.24 years and 15.62 years respectively for 390 calls per day. Site Certification states (Vol. 3 pt. 2) one in every 11 years for 395 tanker port calls. Neither figure relates (2.11-49) to risk factor in enclosed harbor from other vessel probability.

⑯ Question: Data source for explosion and fire statistics? What would be distances for vessels from tankers at berth, in turning departure pattern, in vessel approach lane with ongoing moving traffic?

⑰ Deficiency: Does not speak to loss of steering or grounding of tanker onshore or to collision from other moving vessel relating to fire and explosion potential.

⑱ Sec. 3.1.13; Page 3-42; col. 2, para. 4.
Deficiency: "Would most likely remain in place" as abandonment procedure for submarine pipeline is not valid.

⑲ Sec. 2.1.1.14; Page 2-37
Deficiency/Omission: The number of passengers carried to and from Victoria on the ferry Coho should also be listed. Especially peaks and lows, as well as averages.

⑳ Sec. 2.1.1.5; Page 2-38.
Deficiency: Why use Arco for data source of traffic in Strait? Puget Sound pilots would be a much more accurate source. Does Puget Sound have less vessel shipping than Victoria/Vancouver area? The Strait is the trunkline to Puget Sound for vessel shipping also. Are there more tankers than other types of freight vessels going to Washington ports? Doubtful! V.T.S. is presently only for traffic east of Port Angeles.

㉑ Table 2.1.1.15-1.
Average day figures are inaccurate for all vessels.

㉒ Sec. 2.1.1.15; Page 2-38; Col. 2, para. 3.
Again, question use of area figures rather than Coast Guard and Puget Sound pilots.

CONT

㉓ Page 2-39; Para. 1.
According to 13th Coast Guard Dist. Public Affairs Officer, VTS regulations do not require ferries on scheduled runs to report their movements except during periods of low visibility or darkness. Source: Seattle Post Intelligencer 1/17/79 "Vessel Traffic System Blamed for Collision." Were Arco figures based on vessel numbers or vessel trips?

㉔ Table 2.1.1.15-2; Page 2-39.
Deficiency: Why was a similar table not developed for U. S. ownership of commerical fishing and household pleasure boats in the Straits to the Port Townsend area?

㉕ Table 2.1.1.15; Para. 1; Page 2-41.
There occurs a biased statement in 2nd sentence. Uses are not limited to serving the forest product industries and as a refuge for tankers and other vessels in transit. If such were correct, why should we change one limiting industry for another much more potentially polluting and hazardous one. The harbor does serve the needs of the forest industry since it is a major employer in the area. It also serves as a fish buying station for commercial fishermen; as the international gateway to Victoria via the ferry Coho for tourists; provides recreational fishing not only locally, but for people coming from all parts of the U. S. Harbor limiting factors are its size, primarily.

㉖ Table 2.1.1.15-8; Page 2-42
Deficiency: Why were intra-harbor movements excluded from the table? Why were 1977 figures not used? Were commercial fishing catches entering harbor included in the table? If no, why not? Why was data adjusted relative to foreign oil imports? Why was vessel count not also used?

㉗ Para. 2; Page 2-42.
Deficiency/Error: The last sentence appears to be a comment not based upon fact. Many motel owners rent to college students during off season which is a steady income use supplementing summer tourist season peak usage.

㉘ Table 2.2.1.13; Page 2-155; Para. 1.
Deficiency/Error/Question: "However, because of the harbor's deep-draft capabilities, it could become a commodity transshipment point with large bulk carriers off loading commodities for transshipment via smaller vessels or barges to other ports." Then on page 6-1 under "Tanker Unloading Berths" Para. 3 "The commitment of the harbor resources to the proposed project could deter the development of additional deep draft piers to handle commodities other than crude oil during the short term." Short term is defined in Para. 2 of Page 6-1 under 6. The relationship between local short term, etc. (at top of page). "Short term will be the 20 year life time on which the project economics have been based." Continued reading under tanker unloading and on page 2 provides more details. Page 6-1 speaks to future harbor growth restrictions. Yet para. 1 of tanker unloading berths, on the same page, speaks of existing uses being restricted, moved or discontinued. What is the economic impact and loss to the community of the short and long term?

㉙ Sec. 2.2.14; Page 2-156; Col. 1, para. 6.
The elimination of not only present boat launch facilities should be addressed, but also, limitation on future boat launching facilities should be discussed.

㉚ Sec. 3.1.7; Page 3-34; Col. 2, para. 2.
Deficiency: "If" is not proper procedure description for abandonment phase. What effect on Ediz Hook soil erosion, soil stability would removal of hugh pilings along shoreline have? What effect would ongoing vessel traffic and other uses have on anchor damage or other damage to submarine pipelines if left in place?

㉛ Para. 2; Page 3-39.
Deficiency: All impacts mentioned will not only be combined impacts during minimum 18 month construction period only to project impact but must be combined and related to already existing community impacts in port and onshore facilities.

㉜ Sec. 3.1.13; Page 3-39; Col. 2, para. 2
Question: Northern Tier project would force removal and relocation of existing industrial and recreational uses in the harbor area. How can future industrial development be spoken to in terms of lesser attractivenessfor an industrial site which would then be fully occupied? Para. 2, page 3-39 states no other harbor areas available.

㉝ Page 3-39; Column 2; Paragraph 2.
Deficiency: What is exact acreage of harbor and tideland current mill usage by Crown Zellerbach and ITT Rayonier forced to vacate to Northern Tier project? About 55% could result in further industrial curtailment.

Deficiency: Does not speak to location displacement site for six or more chip barges requiring harbor ingress and egress, storage and access availability for continuing mill operation Crown Z and ITT Rayonier.

Deficiency: An at-random choice of mill log storage relocation suggested as adequate by Northern Tier is inadequate. Said relocation related to two separate current operating industries with significant economic impact on community at large, and impacts must be related to same, both short and long-term.

Deficiency: Does not speak to additional economic, traffic and air quality impacts as added to current existing, additional Northern Tier impacts and increased and total combined impacts totaled for all areas.

Deficiency: Impact stated in all cases relate to initial construction and not impacts related to total project.

㉞ Section 3.1.12; Page 3-39.
Deficiency: The DES indicated that existing log storage area, pilot station, V.O.R. station and marina and boat ramp for small boats would be displaced. The FES should discuss specific sites to relocate these facilities. Providing no site is available to relocate any one of these facilities the FES should discuss the impact the closing of these facilities will have on the community. The FES should also address at whose expense would they be moved!

Paragraph 3; Col. 2; Page 3-39.
Deficiency: Does not give specific relocation sites available for pilot's station, Thunderbird Boathouse. What impact, what less desirable location on each entity have and also impact added to restricted access for all entities?

㉟ Question: Why is the possibility of relocating the pilot's station to the Coast Guard base given as an alternate when the Coast Guard base itself will be restricted in current usage from initial construction and impacted to an unspecified degree with total project operation?

㊱ Deficiency: Does not speak to safety problems and hazards related to restricted uses and less desirable locations for pilot's station, Thunderbird Boathouse and boat launches.

Deficiency: Does not address possibility of loss of pilot's station and Coast Guard to another area location by Northern Tier project, and economic loss related thereto.

120

㊱ Deficiency: Exact land site description and availability for relocation of pilot's station, Thunderbird Boathouse and related buildings necessary and availability of parking space.

Deficiency: Where would relocation of public beach land now available on Ediz Hook be relocated?

Deficiency: Does not speak to specific impact on U. S. Coast Guard during initial construction and further impact from total project impact on Coast Guard station.

Deficiency: Does not specify exactly how much and at what site any recreational public land or beach use on Ediz Hook would be available for use and tolerable for current public uses. What impact second phase for total project?

Deficiency: Does not give usage impact restriction for current continued use Peninsula Plywood Log Dump during construction? What impact from construction total project?

Deficiency: Does not give impact and specific restrictions on current usage for Foss Tug during construction. What impact from construction second phase total project?

Deficiency: Does not give specific restrictions on current and ongoing useage by Crown Zellerbach during construction. Impact on second phase construction total project?

Deficiency: Does not identify intensities and restrictions related to each individual user. Impact must be given for combined impacts with already existing impacts and effect on land users including residential community. Also combined total impacts during second construction phase for total project.

Deficiency: Specific impact to all harbor users during construction when harbor entrance partially constricted for minimum of three month period. (Vol. 3, part 2, Site Cert. N. Tier Pipeline, Page 2.10-3)
Sec. 3.1.12; Page 3-40; Col. 2, para. 1.
Error: To state future industrial harbor use might be affected by project is not correct statement when in reality current industrial and recreational use of harbor and land areas must be relocated for initial phase of construction.

Question: Would total project construction force relocation of other industrial and recreational usage?

㊲ Section 3.1.12; Page 3-41.
Deficiency: The first paragraph should explain the impacts of a major oil spill on harbor industries.

㊳ Paragraph 1, Col. 1; Page 3-42.
Deficiency: Tourist season definition for June-September is too narrow a scope.

Question: Would there be vessel anchorage for current harbor users during 3 month minimum period given for restriction of harbor entry usage? Economic impact?

Error: States June-September recreational use of harbor will be at maximum during construction 1980. Site certification, vol. 3, part 2, pate 2.20-6 states construction by Northern Tier will render existing boat launching and mooring facilities on Ediz Hook unusable.

Error: Assumes bottom pull method of submarine pipe laying. Method is not specified in proposal (either jetting or bottom pull).

Deficiency: What is total number of barges, tugs, launches and other water related equipment and space occupancy area required for same in harbor which Northern Tier will be using at maximum construction peak?

Deficiency: What effect will construction activity have on interference with Port Angeles-Victoria ferry scheduled runs?

㊴ Paragraph 1, Col. 1; Page 3-46.
Deficiency: Does not adequately address the restrictions and impact on Coast Guard Air Operation with 175 high tankers, 80 foot towers, marine arms, all located approximately 600 feet offset from runway centerline and 600 feet from threshold. "Might be construed as hazards" does not properly address impact on Coast Guard facility.

㊵ Paragraph 2, Col. 1; Page 3-50.
Error: Does not speak to two boat launches at Ediz Hook which would be displaced. One is for smaller boats and is not used during winter months.

Deficiency: Does not state relocation costs and operating losses for mill log storage, Thunderbird Boathouse and two boat launches.

Deficiency: Must address relocation impact of recreational facilities in terms of not only financial loss to the operator or associated costs but in terms of public land use intent and water access for recreational purposes. Must also include impacts from loss of public beach land on Ediz Hook, impact from restricted usage by relocation and economic cost to users if sites lost to local harbor in terms of insufficient related facilities now available and distance traveled for usage.

㊶ Paragraph 2, Col. 2; Page 3-54.
Deficiency: Does not adequately address impact of inhibited recreational boating in the harbor (inhibit means to forbid or restrict). What effect would this have on Salmon Derby and all other recreational related related activities during operation?

Deficiency: Does not speak to economic, social and recreational impact on community as result of loss of or restricted use of harbor area.

㊷ Section 4.13; Page 4-7.
Deficiency/Question: The ES indicates that pleasure and fishing craft would not be allowed within a predetermined distance of tankers discharging crude oil. The ES should indicate this distance and discuss the impact this will have on pleasure and fishing craft. Also will there be restrictions for other harbor traffic?

㊸ Sec. 5.1-12; Page 5-8; Col. 2, Table 5.1.12-1.
Question: What are the economic and energy impacts of "the" one re-construction and operation of the Thunderbird Boathouse facility, log storage areas, the pilot station, one public boat launch if they are to be relocated?

Sec. 5.1.12; Page 5-8.
Deficiency: In one land use discussion, the operation of the planned municipal pier should be addressed.

Section 5.1.12; Page 5-8.
Deficiency/Omission/Error/Question: There are a number of proposals under active consideration for harbor usage, some with very significant impacts. Why were these proposals not addressed? Anyone reading the local Daily and Seattle newspapers would have an awareness of proposals. Why were possible harbor use option foreclosures not detailed and described? The Port of Port Angeles and the Port Angeles Chamber of Commerce should be contacted for current information.

Table 5.1.12; Page 5-8.
Deficiency/Omission/Error/Question/Mitigation: Location of project

CONT

㊸ as described is too vague to determine displacement of amount of log storage. What are impacts of additional log traffic on city streets (i.e., traffic control and street maintenance?) Location of log storage land available should be noted. What effect will dry land log storage have on air quality and noise pollution? What impact would dry land log storage costs have on the competitive ability of local industry in the pulp and paper processing markets?

Section 2; Table 5.1.12-1; Page 5-8.
Deficiency/Omission/Question/Mitigation: An alternate location should be acquired for the pilot station. Why has this not been done by applicant? Who would be responsible for relocation costs?

Section 3; Talbe 5.1.12-1; Page 5-8.
Deficiency/Omission/Question/Mitigation/: An alternate site within the harbor should be identified for the Thunderbird Boat Marina and 2 public boat launch ramps. Why has this been neglected by applicant after assuring the community it would be done? Who would be responsible for relocation costs of public boat launch sites? What is the impact on regional recreation, the community and the tourist industry?

Section 5; Table 5.1.12-1; Page 5-8.
Deficiency/Omission/Error/Question: "Nuisance" is an error. What specifically will the Northern Tier proposal impacts be to the Coast Guard base, harbor log and chip barge storage, recreational use of the harbor, Crown Zellerbach mill (including motor vehicle traffic) and vessel traffic in the harbor? None of these have been adequately addressed under description of project, impacts or mitigating measures. What are the cost factors involved in these impacts?

㊹ Section 5.1.13; Para. 1 & 2; Page 5-9.
Deficiency/Omission/Error/Question: Where will tanker queueing take place, in the harbor or elsewhere? How large is the non-anchorage area to be over the submarine pipelines? Why has it not been designated or shown in diagram form? Exactly what impact will increased tanker traffic and queueing have on restricting present incoming and outgoing vessel traffic (i.e., log booms, barges, log ships, the ferry Coho, commercial fishing boats and recreational boating - both motor and sail)? What will the impact be on inner harbor movement of log rafts and chip barge movement from one place to another within the harbor? What impact would restricted anchorage area designation have on present vessel anchorage? How would a VLCC, 325,000 DWT tanker at anchor in the harbor affect or restrict existing harbor traffic usage and vessel movement? How many tankers of what size could be anchored in the harbor and still have the present normal vessel traffic movement? Where outside the harbor would waiting tankers anchor? What specifically would be the "occasional inconvenience to other commercial vessel traffic?" Is this local commercial vessel traffic or is it commercial traffic going in sound or out to sea? Or both?

Section 5.1.13; Sec. #2; Page 5-9.
Deficiency/Omission/Error/Question: If VOR (Vertical Omni Range) station would need to be relocated, there would, not could be, adverse impacts on air navigation. Why has an alternate site for the VOR not been located? Who would be responsible for relocation cost? VOR interference - what impact would it have on the safe navigation of aircraft flying the the area? How major an undertaking is the relocating of the VOR station? What else on the Coast Guard base will need to be relocated if Northern Tier locates on Ediz Hook?

Deficiency: The BLM-DES is inadequate in its coverage of maintenance and repair of tankers, tugs, fuel lighters, etc., utilizing the port if an oilport is sited in Port Angeles. This issue should be addressed thoroughly.

㊺ Sec. 6.1; Page 6-1; Para. 3.
Deficiency/Question: A 20 plus year commitment of the harbor to the Northern Tier project with both immediate and long term restrictions on industrial and recreational uses are an economic strangulation for the community. The benefits of other harbor uses should be evaluated. The NEPA requires such analysis of long term versus short term benefits.

㊻ Sec. 6.1; Page 6-7; Col. 1, para. 1.
Error: The Oceanographic Commission of Washington in a 1975 offshore oil study addresses the topic of the siting of refineries and petrochemical plants in a different manner. "Offshore Petroleum Transfer Systems For Washington State." Feasibility study. Page IV, 157, last paragraph, Page IV, 158, first paragraph. BLM should further research this topic (additional discussion of this topic in the "Land Use" section of this report).

㊼ Section 6.3; Page 6-3.
Omission: The statement does not explain the size of the harbor easement NTPC intends to obtain for the unloading facility. The easement if much larger than what is needed for 3 berths. NTPC should explain in the DEX the purpose of the larger easement and the cumulative impact involved. The larger easement is alluded to on page 7-8, section 7-9, 1st paragraph.

㊽ Sec. 6.3; Page 6-4; Col. 1, para. 5.
Deficiency: In section 6, page 4, 3rd paragraph under Tanker Unloading Facilities, is a statement saying there will be 511 tanker port calls if the Puget Sound Refineries were served by NTPC pipeline.

Table 8.4.1.2-1, Section 8, Page 22 indicates the combined port calls to the existing risk refinery facilities in the Puget Sound area plus tankers coming to Port Angeles will be 908 port calls per year. Eliminating the tankers serving the refineries and having the oil go by pipeline will mean 908 port calls at Port Angeles, not 511, as stated in Section 6. Which is correct? 511 or 908 tankers per year at Port Angeles?

㊾ Section 7.9.1; Page 7-4.
Question: Berthing facilities would pre-empt other industrial uses such as log storage. Also, it may force the Coast Guard to relocate. What alternative sites are there for log rafting, Coast Guard, etc.?

㊿ Section 7.10; Page 7-4; Para. 1.
What plans are made to keep the continuity of the prestigious Port Angeles Salmon Club Derby intact, without interuption of its 42 year history? Are these plans, if any, promises, or hard, concrete propositions for the derby's uninterrupted continuance at a site capable of launching the numerous boats in the accepted manner, and accomodating the parking of the cars, boat trailers, RVs, trucks and campers attenuant in the fashion accustomed in the preceeding years on land? Will the plans accomodate not only the launching of these boats, but the salt water mooring of some 200 small craft as is now currently practiced during the derby? If these plans are not formulated, and concrete, why not? It must be realized that the Port Angeles Salmon Club land lease on Ediz Hook also accomodates the following recreational fishing extravaganzas: 1. The internationally known American Legion kid's salmon derby (any child under 16 years old - boy or girl - fishes free from donated boats, gas, time, gear and food. 2. The illustrious, fun loving Elks derby. 3. The same category for the Eagles annual derby. 4. The Pen Ply salmon derby. 5. The handicapped people's salmon derby. 6. The long continuing Port Angeles Yacht Club fishing derby in early spring. 7. The smaller, local organizations salmon derbies to numerous to mention. Are these Port Angeles Salmon Club's well known facilities to be located on the Port Angeles harbor as have been accustomed and accepted by United States and international fraternity of salmon fishermen? If not, where does NTPC plan to locate such facilities, when, and how?

CONT

(51) Section 8.1; Page 8-3.
Deficiency/Question: It appears that minimum facilities would be displaced by locating the oil port at one of the alternate sites of Freshwater Bay or Low Point. The ES does not discuss advantages of placing the oil port in Port Angeles Harbor over the alternate sites. Why was Port Angeles Harbor selected over these sites? The reasons are not clear in the ES to the layman.

(52) Section 3.1.13; Page 3-46; Column 1, Paragraph 1.
Deficiency: The brief discussion of the impact on the USCG base is very inadequate. What are the consequences of displacing all or part of current Coast Guard operations on the spit? Recent 3/79 NTPC amendment to place berths further out on Hook is not discussed in the DES, nor was it of common knowledge prior to the public hearings.

(53) Section 3.1.13; Page 3-46; Column 1.
The DES makes the judgment that increased electric loads would not be significant during the construction phase. Please document this judgment.

M

LAND USE

① Clallam County has added specific language to its Comprehensive Plan banning major oil facilities, refineries and petrochemical plants anyplace in the county. This language is also proposed in its revised Comprehensive Plan. Table 1.5-1 should include Clallam County.

② Section 2.1.2.12; Pages 2-125, 3-40, 3-104, 8-43, (CFR, 1500.8).
Deficiency: Under land use and zoning the BLM states that it is EFSEC's responsibility to determine conformance or conflict of the pipeline with the County Shorelines Management Master Program. The above CFR requires the BLM to address this matter in the EIS.

③ Page 3-40; Column 2; Paragraph 3.
Deficiency: The statement is in conflict with city comprehensive plan to retain Ediz Hook public access and enlarge and improve recreational areas as they become available on Ediz Hook.

④ Page 3-54; Column 2; Paragraphs 1 and 2 and Page 3-55; Column 2.
Error: Paragraphs 1, 2 and 3 are erroneous and deficient. The Northern Tier project is incompatible with current land and water useage as it displaces existing industry and recreational facilities to relocation areas for 20 year project lifespan. Electrical power shortages compounded by Northern Tier project could result in worker layoffs and curtailment of current industrial expansion or new industries. Air quality degradation could have similar and added adverse impacts. These realities (not fears) have been spoken to on pages 3-51 and 3-46 of this DES), resulting in lowered profits for the mills and economic impacts for workers.

⑤ Deficiency: Both the City of Port Angeles and the County ban an oilport in their comprehensive plans based on public hearings and a public vote (City of Port Angeles).

⑥ Page 3-104.
Error: Draft Environmental Impact Statement says " . . . the Energy Facilities Site Evaluation Council has determined that pipeline system construction would be consistent with state and local planning and zoning." The tank farm is incompatible with the current Clallam County Comprehensive Paln as stated in the Description Section of the DES.

⑦ Page 1-10.
Deficiency: How much bunker fuel barge or tanker traffic will exist during maximum operation? If on-shore bunker fuel storage tanks are proposed the DES should be amended to include all appropriate information.

⑧ Page 1-28.
Deficiency: The photograph is not representative of what a typical plant with a 42-48 inch line will look like. This misrepresents the projects relative size and the amounts of land such a plant would require.

Page 1-42.
Deficiency: The photograph is not representative of the impacts covered by the placing of a corridor through a forest with crawler-dozers.

Page 1-43; Figure 1.4-11.
Deficiency: Artists concept shows a nice flat, cleared area where vehicles and activities have relatively little impact on any resources. This presents a misleading impression of pipeline laying for the reviewer of the document.

⑨ Section 2.1.1.12; Page 2-30.
Deficiency: The specific usage of land within 2000 feet of the tank farm should be described in detail. Table 2.1.1.12-2 reflects Clallam County land usage as of 1971. This information is 8 years old and the County has increased in population by over 25% in that period.

⑩ The last paragraph on the page lacks a discussion (required by 1500.8(a)(1) CFR) on how the proposed action conflicts with the specific terms of the County Shorelines Management Program. The wording on page 2-30 indicates only that the submarine line conflicts with regulations of the shoreline program.

⑪ Section 2.1.1.12; Page 2-31.
Deficiency: The map on page 2-31 is too vague. One could not get an accurate idea regarding land usage near NTPC facilities, especially the tank farm area. Much of the area shown as forest land is presently rural residential homesites especially in the Green Point vacinity.

⑫ Page 2-44.
Amenities: Ediz Hook is an important amenity for leisure time 300,000 days a year.

⑬ Section 2.1.1.12; Page 2-115.
Omission: The third paragraph of segment 1 omits the Dungeness River. The fourth paragraph states that this segment has a high scenic quality (A/B). The second paragraph on page 2-115 indicates that an A/B rating is a "moderate to high scenic quality." Therefore, if segment 1 is a "high quality" (moderate excluded) segment 1 should be rated A.

⑭ Section 2.1.2.12; Page 2-118.
Omission: The description of land uses along the pipeline route totally ignores an important catagory of usage-rural residential. The pipeline passes through considerable rural residential areas in Clallam County. Table 2.1.2.12-1, on page 2-118 also has the same omission.

⑮ Section 2.2.2.12; Page 2-162.
First paragraph omits Sequim. Also, this paragraph is so general that it is meaningless. More specificity is appropriate.

CONT

⑯ Page 3-11; column 1; paragraph 3.
The 140 acres only includes Phase I. Discussions should include Phase II.

⑰ Page 3-38.
The photograph with overlaid drawing of the cut in the bluff and the tank farm is very deceptive. Why are only 11 tanks shown when 25 may be built? Why are trees shown covering the site when 90% will be removed? Are the 285 foot diameter tanks rendered to scale?

Page 3-38 and 3-39.
Deficiency: Picture gives erroneous impact impression with only 11 out of 25 tanks in drawing pictured on page 38. If not familiar with agricultural/residential land use zoning and tremendous significant impact of 25 tanks each the size of a football field, viewer would not know scope and magnitude of impacts from total project. Picture looks as if tank farm will be hidden in forested area.

⑱ Page 3-39.
Error: States fewer than 20 residences are within 1,000 feet of proposed tank storage. Page 3-41 last paragraph in column 1 states fewer than a dozen residences would be within a distance of either 1500 or 1000 feet. Specific data should state residences now existing and current landowner plans for area encompassing an area much broader scope than this for impacted area.

⑲ Section introduction assumption #2 pertaining to the anticipated 20 year life cycle of the NTPC facility is not realistic. The assumption should be revised to reflect the history of usage of this type of facility including the pipeline. It is highly unlikely that the pipeline will be abandoned if it is in operable condition. Many other substances can be transported through a pipeline.

⑳ Page 3-40.
Deficiency: What would be specific size of forest buffer and location areas when total project complete?

㉑ Section 3.2.12; Page 3-103.
Omission: The section on agriculture should address how much agricultural land will be impacted by such ancillary improvements as maintenance and construction roads and power easements. Also the construction through agricultural land at the rate of one mile per day seems too unrealistic.

㉒ Section 3.2.13; Page 3-107.
Deficiency: Pipeline construction will necessitate construction of staging areas and pipe storage areas. The DES should identify the amount of land required for staging. These staging areas will generate noise, glare and dust nuisances for adjacent land owners and public road users. Slash piles will generate a fire hazard to adjacent woodlands.

㉓ Section 7.8.1; Page 7-3.
Deficiency: The wording of this section makes one wonder if the DES is reviving a two berth, 2 submarine line, 11 storage tank 709,000 BPD flow NTPC facility, or a 3 berth, 3 submarine line, 24 storage tank 1,283,000 BPD flow project. The DES should revise impacts of the latter if it is in NTPC plans to construct such a large facility in a reasonable future period.

㉔ Page 2-31; Map.
Deficiency: No designation for recreational use of Harbor: boat marina, civic peer, public beach, shrimping, boat launches, etc. Industrial and commercial uses are not synonymous. Land use plans nearly always make a clear distinction yet there is no distinction on this map. The entire southern harbor is not exclusively industrial.

㉕ Page 2-155.
Deficiency: Land use (storage facility site) — does not mention existing level of residential activity in vicinity: the number of plats approved for residential development.

㉖ Page 5-7.
Deficiency: Smog is not mentioned under Visual Resource.

㉗ Section 3.1.11; Visual Resources: Summary
Construction of the onshore storage facility at Green Point with clearcutting of 292 acres and construction of up to 23 tanks 285 feet in diameter and 56 feet high will be a major visual intrusion not moderate or low and will impact not just nearby residents but will be a visual intrusion dominating the scenery. It will be visible from the Straits of Juan de Fuca and from the Hurricane Ridge Road and perhaps from Highway 101.

Page 3-37; Column 1; Paragraph 1, and Column 2.
Deficiency: What economic impact would the highly visual degradation of Green Point have on current zoned residential/agricultural real estate values and future residential development in the Green Point area?

Deficiency: This section does not identify and address visual resource negative impacts as related to residential passive viewing as it effects view property, real estate values and sales. Also commercial real estate such as restaurants, motels and apartments.

Deficiency: Does not identify impacts related to current efforts of downtown merchants to update and improve visual atmosphere of downtown business community.

Deficiency: Does not identify impacts related to City Pier Project in progress and dependent upon retention of visual aesthetics of waterfront and Ediz Hook area.

Section 3.1.11; Page 3-37
Question: It is stated that the Green Point tank farm would be highly visible to residents and tourists. From how many locations would the farm be visible? From Dungeness Spit? From the Hurricane Ridge road? From the Straits? From Ediz Hook? From British Columbia?

㉘ Page 3-39; Column 2; Paragraph 7.
Error: Residential area and business area including Olympic Memorial Hospital could be impacted by noise, traffic and dust impacts. Residential and Business areas are not scattered either to the East or West but concentrated on harbor rim and harbor area, including restuarants and motels.

㉙ Section 4.12; Page 5-2.
Deficiency: The section on visibility should include an analysis of the tank farm separate from the unloading facility.

㉚ Page 3-40.
Error: The last sentence in the fifth paragraph is in error. The secondary effects of the tank farm are not explored. The presence of the tank farm may generate vigorous land speculation in the area. Tank farm workers will want to live near the tank farm in order to minimize energy costs of commuting. The air pollution from the farm will probably not significantly affect adjacent land up wind of the farm (south and west) and therefore additional development will take place in this area. Also, commercial uses will proliferate south of the area on the Old Olympic Highway and U. S. 101. The air pollution will devalue property down wind (east) from the farm. If it is severe enough it may cause displacement of residential and some commercial (tree nursery, Christmas tree farms, agricultural operations, etc.) land uses.

CONT

㉚ Note: the comments above also apply to the seventh paragraph on page 3-40.

㉛ Note: Land speculation is an adverse impact primarily because large amounts of land will likely be subdivided into lots which are manyfold more in number than the anticipated need to be generated by the NTPC facility. Therefore, the prematurely divided land which is not needed sits idle for tens of years not producing trees, fiber, food or residentially occupied space.

General comment: The DEIS does not adequately evaluate the impact of the facility on land values prior to and during construction. The anticipation of the project is likely to cause a rapid increase in the price of property. Speculation causes land to be purchased prematurely, often at very high prices and without regard to its suitability for development. Consequently, the price of adjacent land near the tank farm is forced up and many landowners may find themselves unable to pay the increased taxes on undeveloped property. Landowners living on the land may be forced to sell off the property due to the high taxes. However, this speculation near the project will trickle over to other property in the community forcing land costs up for everyone affecting especially low income and fixed income citizens.

㉜ Table 3.1.12-1; Page 3-40; Column 1.
Question: Has same deficiencies as related narrative and speaks only to two berths not total project. Addressing the Green Point area, the DES states project would use property which would have negligible impact in terms of undeveloped property in area. This is questionable based on use of residential/agricultural zoned land for industry with resultant significant impact to quality of life for current users and landowners and restraints to future development not only in initial construction phase but when impacted by total project. Also in relation to property devaluation from same, and problems related to electrical, water, services unavailability and increased costs.

㉝ Page 3-40; Paragraph 5.
Comment: Statement implies that industrial development would not set precedent for rezoning and increased industrialization. Ocean view homes will probably not desire to build adjacent to oil tanks and industry so the land will lose residential value. Secondary impacts should be evaluated and discussed.

㉞ Section 3.1.12; Page 3-39, 3-40 and 7-4.
The fifth paragraph, fourth line of page 3-40 is deficient and in error. Tank farm facilities and associated pipelines attract related energy facilities. This paragraph should identify the potential for related energy facilities to locate near a terminal facility such as the one proposed by NTPC. The same sentence cited above stated that no other industries would locate near the tank farm. This statement should be expanded to address the precedent setting effect of locating a high intensity use in an area which has never had such a use. The services and facilities necessary to serve the tank farm may attract other higher intensive industrial or commercial uses.

㉟ Page 3-58.
Statement: "Additional petroleum-based industry is unlikely."

Page 6-2.
Statement: "The location of Port Angeles is economically not conducive for the development of refineries or petrochemical plants."

This constituted the discussion of this issue and is grossly inadequate. In addition, it is probable both statements are ill founded. In fact, a Task Force member was perplexed by the conclusory nature of these statements and called the Portland Office and spoke to the BLM team member who was responsible for this judgment. He could not cite a specific reference upon which this judgment was based. It was the product of the EIS team's personal judgment.

By contrast, another Federal EIS on another deepwater oil port facility--the final EIS on the LOOP Deepwater Port License Application found that EIS devoted five separate sections plus 62 pages in the Appendix to the issue of secondary development. These were some of the findings:

> Historically, refining capacity has tended to locate where crude is. A correlation analysis between refining capacity and crude oil production for Louisiana revealed that the co-efficient of correlation was .89." (or 89%)
>
> As domestic oil production in PAD III declines, new refinery growth will have to depend on foreign crude and will tend to be built where foreign crude oils can be most readily obtained, i.e. in the coastal region. Refineries will also tend to locate on the coast to allow ready access to pipeline networks and tanker transportation systems which deliver products to markets outside PAD III. Another minor reason for locating on the coast is that a refinery uses a part of its crude oil supply (often 3-5%) as fuel to run the refinery. Moving crude a long way thus increases the cost of refinery fuel, and given the opportunity a refiner will minimize such costs. (C-96)

We consider this an important issue. The U.S. Department of Transportation seemed to consider this an important issue in the development of the EIS on the LOOP deepwater port facility. Yet, BLM has not responded to public input on this matter. Clallam County is on record as early as June 2, 1977, (nearly 2 years ago) requesting that this be given due consideration by the EIS team. Clallam County reiterated that concern again on January 10, 1978. It was verbally reiterated at three meetings of the BLM Coordinating Committee by the then Chairman of the Board of Clallam County Commissioners.

This is a proper concern of local government and one that NEPA requires a lead agency to fully examine. A publication by the United States Coast Guard entitled: Guide to Preparation of Environmental Analysis for Deepwater Ports acknowledges this obligation as well. We would like to quote it:

> Since the construction of a deepwater port is likely to entail many second order and higher order costs and benefits (such as the effect of terminal associated refining and petrochemical activity, and the indirect effects of this activity), and since they may be very large, the applicant should discuss them thoroughly. (6-5)

The LOOP EIS further states:

> The development pressures stemming from petroleum-related industrial growth. . . will create a need for major new public expenditures. For example, about $3 billion will be required for new schools, utilities, street and roads and other public facilities by 2000-2010. LOOP-related activities will contribute to these needs.
>
> This situation has the potential for adversely affecting the operation of local governments in the Corridor for significant periods over the next 35 years. . . A number of local governments will be hard pressed to fund new facilities and services during these times. (5-11)

CONT

㉟ Industry sources have estimated that U.S. consumer product needs will require 17 new refineries before the year 1990. A recent article in the Seattle Post Intelligencer (March 12, 1979) reaffirmed similar estimates. It is the apparent consensus of government, congressional and oil industry energy experts that, contrary to popular belief, the current petroleum shortage is not due to the Iranian cutoff. Rather, it is the lack of U. S. refinery capacity--not the loss of Iranian oil--which is responsible for the shortfall.

Where will these new refineries locate? They have historically located where the crude oil is, not where the market is. A good example of this is, again, the Gulf Coast. Approximately 53% of all products refined along the Gulf Coast is shipped out of that region. (C-84) The two largest product pipeline systems in the United States originate in the Gulf region. One extends from Baton Rouge, Louisiana to the Washington D. C. area and the other extends from Texas to the New York/New Jersey area. Transit time of a product barrel is approximately 12 days from Houston to New York. (C-84) By comparison, then, the Olympic Peninsula is by no means an unrealistic location for a refinery with access to the entire West Coast product market via both waterborne vessel or by pipeline connection with the Olympic Product Pipeline System.

This is not a condition endemic to the Gulf Coast. A similar scenario is occurring in the State of Alaska. During 1977-1978, eleven different proposals were submitted to the Alaska Oil and Gas Royalty Board for new refineries. (OGJ 9-26-77) A refinery will be sited at Valdez. The same thing could occur at Port Angeles. If Port Angeles becomes the site of the country's largest onshore crude oil terminal, as is proposed for this project, then Port Angeles is an equally likely candidate for refinery development.

A key element of the U.S. Corps of Army Engineers West Coast Deepwater Port study was the likelihood of refineries locating in the vicinity of a new deepwater port. In fact, each port site the Corps considered, including Port Angeles, was evaluated in terms of the feasibility of that Port site for refinery development. Port Angeles was a feasible location.

According to the U.S. DOE's recently released petroleum supply alternatives for the northern tier and inland states: the State of Washington can expect an increase in refinery output of over 200,000 b/d by the year 2000. That is the equivalent of two new refineries.

On January 22 of this year, it was announced that American Petrofining plans to locate a 250,000 b/d refinery in Western Washington. The Port Angeles area is a candidate site.

In summary the BLM has not fulfilled its responsibilities under NEPA to fully examine secondary development as a logical consequence of a major crude oil terminal at Port Angeles.

Also see: Offshore Petroleum Transportation System for Washington State, Feasability Study OCW page IV 157 last paragraph and page 158 first paragraph.

㊱ Page 1-44.
Deficiency: More information should be given on the coordination of pipeline construction activities with other utilities to assure that an existing utility is not inadvertantly severed. Also, the DES should identify the potential for severing and existing utility by pipeline construction.

㊲ Section 3.2.12; Page 3-105 and 3-106.
These sections do not adequately detail the land use impacts of the pipeline. The pipeline corridor often attracts undesirable recreation activity (ex., promiscuous shooting, vandalism, trespass, sabotoge, poisonous weeds in Western Washington). Maintenance roads generate subdivision activity. The pipeline splits wooded and agricultural ownerships creating land management problems. Some ownerships are intersected in a fashion which creates small slivers of land which cannot be managed for any use. Uncontroled recreation uses create problems such as erosion, vandalism, fire protection, etc.

Section 7.9.1; Page 7-4.
Deficiency: If the berthing facility will intrude on Coast Guard Station, the DES should be more specific about the impacts and the specific NTPC facility that will intrude. This and related concerns are addressed in the "Harbor Management" section of this report.

The DES does not adequately describe the impacts of the pipeline construction on the movement of groundwater. The movement of groundwater or alteration of its movement needs to be carefully analyzed prior to approval and construction of the project. This and related concerns are further addressed in the "Water Quality" section of this report.

㊳ Page 1-16.
Deficiency: What is the sabotoge potential on the tank farm given the extent of the described security system?

㊴ Deficiency: The influx of construction workers and facility operators will generate demands for additional housing which in turn will generate an administration cost to County and City governments. This cost arises when City and County planning staffs are overwhelmed with processing project proposals submitted by developers. Both public agencies may need to employ additional personnel in order to process the projects in sufficient time to meet the new housing demand as well as processing other projects which are attracted by this new growth. The statement should specify how much timber land in each county of Western Washington will be lost due to the construction of the project. Include amount of board feet lost over an 80 year harvest cycle.

㊵ Page 3-39; Column 1; Number 3.
Error: It is an error to state current adjoining land uses are incompatible with the project. Northern Tier's total project is incompatible with current land uses, and necessitates relocation, curtailment and restriction on future industrial, residential, commercial, and recreational land uses.

㊶ Page 3-39; Column 1, Abandonment under 1.
Question: No basis for assumption project facilities will be dismantled. Not specifically stated in project description. What measures will be taken to protect city and county from unknown impact at any stage of project termination which could result from conversion of project site and components into further industrial usage.

㊷ Page 3-39; Column 1.
Deficiency: Project does not speak to total project impacts relating to construction and operation with ongoing construction and increased operational risks and impacts within five years from initial construction phase.

㊸ Page 3-39; Paragraph 6 above column 2.
Deficiency: Does not consider current expansion plans for industrial, recreational and Coast Guard uses and impacts on same. Also impacts to other land users such as Merrill and Ring during construction and especially with harbor entrance access restricted for months. (Volume 3, part 2, Site Certification Northern Tier Pipeline, page 2.10-3)

CONT

㊹ Page 8-29.
Question: Where would onshore storage be located at Freshwater Bay? How much acreage would be required? Page 8-31 notes 140 acres, Page 8-37 notes 294 acres, Page 8-42 notes 150 acres clearcut and 150 acres fenced (total 300 acres).

㊺ Section 2.2.1.2; Page 2-154.
Question: What is the basis of the population projection set forth on the second paragraph of this section.

Section 2.2.2.15; Page 2-164.
Error: The population projections for Clallam County on Table 2.2.2.15-1 are already proven to be conservative estimates as verified by population estimates from the State to April of 1978. For example, the 1980 estimate is 44,000. The County reached that figure in early 1978.

㊻ Section 3.1.12; Page 3-52.
Question: The mobile homes projected to be used by transient construction workers will probably be located in the unincorporated area because of the cheaper land and lack of zoning as compared to the City of Port Angeles. Also, construction camps will be located in the unincorporated area because such camps would not be allowed by city zoning. Also, the escalation of rents due to construction activity will undoubtedly displace low and marginal income families to areas which allow for cheaper housing which may be in the unincorporated areas near County roads. Rural land owners would rent their property at cheaper rates than in the City and thereby attract low income mobile home placements.

㊼ Page 3-54; Column 1.
Deficiency: What effect would housing rental increases of between 20 to 25% have on community service demands from Washington State Department of Social and Health Services during the 22 month minimum construction period and returning again in the other construction periods? Relating to low income and fixed income people?

㊽ Section 6.3; Page 6-3.
Omission: Information should be given regarding the compatibility of the tank farm location to the intent and purpose of the Magnuson Amendment.

㊾ ection 3.1; Page 3-54 and 7-4.
Error: Last two paragraphs on the page identify the views of some other persons other than the author/applicant. This type of wording is interspersed throughout the statement. This type of wording does not belong in the statement unless the applicant/author agrees that this is a impact(s) worth exploring. In other words there should be no reference to what other persons think unless the person is an objective expert in the field and worth quoting.

㊿ Section 4.9: Page 4-4; Paragraph 2.
Omission: Reportedly, in presentation of biological data the U. S. Fish and Wildlife Service has indicated that Green Point is an unacceptable site for a storage tank facility because of the nature and severity of the anticipated losses that could not be mitigated.

N

## LAW ENFORCEMENT

Law enforcement is a vital concern and if an oilport is located in Port Angeles, it will undoubtably require an increase in police services and other areas of the criminal justice system. There is great difficulty in assessing our needs because it is difficult to determine how fast a build-up of personnel related to all aspects of the oilport project will occur and there is no way of determining the composition of the work force. The questions that need to be answered are numerous when looking at the oilport issue and its effects on police service. The impact questions will be listed under two headings, direct impacts and secondary impacts.

① DIRECT IMPACTS: It is difficult at best to estimate the number of people that will move to Port Angeles and Clallam County as a result of the initial construction period. Are we talking about 2,000 people, a lot more, or much less? What kind of people will be moving to the area? Will they be more involved in criminal activity than someone that is an established resident, i.e. fights, vandalism and other alcohol related incidents? What will be the increase of vehicular accidents due to increased traffic from construction vehicles, workers vehicles, and their families vehicles? How much will tourist traffic increase? How much more routine police traffic patrol will be needed to handle the above stated traffic problems? How much impact will there be on the police department's parking enforcement program in the downtown area?
With the influx of a large number of transient workers will prostitution become a problem? Will bad checks become a major problem? Will family fights become a problem? How much other, not mentioned, criminal activity will crop up? Another thing that comes with rather large numbers of people are their pets. How much impact will there be on animal control? How much security type patrol will be needed in the construction area?

After the manpower figure is developed what will be the cost of equipment including vehicles needed to supply not only the police officer on the street, but the investigators needed for follow up work and the clerks needed to handle the paperwork generated?

② With only an 18 month job in mind, what quality of recruit police officers would we get? With the need, under state law, to send all newly hired officers to basic law enforcement school, within 15 months of their date of hire, would this mean we would have to hire more officers than actually needed because of the loss of officers to basic training?

③ SECONDARY IMPACTS: After the initial construction period ends, and the number of employees hired by the oilport construction firm drops off, how many of the people will stay in the area and go on our unemployed roles? Would these persons also become a law enforcement problem? After the pier or docking facilities are completed, what kind of problems will the ships crews be? What kind of manpower needs would develop from the responsibilities of guarding the pier from vandalism and possible sabotage? Would there be a need for a police harbor patrol boat to supplement the Coast Guard's responsiblity?

④ One of the major secondary impacts would be determining what to do with the extra police officers and other police personnel after the initial construction period is over. They were needed for that approximate 18 months, but may not be later on.

CONT

Beyond question an oilport industry locating in Port Angeles and Clallam County will increase the demand for police services. Added responsibilities of protecting people and property will require an increase in personnel to cope with the demand. The following areas of concern should be addressed in the DES, regarding impacts on the Port Angeles Police Department.

During the Construction Period:

⑤ 1. Traffic increase in volume to and from the Ediz Hook site will be significant. All materials and construction workers will be in direct competition and conlfict with existing industry west of the downtown area to the construction site unless moved via water to air. Bottlenecks due to physical layout of the streets (such as the area through the Crown Zellerbach mill) as well as those created by shift changes at Crown Z or M & R Timber Company mill are seen as major accident causing factors that will require the constant attention of law enforcement officers.

⑥ 2. The influx of construction workers will increase the volume of activity in areas of housing, in restaurants and recreation facilities, and in drinking establishments. All of these factors will mean an increase in the volume of incidents such as fights, vandalism, assault, disorderly conduct, family beefs, both major and minor crime.

⑦ 3. Parking will be effected by the influx of construction workers particularly where it conflicts with the fishermen parking on Ediz Hook. Parking has been a problem for several years on Ediz Hook due only to the volume of fishermen without the confusion of a large construction project.

⑧ 4. The stockpiling of construction material and equipment will be a major concern during construction due to its being a potential target for sabotage, vandalism and theft. A major construction company has been active on Ediz Hook in recent years on a project very favorable to the vast majority of the populace. Vandalism to their equipment was frequent and costly until fairly expensive and extensive steps were taken. We can visualize any oilport construction as being many times more significant due to the project being as unpopular as it is.

During the Operation Period:

The people who will man and operate the oilport physical plant, related tug and service vessels, security people, maintenance people and others who will be permanently located in Port Angeles and Clallam County will increase our population. A fair percentage of the tanker crews who will be traveling between Valdez, Alaska and Port Angeles as a regular routine run will surely select Port Angeles as their home port.

⑨ Somewhere we have been supplied a figure of 30 to 45 tankers per month discharging oil in Port Angeles. Conservatively this number of ships will have between 500 and 700 crewmen who would likely locate in our community. If each crewman has a family of three we are seeing between 1500 and 2100 people added to our responsibilities. This number of people would generate a consdierable number of new housing units, new businesses, new utilities and services, all of which become a concern of law enforcement in the protection of life, limb, and property.

Our ratio of law enforcment officers to population at present is considerably below the state and national averages. Our support service employee numbers are about average considering the broad areas of responsibility in addition to the regular and usual operations of a police service of our size. The people of our community deserve police protection equal the average level in our state.

⑩ In the event of any type of disaster related to an oilport be it an extensive oil spill, fire, or explosion, there would be added responsibilities of the protection of life and property for law enforcement. Depending on the type of emergency created, there would always be traffic control problems for emergency vehicles and crews to a greater or lesser degree. Our hope is that there would be built-in safeguards to prevent any type of emergency, but are realistic enough to realize that nothing is 100% foolproof and the possibility will exist.

⑪ Any updating requiring an increase in personnel will place a financial burden on the community.

Our budget will have to be increased to meet the demand roughly as follows based on 1979 figures:

General Needs:

| | | |
|---|---|---|
| 5 Police patrolmen | Salary | $82,320.00 |
| | Benefits | 12,105.00 |
| | Equipment | 2,750.00 |
| | Training | 25,000.00 |
| 4 Vehicles | | 32,000.000 |
| | Vehicle equip. (Radios,etc.) | 7,500.00 |
| | Vehicle rent/ Maintenance | 31,920.00 |
| 2 Clerks/Dispatchers | | 20,016.00 |
| | Benefits | 6,652.00 |
| | Training | 920.00 |
| | | $221,183.00 |

Determining the need of a harbor patrol boat at this point in time with the information available is an uncertain shot in the dark. The need for vessel traffic control, enforcement of boat safety laws, search and rescue, and related water activity is traditionally in the jurisdiction of the U.S. Coast Guard with few minor exceptions. Should the U.S. Coast Guard Air Station and the locally based vessels be removed from the area then there will be a positive need for an adequately manned vessel. The vessel will have to be equipped with all necessary search and rescue, as well as, law enforcement materials and manned 24 hours per day, 365 days per year.

A conservative estimate of cost for such a vessel with related equipment would be in the neighborhood of $250,000.00 and be much like the vessels owned and operated by the Puget Sound Pilot Association.

126
CONT

⑪ A minimal crew would be three officers to operate the vessel and its equipment. A three man crew would require 15 officers be added to a harbor patrol division.

At 1979 Salary Level:

| | | |
|---|---|---|
| 15 Officers | | $246,960.00 |
| | Benefits | 36,315.00 |
| | Equipment | 8,250.00 |
| | Training | 75,000.00 |
| | Total budget increase with vessel-- | $616,525.00 |

Jail costs are an unknown factor at the present as hopefully the new Clallam County Jail will be in operation in 1980 with all city prisoners housed there via contract. The contract likely will call for about $20.00 per day per prisoner.

Not addressed thus far in this update is the present physical facility which is small and cramped to capacity. Added personnel will require remodeling and expanding the present police building at a considerable cost.

We have not addressed other budget factors relative to added salary for supervisors and administrative services, moorage fees for harbor patrol, fuel and maintenance for the harbor patrol, etc.

The ultimate result of this update indicates that the police department would conceivably be doubled in numbers, expanded physically, add a harbor division and more than double the annual budget. There is no reasonable way that the present people of the community should shoulder the burden for the entire costs and still lose the tranquility and lifestyle enjoyed currently.

Total costs would exceed a million dollars should a harbor division be needed and around a half a million without.

The following areas of concern should be addressed in the Environmental Statement, regarding impacts upon the Clallam County Sheriff's Department.

Considerations during construction phase:

a. Population increase (The projected population data utilized herein has been generated by the BLM. Local governments have established that these figures may be conservative by one-half).

| | | |
|---|---|---|
| 1. Increase: | Expected monthly average - Northern Tier | 573 |
| 2. Increase: | Service and supporting industries | 50 |
| | | 623 |

Result: Increase in population will result in an increase in incident rate requiring the response of law enforcement officers.

b. Traffic increase

1. Construction traffic - Construction traffic affecting the Clallam County Sheriff's Office (CCSO) is expected to be primarily confined to the eastern area of Clallam County with most of the activity on the feeder roads leading to the Green Point construction site.
2. Personal vehicles - Increase in traffic caused by the increase in privately owned vehicles is expected to be primarily confined to the Port Angeles area with peak increases in traffic during shift changes at construction sites.
3. Ship and barge traffic - The increase in ship and barge traffic related to construction is not expected to have a significant effect on the CCSO work load.

Result: Increase in construction and privately owned vehicle traffic will result in an increase in the accident rate, requiring the response of Law Enforcement officers and emergency vehicles.

c. Vandalism and sabotage

1. Construction equipment and vehicles
Construction equipment and vehicles often present an easy target for vandals and sabotage.
2. Construction site
Construction sites at both Green Point and Ediz Hook will offer targets for vandalism and sabotage activities.
3. Construction supplies
Construction supplies will also offer a target for vandalism and sabotage.

Result: Although Northern Tier will provide security personnel during the construction phase, there will be an increase in vandalism requiring the response of Law Enforcement officers.

Sabotage is not expected. However, should it occur, there will be a significant increase in related law enforcement requirements.

d. Thefts

Construction equipment, construction vehicles and construction sites offer relatively accessible targets for theft.

Result: Although Northern Tier is committed to providing security personnel during the construction phase and the operational phase, we can expect an increase in the theft rate in Clallam County.

CONT

Considerations during operational phase:

a. Population increase (Conservative estimate):

| | | |
|---|---|---|
| 1. | Increase due to NT employees and families | 150 |
| 2. | Increase due to service related industries | 100 |
| 3. | Tanker crews<br>Increase caused by relocation of US tanker crew families to Port Angeles | 100 |
| 4. | Tanker crews shore leave<br>Average daily influx | 35 |
| | | 385 |

Result: Crime incident rate will increase.

c. Sabotage and vandalism

Although NT will provide site security and pipeline patrol, we can expect an increase in the vandalism rate caused by the relatively accessible targets and the ill feeling toward NT by a segment of the local population. Internationally motivated sabotage is not expected.

Result: Vandalism rate will increase.

d. Explosive potential

The explosive potential of crude oil is relatively low. Gasses accumulating near the surface of crude oil produce the greatest hazard. Floating storage tank covers assist in decreasing the danger.

Result: Risk of explosion is always present.

e. Oil spills

Although the probability of a major oil spill occurring within the Port Angeles harbor or near Port Angeles is relatively small, the CCSO must take this possibility into consideration. Should a major spill occur the work load of the CCSO will increase dramatically.

Result: Covered in other statements.

f. Ill feelings

Northern Tier's Oil Port facility at Port Angeles will generate a significant amount of ill feelings toward NT and their employees by a segment of the local population. This ill feeling can be expected to result in an increase in incidents, i.e. assaults, all requiring the response of Law Enforcement officers.

Result: Increase in incidents requiring the response of law enforcement officers.

⑫ Resume: The largest impact on the CCSO caused by Northern Tier's Oil Port facility will be felt in the eastern area of the county. The increase in the accident and traffic rate will be significant and these increases will require additional man power in the CCSO. The addition of two field deputies should prove adequate to cope with the expected increase in the CCSO work load. Two additional field deputies should commence their employment at the CCSO when the construction phase of the Oil Port facilities commences. Additional requirements can be met by hiring reserve officers on a temporary basis.

Cost estimate:

| | |
|---|---|
| Extra help (reserve deputies) during construction phase | $15,000 |
| Two field deputies (includes prorated vehicle costs, gas, oil, uniforms, wages, benefits, etc.) | 55,000 |
| Additional administrative costs | 5,000 |
| Additional confinement/detention facility costs | 5,000 |
| | 80,000 |

Estimate of yearly cost during construction period. $80,000.

Estimate of yearly cost during operational period. $70,000.
Note: Additional extra help decreased to $5,000

The office facilities available to the East End detachment of the Sheriff's office should be increased.

⑬ The Environmental Impact Statement is very deficient in its discussion of law enforcement related impacts. This is most apparent in the lack of consideration of the need for additional support needed by the Sequim Police Department, particularly in light of the recent announcement that the pipeline route will become submarine from the vicinity of Port Williams.

How large will the population increase be as a result of the NTPC amending its application to utilize the "cross-Sound" pipeline route?

⑭ Will the pipeline construction staging areas, formerly planned for the Discovery Bay area, now be located near Sequim? At exactly what location will the staging area be placed?

How long will the staging area be in operation?

To meet reasonable standards for law enforcement the Sequim Police Department will need additional personnel and equipment. Normal patrols will have to be increased. Traffic control personnel and equipment will need to be increased considerably. The Sequim Police Department office and jail facilities may have to be expanded.

⑮ p. 5-21.
Omission: Table 5.2.15-1 Impact of operation -- does not mention the problems of security sabotage, fire evacuation, explosion recovery, and vandalism.

The Environmental Statement should include planning to cover security of all facilities during both construction and operation.

The Trans-Alaska Pipeline and other pipeline project experiences should justify the inclusion of sabotage-prevention plans.

CONT

⑯ Planning to minimize vandalism should be addressed.

p. 3-53.
Deficiency: Does not address economic impact on community related to taxpayer dollars needed for all Police Department operation costs during construction. Does not address lack of trained personnel to protect community.

Deficiency: Does not address types of disasters and impacts on police related thereto which could be induced by Northern Tier's operation.

Deficiency: No specific abandonment procedure is identified. Imperative this be specifically stated as it could occur any time prior to 20 year project life expectancy.

Comment: The DES should have discussed the incremental growth which the project (primarily in its construction phase) will cause in the entire criminal justice system. For example, will there be a need for additional judges, probation officers, clerks, Deputy Prosecuting Attorneys, secretaries, etc.?

O

MEDICAL

① Table 2.1.2.15-1.
Deficiency: Social and Economic Conditions: It is misleading to simply list Clallam County as having two hospitals since one is over 60 miles away, to the west, in Forks (See table 2.1.2.15-1)

Medical services: It should be noted that the hospital site almost at the entrance to the harbor about 8000 feet from the tanker berth and is therefore vulnerable to both fire and explosion. If it is incapacitated the next nearest hospital is at Port Townsend 46 miles away over narrow winding roads. The community has very limited capacity to transport injured people. The number of ambulances should be given. A mitigating measure to be considered in light of expected explosion in the harbor every 4.6 years would be to relocate the hospital in a safer place or to make it explosion and fireproof with added noise barriers and air pollution equipment to protect it from these adverse effects as well.

② Sec. 3.1.2-1.
Omission: Emissions from construction 3.1.2-1: Should be given for the full project. Noise levels and hours should be given with reference to proximity of the hospital and residences. Although the state exempts construction noise from most of its standards, these standards should be cited to give evaluation comparability levels. The duration of emissions and maximum concentrations should be given from the the project's air pollutants at the project boundary and at Olympic Memorial Hospital, and at the nearest residence to the tank farm site. For particulates a 24 hour average would be adequate, but for oxidants, sulfur oxides and nitrogen oxides five minute and one hour maximums should be stated and for hydrocarbons a one hour; and a three hour average should be included. There are hydrocarbon sensitive persons and a one hour concentration would be able to affect their brain function. If air pollution values are to be excessive at one or more residences a mitigating measure might be re-location during the period of high emissions. With the fire and explosion hazard, relocation of the hospital would be one mitigating measure; or, alternatively, provision of fire and explosion proofing of the building. The hospital might also require air conditioning to control air pollution to hospital-safe standards.

Sec. 1.4.
Deficiency: How many pumping stations will be needed for 1.283 million bpd? Do they run through the night? Describe noise shielding to be used and maximum noise at the property fence for each station both for the project and for current background levels. How many residences will be affected by being able to hear each of the pumping stations?

Very inadequate mitigation discussion related to noise impacts. EPA permit process should require much more mitigation, in the case BLM does not adequately provide for this.

③ The immediate impacts of construction upon Port Angeles and the harobr are of concern. The economic well-being of Port Angeles may be affected if the oil port has a detrimental effect on the mills and tourist industry. Possibly the biggest concern is the long-range sociological change that will occur in Port Angeles as a result of this project. The DES fails to discuss the present and foreseeable levels of mental distress suffered by some residents of the Clallam County area as a result of the project.

Omission: The U. S. Public Health Services and the State of Washington Department of Social and Health Services should have provided evaluations of many of the technical aspects and impacts of the NTPC proposal for inclusion in the DES. Many of the aspects of the proposal are beyond the scope of local government capabilities to analyze.

④ Sec. 1.18.
Error: (1.18-5) Top paragraph -- incorrect to lump ophthalmologists and optometrists together. Optometrist is not a medical doctor and is not licensed to treat eye injuries or most diseases. He measures vision.

Sec. 1.18.
Deficiency: The DES does not address the explosion or major fire concept adequately. No plan or method of warning is included. Section 2-44 constitutes the major emergency situation with lack of manpower, equipment and time -- all three elements of a disaster. The second major problem would be the evacuation of areas from the lower section of the city and the areas along the bluff. Any explosion in the harbor will produce a shock wave which would have no resistance over water with the full effect along the shoreline into the central area. The Coast Guard Report, 16732/71895 notes that minor damage extends 3 to 6 miles from the explosion with the shock wave traveling overland. The 200 foot height of the bluff would have very little deterioration power of the wave and might reinforce it due to energy uplift from the surface front. A shock wave from Ediz Hook would extend into the atmosphere as far as it would extend in all directions from the center of the explosion. Therefore, a shock wave reaching the shoreline would be high enough to damage the structures on the bluff including the hospital and possible cause the chlorine at ITT-Rayonier to rupture.

CONT

⑤ DES should discuss project-related injury levels, based upon previous projects like the Trans-Alaska Pipeline System. This type of analysis will allow better planning by the medical facility administrators.

⑥ Page 3-53.
Deficiency: Does not speak to emergency treatment load for hospital nor to major accident or disaster related to construction phase.

Deficiency: Under police needs on page 3-57 it is stated traffic accidents will increase, as well as drunkenness, fights, and family disputes. Quantification of such accident rate increases should be offered by the BLM.

⑦ Sect. 3.1.15; P. 3-54.
Deficiency: This section briefly mentions higher levels of demands during construction for grocery stores, public offices, restaurants and public establishments. Public and private establishments would be crowded. Yet under medical services the DES states no significant demands would occur. This discussion of impact should be expanded, and mitigating measures addressed.

⑧ Sect. 3.1.12; P. 3-41.
Question: What quantity of OIL SPILL would be required to impact boundaries outside storage facility?

Sect. 3.1.12. P. 3-41.
Comment: Col. 2, para. 1. "Assumption" is not proper procedure description for abandonment procedures.

Sect. 3.1.12; P. 3-41.
Deficiency: Para. 1, page 3-39 states "Once a land use is displaced, it is unlikely that it will return to its original use". This is in conflict with statement in this paragraph 2, page 3-41.

⑨ Question: What redress will be made to occupants of residences near Green Point for noise disturbance in excess of Washington State noise standards during nighttime construction activities? This will last 8 to 12 months. Do any of the impacted residents have health problems such as heart disease, nervous or mental illness or high blood pressure which might be aggravated by the noise? What measures are planned to monitor this so suitable compensation for health effects can be made if warranted? What basic monitoring for these same health parameters will be made to either Green Point area or for residents impacted near the harbor area? Will hospitalized persons be monitored for compounding illnesses resulting from the NTPC project?

Question: Noise levels especially from harbor construction and operation of pumps at the port are of particular concern because first of the proximity to Olympic Memorial Hospital and secondly due to the clustering of residences around the harbor. The nearby hills tend to contain sound. What is the regulation for permissible noise level at the hospital boundary? How will the proposal conform to this? The hospital will be less than 8,000 ft. from the tanker berthing area.

⑩ Table 2.1.1.3-2, 2.1.1.3-4.
Question: The length of time over which sound was measured should be stated in the tables so that one can judge persistence of sounds (See table 3.1.1.3-2 and 2.1.1.3-4). Why was a 10 db correction factor added to the night time sound level? If this were not done what would the measurement values have been for 24 hour averages? What will noise levels be with the project in full operation for comparision with these same tables?

⑪ Deficiency: The BLM study of the Northern Tier Pipeline Company proposal appears to be inadequate in several areas with respect to fire and explosion data.

1. Worst possible case analysis:
   a. It is assumed that a 300,000 DWT vessel explodes. Severe structural damage is said to occur only within a radius of 1650 feet and moderate structural damage to 2250 feet. Yet in the S.S. Sansinena explosion of December 17, 1985, (see Coast Guard report number 16732/71895) involving a much smaller (70,000 DWT) vessel, heavy damage is described up to 1 1/2 miles from the site and scattered damage (on approximately equivalent term to BLM's moderate structural damage) more than 3 miles away. This Coast Guard study is referenced by BLM but there is no discussion of this discrepant data.
   b. Further, in this same study, the Coast Guard places the dollar damage at $21.6 million. There is no discussion by BLM of who bears financial responsibility and what dollar figure might be expected.
   c. With respect to "preventive measures and contingency plans", BLM mentions a "fire fighting escort vessel" but provides no information as to its size and pumping capacity. There is no discussion of how many fire boats are necessary. There is no discussion of the number of fire trucks required, who will provide these trucks, or where they should be stationed. In the C.G. study referred to above, the following were used to fight the effects of a 70,000 DWT vessel fire (remembering that we are dealing with vessels of 300,000 DWT or more):
      (1) 5 fire boats.
      (2) 7 fire engines.
      (3) 9 ambulances.
      (4) 2 helicopters.
      (5) 240 uniformed fire fighting personnel.
   d. With respect to injuries and medical care required, no discussion is provided. In the above C.G. report 22 crew members were injured, 8 crew members were killed, 1 termial security guard was killed, and 36 "innocent bystanders" were injured. The only hospital capable of providing emergency care of any scope on the North Olympic Peninsula is Olympic Memorial Hospital located approximately 7800 feet from a berthing site. This is well withing the range of structural damage from an explosion. Similarily, the C.G. bases is located next to the berthing sites. What would be the effect of an explosion on the ability of the C.G. to helicopter patients to Seattle, particularly if the local hospital were unable to provide the necessary support either by virtue of overcrowding, structural damage, or excessive quantities of smoke?

126 CONT

11

2. Subjects not considered:
   a. As mentioned above, the Olympic Memorial Hospital of Port Angeles is the ONLY medical facility on the North Olympic Peninsula. The hospital is located approximately 7800 feet from a berthing site. There is no discussion of possible impacts on this hospital, either from a catastrophic explosion or even effects of overcrowding during construction phase. Further, it is apparently assumed that an explosion can only occur at a berthing site. This assumption appears invalid; what would be the effect on the Olympic Memorial Hospital if the explosion occured 5200 feet or less away? Could smoke from such a fire render the hospital nonfunctional? Is there a major facility in this country located this close to a major oilport? Should our hospital and therefore our community be put at such risk?
   b. With respect to other buildings, homes, fuel storage areas, etc. located on our harbor, there is no discussion as to possible impacts secondary to a major explosion. Could a vessel on fire drift toward shore and endanger any of the above?
   c. There is no discussion of the adequacy of the road on Ediz Hook to both provide necessary support services in the event of an explosion and to transport victims away from the scene. Could this road be seriously damaged by such an explosion and rendered non-functional?

   d. The factors which can intensify a blast effect should be discussed thoroughly. This is particularly necessary regarding relevant characteristics of local topography. One way the blast effects are intensified is through temperature inversions. Another way is by a following wind. Both of these weather traits would be frequent occurrences in the Port Angeles area. Structures on the mountain slope facing the proposed tanker port would increase the chances for damage from intensified blast waves.

   To avoid litigation from routine demolition activities at its depots the Department of Army on contract DA-04-495-ORD907 in 1957 had the Explosives Research Group, University of Utah, under Dr. M. A. Cook, develop guidelines for detonating chemical explosives without damage to private property. Table A, page 16 of their report, "Measurements of Air and Ground Shock Disturbances arising from Demolition Activities at Umatilla Ordinance Depot" shows window damage at the extreme distance of 4,000 feet for an explosive charge of 1,000 pounds. In Table C on page 17 of the same document an instance where windows were broken at 10,000 feet by a 2,000 pound charge. The report confirms that window glass failure occurs before any other structural failure.

   It is recommended that air shock intensity measurements be made under varying meteorological conditions at Port Angeles before any decision is reached to place explosive cargoes in the harbor. There is an Emergency Explosives Anchorage at Freshwater Bay. Determine procedures used to locate such an anchorage.

It is obvious that the BLM-DES analysis of this important area has been superficial. An in-depth analysis of fire and explosion risks is essential.

12 Deficiency: Most campsites in Clallam County that are not on city sewer, have on-site disposal systems (i.e. septic tank and drainfields) that were designed for seasonal use during the summer. Full-time use of these systems year round by construction workers will lead to drainfield failure and surfacing sewage problems. This is a severe public health hazard.

13 Omission: Impacts of undetected spills (up to 3,540 barrels per day) on homes using ground or surface water for drinking water are not given. Once the ground water aquifer is contaminated with oil what will homes using that aquifer do for water? Main areas to be concerned with are high water tables and permiable soil, where the pipeline would be buried right in the water table. What are the impacts of shallow wells and springs serving homes in such areas?

Deficiency: The BLM should more thoroughly study the impact of the pipeline on ground water quality (degradation). NOTE: Further comments regarding water quality are contained in the "Water Quality" section of this report.

P

## OIL SPILLS

Section 1.4; Page 1-9.

Question: The document states, "Support facilities and services for tanker unloading facilities would include controls, communications, electric power supply, oil spill containment and recovery and tug services."
- What precisely will these facilities do?
- What exact services will they provide?
- Who pays their cost?
- Oil spill and containment in particular -- what exact services are these?
- Are they proven effective?
- Who pays the bill?
- How many hours away is the service?

Section 1.4; Page 1-10

Omission: No figures are given for the quantity of bunker fuel which will be needed by the ships using the NTPC facility. Nor is the bunkering operation assessed for oil spill dangers. The entire bunkering operation should be examined closely since the danger of spills is probably comparable and bunker fuel is more toxic than crude oil.

Question: The document states, "The fuel oil barges would be equipped with heating coils, pumps, hoses and hose handling gear." What safety measures are there to prevent oil spill and evaporation loss?

Question: Runoff and oily wastes would be diverted to a holding tank installed on each berth platform to process the holding tank contents. How effective would this holding tank be in a storm similar to the one of February 14, 1979, which blew out the Hood Canal Bridge and broke loose many log booms in Port Angeles Harbor?

CONT

Section 1.4; Page 1-11.

Deficiency: The document states, "For a large catastrophic spill the services, equipment, expertise of the Clean Sound Cooperative would be used."
- Much more data is needed to show where it is located and what facilities and capabilities will be available for the NTPC project.
- What techniques do they employ in a large spill?
- How many spills have they effectively cleaned up?
- Would the equipment be stationed in Port Angeles, or how many hours away.
- Could they get here if there were storm conditions?

Deficiency: Equipment to be kept on hand at this location would be determined during the development of the Spill Contingency Plan . . . Where is the Spill Contingency Plan and how do we know the equipment will be adequate?

Question: The DES states, "Semi-permanent oil booms would be installed between ship and shore."
- Have these booms been proven effective?
- Would they work in a storm situation?
- What happens to the contained oil?
- What will happen to that portion of the oil that evaporated and dissolves?
- Will this permanently contaminate our harbor?

Deficiency: The document states, "For a more dispersed spill, NTPC would provide a skimmer recovery vessel." What statistical evidence is available to show that this skimmer recovery vessel would get the oil? What water conditions will limit its operation?

Section 1.4; Page 1-11; Column 2, Paragraph 2.

Deficiency: "Preliminary studies by NTPC indicate that leaks as small as 50 to 100 barrels or 0.07 to 0.14 percent respectively, of the contents of one line could be detected." This statement is ambiguous. It gives no indication of the time over which lesser quantity leaks could be released without detection, how long it would take after detection for a minimum leak to be repaired or how much oil would be released before repairs were completed. It is also inconsistent with the handling of oil leaks from the pipeline, see page 3-70, Table 3.2.6.2. The document indicates that only gross leaks would be noticed by the secondary leak detection system. This should be emphasized in the risk analysis section.

Section 1.4; Page 1-11.

Omission: The leak detection system in use during operation of the underwater pipeline is said to detect leaks of .5 percent of the pipeline capacity. What is not stated is that this is 500 barrels per hour per pipeline. Any leak of that size or less would have to be detected visually either by chance or during the "twice daily" check of the system by small craft.

Omission: The leak detection system outlined in this section depends upon the action of a dispatcher to shut down the system in the event of a leak. There is no discussion of the possibility of human error in this process or of what time lag might be involved.

Omission: It is stated that "relatively small amounts of oil would produce a sheen on the water surface that could be detected visually." What does "relatively small" mean? It is stated that the submarine pipeline would be buried "beneath the harbor bottom at sufficient depth to minimize the possibility of ship's anchor damage." What, exactly, does "sufficient depth" mean, in feet, and what does "minimize" mean (i.e. is it different from eliminate)?

Section 1.4; Page 1-14.
Question: "Recovered oil would be transferred back to storage. The effluent would be piped to the main oil $H_2O$ separator for final processing." What happens to the water that has dissolved hydrocarbons in it when it mixes with oil?

Section 1.4; Page 1-24; Column 2, Paragraph 2.
Deficiency: The DES indicates there are no scrapers in the underwater pipe system. Does this imply problems associated with build-up in mainland pipelines are not inherent in the underwater lines and therefore, scrapers are not needed? If launching and receiving sites are not located at pump stations the statement should discuss diking and spill protection at these stations.

Section 1.4; Page 1-31.
Deficiency: The DES states, "Deviations as small as 0.5 percent of the pipeline throughput would be detected and would provide a leak alarm within two minutes of the incident." How much oil can leak from the system without being detected?

Section 1.4; Page 1-49.
Deficiency: the document should give source data to justify the statement that: "The system as proposed would be redundant and estimated to have a reliability of 99.9 percent." What does this mean in terms of failure rate and in losses of oil which could go undetected or in inappropriate responses to signals to control valves? What is the response time of personnel to emergency situations at each of the unattended facilities?

Section 1.4; Page 1-55.
Deficiency: The "Spill Contingency Plan" outlined is inadequate. It does not call for pre-spill assessments of the biological and geological characteristics of the potential areas of impact. It does not mandate the acquisition of adequate clean-up equipment by NTPC (it calls only for lists of what equipment is on hand to be available--lists, rather than equipment). The plan calls for "initial" instruction for all personnel. What does that mean? The plan calls for action to be administered by NTPC "operating and management staff personnel" -- are they best qualified? Are they impartial, especially in regard to potential cost of clean-up operation?

Additional Concerns with Section 1.4

1 Omission: It is not an uncommon practice in this harbor for ships to drop anchor near the mouth of the harbor to help bring the vessel to a halt. What studies have been made of anchor penetration into the harbor bottom? If this has not been done, what is the basis for determining depth of pipeline placement in the harbor? What burial depth is currently planned for these cross-harbor lines?

CONT

Omission: Onsite storage, Green Point: How many tanks will be used for 1.283 million bpd? Show in figure 1.4-3 how they would be arranged. What water-proofing (oil proofing) material will line the basins surrounding the tanks? Give total volume of storm run-off for the fully developed facility (1.283 million bpd) and describe the amount of oil which will be discharged after the oil-water processing. This should include the oil dissolved in the water. Where is this discharged? What are the long-range, life-of-project to end point of oil-degradation, effects on the environment of such discharges?

Deficiency: Submarine pipelines: At a throughput of 1.283 million bpd how much time will the pipeline from berth to storage tanks be inactive? Give backup data and supporting studies for the statement that leaks as small as 50 to 100 bbl. could be detected. In actual practice how often are leaks of this size spotted? What is the theoretical liklihood of a small leak occuring at night when it probably could not be detected early? In terms of bbl. of oil spilled how much would likely escape if a large rupture occurred at a pumping rate of 100,000 bbl per hour a) in the daytime and b) at night? What is the expected "downtime" and the accuracy of measurement expected for the monitoring equipment (flowmeters, computer)? When this equipment is non-functional is the port to be closed down? How large a spill would be detectable by the simultaneous monitoring by computers on the amount of oil sent by the pumps and that showing on tank gauges? What is the normal range of variation permitted? When this has been calculated, please then give the amount of oil which could escape undetected. Include a reasonable response time on the part of the dispatcher.

Question: How is oil in a ruptured line taken out a) if the rupture is near the east end of the submarine line and b) if the break is at the west end? Is there suction capability at each end?

Omission: What size drainage system (to receive oil drained from pumps and piping) is present at the pumping stations? What is the maximum size leak which has historically occurred at comparable pump stations? Since these are un-manned, give the probable personnel reaction time to respond to a leak at each station, taking into account time to reach a responsible person and get him there, and how this might be modified by bad weather, snow, or ice. What would the worst case situation add up to in oil spilled? When block valves at such stations are closed how much oil could still escape.

Deficiency: Emergency block valves are too widely spaced with regard to unique environmental features and could not adequately protect them in the event of a major pipeline failure. It appears that the block valves were located without any consideration of the unique environmental features, protected shorelines, or major stream crossings

Deficiency: No figures are given for oil spill risks with a throughput of 1.3 million barrels a day. All tables which limit themselves to 709,000 bpd and/or 933,000 bpd should be revised to give figures for larger throughput. The ultimate is not 933,000 but 1,283,000 bpd. See page 6-4. Include the full project with 511 tanker calls per year, Class I standards violated 6 to 7 days per year in Olympic National Park, excessive sulfur oxide levels violating the Prevention of Significant Deterioration standards of the Clean Air Act on 32 days per year, one oil spill every 2.3 years for tankers in transit and every 3.9 years for spills at berths, a barge spill every 0.91 years, 1,022 port calls a year for fuel barges. Note that the historic record of spills into Puget Sound show that 77% of the spills there have been from barges. The maximum size of the tankers and the size mix of tankers at the fully developed state of the project should be presented.

Deficiency: The full environmental costs of this project need to be quantified and analyzed. This should include the costs which are external to the NTPC financial statements but which are, non the less, real costs to society. The expected value of damage caused by spills over the actual life of the project should also be calculated. These cost estimates should be made available before any public agency makes a decision which irretrievably commits public resources.

Section 2.1.1.7; Page 2-14.
Question: Why does the table stop at 50 mph wind velocity? Winds of considerably greater velocity are not uncommon to the Strait of Juan de Fuca.

Section 2.1.17; Page 2-20.
Deficiency: The document should discuss the millions of dollars local industry has expended to guarantee maximum recovery of the Port Angeles Harbor, qualifying the Harbor as a Class A - Excellent. ITT alone has spent over $90 million in capital expenditures. This does not include continuing operation and maintenance costs of pollution abatement equipment.

Section 2.1.15; Page 2-38; Column 2, last paragraph.
Error: This is grossly incorrect. The Strait sustains the greatest "part" of total traffic "in the vicinity". All vessels entering Washington's and Canada's inland waters traverse the Strait. Define "vessel activity". Does this include the Puget Sound fishing fleet. There are over 16,000 vessel movements annually off the Port Angeles Harbor in the Strait of Juan de Fuca.

2 Section 2.1.2.7; Page 2-88.
Error: Biological components, page 2-88: Marine areas that might be affected by the pipeline don't start at Hood Canal. The Straits would be affected by in transit oil vessels and by spills at the tank farm and its associated pipelines directly or via Siebert Creek; contamination of the Port would also affect these waters. A break in a line at the Dungeness River crossing or near it would foul up the estuary in Dungeness Bay. A spill in Port Angeles Harbor would also reach the Dungeness Spit and Bay. (See Coast Guard Study of a simulated small spill at Port Angeles Harbor) See also page 3-20, figure 3.1.7-2 where a tanker casualty off Neah Bay in September would coat South Vancouver Island, and page 3-24 where a tanker casualty off Port Angeles in September sends oil all over Dungeness Spit reaching to Southern Lopez Island (figure 3.1.7-6). If the tanker off Port Angeles had a casualty in March, Dungeness Spit again gets coated front and back and the spill reaches Whidby Island, Lopez Island and Burrows Bay. Chronic oil spills at the terminal in Port Angeles "could taint subtidal clams and decrease shrimp, crab and fish sports harvests.

CONT

Some diving waterfowl mortality. Water quality in harbor would be degraded." (Map addendum, page 68) BLM should perform more evaluation in this area.

3 Section 3.1.4; Page 3-12.
Question: The document states, "A large magnitude seismic event exceeding design criteria could occur; however, based on historical records . . . the probability is low." What are the historical records? What is the probability of a large earthquake?

4 Section 3.1.4; Page 3.12.
Deficiency: The DES states, "Where the pipeline or onshore facilities would cross or be located close to areas of known or suspected slope instability, such as the coastal bluffs, damage from slope failure could be high." What happens when a rupture of this magnitude occurs? What is the probability of its occurance?

5 Section 3.1.6; Page 3-14.

Question: Hydrostatic test water is taken from the watershed and a corrosion inhibitor and a bacteriacide are added. This will involve over 1,000,000 barrels (42,000,000 gallons) of water. This water is then dumped into Sieberts Creek and flows into the Strait of Juan de Fuca. How do we know what the effects of this "polluted" water will be?

Deficiency: The dissolved hydrocarbons from the oil/water separators are to be discharged into Sieberts Creek. This will have serious impacts on the Creek (according to Norhtern Tier's own study). This discharge should not be allowed. It is Northern Tiers responsibility to get this water to the Strait. Is it necessary that the effluent go into Sieberts Creek?

Deficiency: What are specific dangers related to abandonment and removal of oil from storage tanks, submarine pipelines and dismantlement of tanks?

6 Section 3.1.7; Page 3-15.
Deficiency: The Port Angeles harbor submarine pipeline construction short term would degrade water quality with suspended solids, less dissolved oxygen, uptake of heavy metals and chlorinated hydrocarbons by intertidal and subtidal clams; consumption of contaminated shellfish could affect human health. (Item 2, page 68 of Map Addendum) Rupture of Port Angeles pipeline to shore would have critical effects on shellfish, waterfowl would experience mass mortality in Port Angeles, offshore Green Point and Dungeness Spit. Consumption of contaminated marine life would present a health hazard. Why are these materials buried in the Addendum? Why are not impacts on Protection Island included? This is an outstanding habitat for seals and birds such as the rhinocerous auklet, tufted puffin and seagulls. These matters should all be futher discussed in the main document.

7 Section 3.1.7; Page 3-16.
Omission: There is no analysis of the risk of spills of bunker fuel shipped or barged in to fuel the oil tankers.

8 Section 3.1.7; Page 3-16, Column 1.
Deficiency: The doucment states, "The reported numerical risk values are not final statistical representations of frequency and magnitude and may change with analytical refinement." How can one truly understand the risks until these valuations are complete?

Section 3.1.7; Page 3-16.

Deficiency: Although the reliability of statistical methods is hedged in the ES, it is not clearly stated, as it should be, that there are no firm and accepted means for calculating oil spill risks. The majority of tanker and oil transfer spills results from human error. It is impossible to objectively quantify factors such as crew fatigue, language barriers, adequacy of crew selection and training, etc. A risk analysis must make subjective judgments on these and many other factors--the very factors that are most likely to cause spills.

9 Question: What is the degree of reliability of the trajectory studies? How do we know, with 95% confidence, what will happen?

Section 3.1.7; Page 3-16; Column 1, Paragraphs 4 and 5.
Question: Paragraph 4 lists estuarine currents as a factor in movement of oil spills. Why then do the oil spill trajectories not contain an estuarine current component?

Section 3.1.7; Page 3-17.

Error: Table 3.1.7-1 (Frequency of Tanker Spills) and Table 3.1.7-2 (At Berth Tanker Spills) are based on port calls for 933,000 bpd throughput rather than total volume throughput of 1.3 mbpd and three berths and three submarine pipelines. Also tables 3.1.7-3 and Table 3.1.7-4 are based only on two berth operation, not the total project.

10 Question: The DES states, "The estimates (for spill risks) are valid only if conditions do not change significantly from historical patterns." Is this reasonable, or does it undermine the efficacy of the entire spill risk analysis?

11 Error: "Since the exposure variable for fixed berths (i.e. the chance of a spill at a fixed berth) is the number of port calls per year these (spill) frequencies would be applicable to all ports using fixed berths." This implies that all fixed berth oilports have the same risk factors for ships at berth. This seems highly unlikely. BLM should clarify this statement.

Omission: No source is given for tables 3.1.7-1, 3.1.7-2, 3.1.7-3, or 3.1.7-4.

12 Deficiency: In analyzing pipeline spill risk, the DES uses pipeline mileageas the "exposure variable". The report admits that is would have been preferable to use volume throughput as the variable but claims the volume figures were unavailable. The final DES must have the pipeline risk analysis based on volume.

126 CONT

⑬ Section 3.1.7; Page 3-18.
Deficiency: The document reports that, "An oil spill within Port Angeles Harbor would likely spread quickly enough to impact the shoreline before it could be transported out of the harbor." An oil spill contingency plan is not included in the DES. It should have been included and thereby allow government and public reviewers to critique the contents. Significant questions, including those regarding clean-up equipment, personnel, liability, resource recovery, etc. have yet to be addressed. Such an omission would constitute another justification for the issuance of a Supplemental Environmental Statement.

Section 3.1.7.
Comment: There is a need for a fundamental review of the risk analysis performed by the Oceanographic Institute of Washington (OIW). Concern is primarily with OIW's methodology. A review of past activities of the OIW regarding transshipment in Washington State should have been made prior to contracting for the subject risk analysis. OIW's involvement in this area is not without controversy.

In 1972, the Oceanographic Commission of Washington (OCW) published a Risk Analysis of the Oil Transportation System which was, in essence, a prelude to the growing debate over tankers in Puget Sound. In 1974, after lengthy legislative debate, the OCW published an offshore petroleum transfer systems feasibility study which was designed to demonstrate the viability of a major oil port "at or west of Port Angeles." OCW's report received legislative criticism for its bias.

Subsequently, in 1975, the OCW promulgated a four-point State Oil Transportation Policy which not only advocated a new single, common-use crude oil terminal at a site in the Port Angeles "vicinity", but also proposed that the State encourage construction of such a terminal through an economic incentive. In 1977, the OCW went one step further and urged the 45th Legislature of the State of Washington to enact legislation which would site a new crude oil terminal at or west of Port Angeles. At that point, the OCW got into the business of proposing and promoting legislation on this issue. It is a serious concern that BLM would let a contract for risk analysis to an institution with that kind of bias. It is acknowledged that the Oceanographic Institute of Washington, as distinct from the Oceanographic Commission of Washington, is a research institution. But it should also be recognized that the OIW is the corporate arm of the OCW. The enabling statute of the State of Washington clearly states that: "The OIW shall . . . coordinate, promote and carry out such policies . . . as may be formulated by the Commission." (RCW 43.94.050) Therefore, the entire work product by OIW for this EIS is subject to question.

In light of the OCW's espoused position on this issue then, it is not at all surprising that the OIW's risk analysis performed for BLM continues to allege the comparative assets of an oilport at or west of Port Angeles. In fact, to quote OIW's current work product, this latest effort nearly "constituted a refinement by the OIW of past risk analysis methodologies, many of which used port calls as the exposure variable." (Fires and Explosions: II-1)

It is interesting to note that back in 1972, before the OCW had a position on this issue, the OIW did not embrace this methodology so enthusiastically. In fact, OCW gave credence to the contention that "you can't compare ports because the topography is different and the number of ships utilizing any two ports may be significantly different." (Page 357) For example, just as you can't compare Port Valdez and Rotterdam, you can't compare the Strait of Juan de Fuca and North Puget Sound. Of the approximately 5,000 vessels entering the Vessel Traffic System (VTS) at Cape Flattery and traversing the Strait of Juan de Fuca, only 7% proceed to North Puget Sound. Less than that ever reach Cherry Point. That constitutes a staggering difference in vessel traffic densities between the navigational approaches to Port Angeles and Cherry Point. It is evident to most lay people that the Strait of Juan de Fuca sustains the maximum traffic density of Washington's inner waters. Port calls are clearly secondary to site exposure based upon traffic densities.

To assist in understanding this, one might examine what a comparison of Cherry Point and Port Angeles on the basis of port calls really means. It is true that x number of tankers call at Anacortes each month, y number of tankers call at Cherry Point each month, z number of tankers call at Tacoma each month, and so forth. Apart from occasional layovers at Port Angeles, none of these tankers literally call at Port Angeles. ⑭ Yet all of these tankers traverse the Strait of Juan de Fuca, regularly exposing Clallam County and Vancouver Island to the risk of a major oil spill. The net impact of x,y and z tanker traffic is concentrated in the Strait of Juan de Fuca--not at Cherry Point. This, of course, is not only not reflected in the OIW risk analysis but clearly circumvented.

OIW and BLM go on to postulate that the longer the distance traveled for a port call, the longer the tanker is exposed to hazards and events that cause casualties. (II-2) Is this ES assessing risk probabilities associated with a migrant tanker fleet enroute to inner Puget Sound or is this ES attempting to assess the frequency with which alternate port sites are actually exposed to tanker-related casualties?

In order to consider this in a larger perspective, one might take note of the methodology section of another Federal ES, published by the FEA in 1976 (Mandatory Canadian Crude Oil Allocation Regulations/DES 76-1: A-4) which acknowledges that the incidence of both tanker casualties and spills is proportional to the length of time and number of times tankers spend in various waterways. Port calls and distance were not factors.

One additional comment about OIW's approach to comparative site assessments. To quote the draft ES: "It was assumed that the current ban on tankers greater than 125,000 dwt east of Port Angeles did not apply. This allowed comparison of all of the alternate port sites with the proposed Port Angeles site."

First, there are currently no proposals for the transshipment facility at either Burrows Bay or Cherry Point. Secondly, current Federal law precludes any serious consideration of such a facility east of Port Angeles. Thirdly, a current Federal administrative order precludes supertankers from inner Puget Sound.

Then why are BLM and OIW using inner Puget Sound port locations as hypothetical port alternatives? Why are BLM and OIW dwelling on potential incremental risk based on distance traveled to Cherry Point when all factors are far from equal? There appears to be little merit in this kind of approach except for serving the express policies of the Oceanographic Commission of Washington. If BLM felt the need to make comparisons with inner Puget Sound site locations, then why weren't the comparisons realistic?

CONT

In OCW's 1972 report: "The final test of any mathematical model is how well it fits physical reality . . . But the key to testing the 'goodness of fit' of a mathematical model is the use of an adequate and unbiased data base. . . Once we start compromising the data base, the results can go from fair representation to being totally misleading." (Page 365) That Aptly summarizes differences with OIW's 1979 risk analysis for this ES. It would seem that OIW and BLM have seriously compromised the risk analysis methodology and the result is "totally misleading".

⑮ Section 3.1.7; Page 3-25; Column 1; Paragraph 4.
Error: The oil spill risk for a submarine pipeline rupture based on 50,000 barrels per hour is incorrect. Project design is for a 100,000 bph pump rate for each line for 300,000 dwt tankers. (Project Description of the Site Certification Application, Volume 1, page 6-9) BLM should correct this."

Section 3.1.7; Page 3-25; Column 1; Paragraph 5.
Deficiency: What is the maximum submerged pipeline spill potential? With a maximum of 100,000 barrels per hour times .05% leak rate, the spill for one line would be 500 barrels per hour.

Section 3.1.7; Page 3-25; Column 1; Paragraph 5.
Deficiency: the document does not address the procedures to be used to repair the submarine pipeline after a rupture or leak. Nor does it discuss the damage impact potential of such a repair operation. Further discussion of the matter is warranted.

Section 3.1.7; Page 3-25; Column 2, Paragraph 3.
Comment: Tar balls also float to the surface. The floating balls attract birds which become coated and usually die. Oil that becomes impregnated with salts is nearly impossible to clean from birds.

⑯ Section 3.1.7; Page 3-25; Column 2, Paragraph 5.
Deficiency: This is a paragraph of technical data describing the immediate effect of an oil spill. What does this data mean? This paragraph alone is not an impact. It should identify the impacts in terms of fish kills, bird oiling, etc. that can be expected to result from the project.

⑰ Section 3.1.7; Page 3-32.

Deficiency: "Depending on the spill size, crabs and shrimp could either be killed or suffer sublethal toxic effects . . ." This is not sufficient analysis. Where are the numbers: what size spills would produce how many dead crabs, etc?

Question: The statement is made: "Ingested oil from contaminated prey would not affect pennepeds significantly." What is the source for this statement? What documentation is there? Note the conflict with later statement on the same page: "Oiled birds would ingest significant quantities of oil while preening their plumage and the ingested oil would inhibit reproduction." Are pennepeds (seals and sea lions) so much different from birds?

Section 3.1.7; Page 3-32; Column 2; Paragraph 2.
Comment: Oil spills, especially small quantities over long periods could displace food fish which would disperse birds from areas that are traditional protected shelter areas. If birds are forced into open, exposed waters during storms they can become stressed and their chances for survival are reduced.

⑱ Section 3.1.12; Page 3-41; Column 1, Paragraph 1.

Error: An oil spill of much less than 420,000 gallons (10,000 barrels) inside the harbor could significantly impact sandy beach or land areas of Ediz Hook requiring intensive cleanup and possible removal of oil soaked soil.

Comment: Paragraph three describes a spill of 10,000+ as catastrophic. Paragraph two assumes a spill of 100 barrels would impact adjoining land.

⑲ Section 3.1.12; Page 3-41; Column 1; Paragraph 3.
Omission: There is a strong concern with impacts of oil mixing with wood chips and other log boom related waste products. Will it allow oil to accumulate into oil balls more rapidly and sink or will it create floating mats of oil? The combination in this area could have significant impacts on resources. An investigation and discussion of these probabilities should be presented in depth.

⑳ Section 3.1.14; Page 3-48; Column 1, Paragraph 4.
Omission: BLM should present a worst case impact figured in 1978-79 dollars. The statement does not discuss what the impacts a 50-100 barrel, undetected leak would have if it lasted one day or one week. It also does not state how much oil would be spilled before such a leak was detected and repaired. Many general statements are meaningless.

㉑ Section 3.1.15; Page 3-51; Column 1; Paragraph 3.
Omission: The document gives Canadian estimates of the clean-up costs per lineal foot of shoreline. Based on these figures BLM should calculate the estimated cost of each of the project spills identified on the trajectory maps in the risk analysis section. Also, the estimated clean-up costs of a 50-100 barrel undetected accident and 10,000 barrel major accident in Port Angeles Harbor should be stated.

The clean-up activities should be in detail. Discuss material removal, sterilization, oil removal, etc. Identify mitigation to replace clam beaches and other resource areas if they will receive secondary impacts of clean up.

㉒ Section 3.1.15; Page 3-51; Column 1, Paragraph 6.

Deficiency: Torrey Canyon spill in 1967 (12 years ago) cost 27½ million for clean-up costs alone. What were the economic impact costs from that oil spill and who and how much was paid out in damages relating to same? What method of collection was used to get payment? The Amoco Cadiz liability problems represent a current example of problems in this area and should be thoroughly discussed by BLM as a case study.

Question: How much money is now in the $100,000,000 Trans-Alaska Pipeline Liability Fund? How much has been paid out since it was created in 1973? What protection is there and what kind of liability fund exists for damages from Alaskan oil spills at berth or from fires or explosions related to same?

CONT ㉒

Deficiency: More specific information is needed as to how private industries and citizens file claims and receive payment to cover damages incurred from major or minor spills.

Deficiency: The DES discusses TOVALOP and CRISTAL, two international oilspill liability programs. Figures given show liability limits of $10 million and $30 million respectively. Liability claims stemming from the Amoco Cadiz spill total hundreds of millions of dollars (over three billion dollars according to one press report). A candid discussion of maximum liability problems should be presented by the BLM.

Section 3.1.15; Page 3-55.

Deficiency: the document does not adequately address the specific impacts of a major oil spill. What effect would the delays in collecting damages and the costs relating to lawsuits have on the ability of industry and individuals to recover from the spill?

Error: The DES states that "data indicating the probability of a major fire or tanker explosion are currently unavailable." These data are given, however, in Table 5.1.12-2, page 5-9. There is no documentation of the effects of a fire or explosion.

㉓ Section 3.2.6; Page 3-67.
Question: Concerning risks of spills from pipelines, it is said that with new pipelines, "there is a leak rate of 0.0022 leaks per mile per year." This study then computes the total miles of stream crossings and determines (for a 20 year project) that 0.31 spills would occur. Is it documented that pipelines under streams have essentially the same risk of leaks as those underground? To several reviewers this statement seems improbable. BLM should clarify and document this statement.

㉔ Section 3.2.6; Page 3-70.
Deficiency: The DES states, "In the remote chance of a spill, the severity of impact on stream water . . ." The "remote" chance is 31% according to the DES figures on page 3-67. BLM should clarify the statement.

Section 5.1.7; Page 5-6.
Comment: Under "Operation Phase" the DES states "Chronic oil spills from tanker off loading could cause 'subtle' changes in organisms and communities . . ." Page 3-28 says, "Spill impacts from acute, short-term exposure to large quantities of oil or chronic long-term exposure to small quantities of oil would result from the chemical (toxicity) or physical (smothering) characteristics of the oil." "Biological impacts would include: 1) adverse effects on human health from eating contaminated seafood, 2) decreased fishery resources, 3) modification of marine ecosystems by the elimination of species which decreases ecosystem diversity and/or productivity, and 4) modification of habitats and delay or prevention of recolonization."

㉕ The use of the word "subtle" to describe these changes is unfortunate. The word can mean: thin, rare, tenuous, not dense or heavy. An it can also mean: keen, acute, hard to detect, intricate, and acting in an insidious way. It would be more proper, therefore, to avoid any chance of misunderstanding by rewriting the lead sentence to accurately reflect the adverse effects as listed on page 3-28. A possible revision would read, "Chronic oil spills from tanker off loading would cause drastic changes in organisms and communities . . ."

㉖ Section 5.1.13; Page 5-9; Table 5.1.12-2.

Deficiency: The risk of a large oil spill in the harbor is stated to be one per 255 years. This is not consistent with Northern Tier's analysis in their site application. (Compare page 8-38 of that document)

Deficiency: In discussing the impact of a tanker explosion in the harbor, the DES states that such an explosion "might cause physical damage, loss of life at the Coast Guard Station, nearby vessels in the harbor, and recreationists of Ediz Hook." No references are given for these conclusions. According to John Wiechert of the Clean Sound Cooperative, the risks are substantially greater than this, including significant danger to Port Angeles, the Olympic Memorial Hospital, and the Coast Guard Stateion. An in depth analysis of this potential hazard is mandatory.

㉗ Section 6.1; Page 6-2.
Error: The BLM-DES makes the statement, "A major spill is not likely to occur diruing the lifetime of the project." This statement is just not true. The Northern Tier application states, on page 8-38, that with 3 berths there is a 40% chance of a total vessel loss during the projects life.

㉘ Section 6.3; Page 6-4.

Deficiency: Table 6.3.2-2 shows the estimated frequency of in-transit tanker spills.
- Did the OIW take Canadian shipping into account?
- Did the OIW take Port Angeles-Victoria traffic into account?
- Did OIW take into account the fact that with increased tanker traffic, tanker spills increase exponentially, not arithmetically?

There is no answer to these questions. Such areas of concern should be discussed, and the answers documented.

㉙ Section 6.3; Page 6-6.

Question: Table 6.3.2-4 is entitled: "Estimated Frequency of Explosion and Fire Casualties Involving NTPC Tankers Traveling to P.A." What is a casualty?

㉚ Section 8.2; Page 8-3.
Question: The document states: "Operation (of a submarine pipeline) would increase the risk of marine oil spills." Compared to what? How great an increase?

㉛ Section 8.4.1.1; Page 8-12; Paragraph 4.
Comment: If a spill were to have an impact on the nearly level and fertile land in the Cherry Point area, it is more than probable that a spill in any one of the irrigation ditches or in the Dungeness River would have an impact on fertile farm land in Clallam County.

㉜ Section 8.4.1.6; Page 8-45.
Deficiency: Table 8.4.1.6-5 indicates that an onshore pipeline of only 117 miles, from Cherry Point to North Bend, would spill 1100 barrels per year, and yet a longer line (200 miles) from Low Point to North Bend would spill only 876 barrels per year. There should be adequate data shown to support these conclusions.

CONT ㉜

Q

## SCHOOLS

The following information was submitted to the Task Force by school district administrators. Although the comments primarily address the Northern Tier Pipeline Company Application for siting certification to the Washington State Energy Facility Site Evaluation Council, the concerns expressed are generally appropriate in regard to information contained in the Bureau of Land Management Draft Environmental Statement.

Additional information regarding school system impacts resulting from the NTPC proposal are contained in the analysis of project impacts provided by Mr. Reed Hansen, Urban Institute, Washington, D. C. The analysis is attached as Appendix "A" of this report. Mr. Hansen produced his analysis while under contract to the Oilport Task Force.

### REACTIONS TO EXCERPTS FROM
### THE NORTHERN TIER PIPELINE
### APPLICATION FOR SITE CERTIFICATION

① Page 1.15-10, Table 3-1.15-2 - Data reported is felt to be incorrect. Actual Sequim School District enrollment data is currently more than one hundred students in excess of the enrollment projected for 1980.

Page 1.15-10 - The impact statement does not reflect the current school construction program in the Port Angeles Public Schools.

Page 1.15-11 - (the second complete paragraph) Private Schools - the impact statement is inaccurate in the number of private schools in the area. There are two private schools serving the Sequim District. The Port Angeles School District also has two private schools. I believe there is evidence that indicates that Port Townsend also has a private school.

② Page 2.15-1 - Introduction Statement - The Northern Tier indicates that, "the possible effects of population growth on schools will be negligible and are not addressed." Certainly the impact when compared with other realms of the entire impact statement may appear, and indeed be, small. The impact will, however, have significant financial effects on the Districts' financial status. Although the State, through the Basic Ed funding commitment, will provide for the operating costs of any additional impact students, capital costs for additional transportation, classroom teaching space, equipment, and instructional materials may be completely covered by the State.

Pages 2.15-7 and 8 - The Committee felt there was a need to verify the assumptions used by Northern Tier with respect to construction workers and school age children.

③ Page 2.15-10 - "In no case would NTPS induced employment during the operational phase generate a school capacity problem that would not exist otherwise." It must be clear that regardless of existing enrollments, any influx of students caused by temporary employment for pipeline construction as well as other activity of the Northern Tier Company would indeed have an impact on schools. It is simply not accurate to say that because schools in this area are considered by Northern Tier to be presently over capacity in enrollment that the influx of Northern Tier employees would have no impact. Impacts would exist in the need for additional transportation, classroom student equipment, books and other instructional materials, as well as the need for additional classroom space in some school districts.

Page 2.15-20 - The first paragraph of conclusions quoting the statement "Northern Tier will cause increased enrollment in the four school districts that serve the area for the marine terminal. In no instance will these increases be the cause of school capacity deficit. .....the project related enrollments will aggravate classroom space inadequacies." We would like to add in that it must also be noted that in addition to transportation, classroom space, equipment, instructional materials including textbooks will be impacted by the influx for an oil terminal.

④ With respect to Section 5 - Public Services Committed Mitigation Measures - It should be noted that under the section, Other Services, the mitigation proposed by Northern Tier Pipeline System (NTPS) is limited to advice and assistance for school districts in their efforts to identify government or other programs, grants or loans that might assist in mitigating the impact of the oil terminal. The people of these communities are not going to be in need of advice and assistance as much as direct financial assistance for those impacts which are not covered by the usual State or Federal sources for assistance in meeting local services.

Page 6-18, Section 6.15.1 - The NTPS makes comment relative only to school capacities. It does not in any way consider school needs in the areas of transportation, capital equipment, books and other instructional materials. The environmental impact statement tends to minimize the effect of the proposed project. The salient comment in this section which is repeated throughout the document, might be "project related enrollments will aggravate classroom inadequacies in the four school districts."

Pages 7.2-128-129 - It was important to the Committee that it be noted that during project construction about one hundred-fifty additional pupils would be enrolled in the four school districts and that about sixty additional students would attend as a result of the operation of the NTPS. These additional students will reflect an impact in capital costs as well as transportation, textbook, and other instructional material areas. The Committee's position is this: The influx of the additional students that were projected in the environmental impact statement will create an impact for which mitigating measures must be taken. The Committee is not interested in bleeding Northern Tier for mitigation of existing problems. It must be pointed out, however, where an additional number of youngsters enroll; transportation, furniture, textbooks, other instructional materials as well as space must be provided, regardless of how crowded or regardless of present enrollment. If an additional 150 students appear, 150 sets of equipment will be necessary. School Districts do not store additional equipment in reserve in the event that a pipeline might be built in their community. And conversely, if equipment is purchased and the enrollment declines as a result of a construction phase being completed, what does a school district do then with the additional equipment that has been purchased for these youngsters? The point is clear, an impact would exist and although it might be minimal, as Northern Tier has indicated in the overall impact statement, it could be of major proportions to some of the school districts involved.

126 CONT

REACTIONS TO EXCERPTS FROM
EFFEC CONSULTANT REVIEW OF
NTPC APPLICATION

Page 242 - The application materials indicate, "current staff/student ratios for both districts are at or below state-wide averages. As shown in Table 2.1.15-9 Port Angeles School District could accommodate some additional students in the lower grades."

COMMENT: The current student/staff ratios in the Port Angeles School District are what they are by design. It has been a matter of policy as well as intense effort to bring the class loads in the lower grades to the level that is now in existence. Certainly, none of the applicants nor consultants would suggest that they are attempting to dictate district operation by determining teacher/pupil ratio levels at a level higher than the District is attempting to achieve. If additional students are generated at those grade levels in the Port Angeles schools by a contrived influx they would hope to maintain the levels as they are now for current student population as well as for any students who enter the system.

Page 511 - Table 5.1.15-1 - It is noted by the Committee that reference was made to, "unavoidable adverse impacts on schools dependent on timely application for and receipt of assistance."

R

SOCIO-ECONOMIC

Description of the Proposal

① Section 1.4; Page 1-40, 42.
Deficiency: Job descriptions of required construction personnel are insufficient to allow one to determine how many positions could be filled by local workers. Job titles such as "Teamsters", "Semiskilled", and "Operator" do not tell what job skills are required.

Section 1.4; Page 1-50.
Deficiency: Nothing is said about any arrangement to guarantee funds to pay for abandonment and disposal when the time comes. A statement of financial position of NTPC consortium members is not enough. A trust fund (or the legal and financial equivalent) should be established to guarantee sufficient dedicated funds to pay for proper disposal.

Question: Who would be responsible for abandonment impacts and problems if Northern Tier went bankrupt.

Comment. It should also be noted that the project's stated 20 year economic life bears little if any relationship to the actual service life of the oilport and pipeline. The actual date of abandonment is not influenced by the selection of 20 years as the project's economic life.

Description of the Environment

② Section 2.1.1.13; Page 2-32.
Deficiency: Since the BLM DES was published the Hood Canal Bridge has been destroyed. This significant change in the peninsula's transportation network should be analyzed in terms of its effect on at least the following:
a. Transportation of construction materials to Clallam County.
b. Transportation of commuting workers.
c. The availability and price of consumer goods in Clalam County.
d. The effect on tourism in the county.
e. The ability of the local hospital to transport patients to Seattle.

③ Section 2.1.15; Page 2-38 through 47.
Omission: In describing the current social and economic conditions existing in Clallam County, this document expresses (page 2-46) a need for a more diversified industrial base and for additional jobs to stop youth - out migration. Yet the document omits any mention of the Clallam County Overall Economic Development Plan - a current plan, updated annually by a committee of more than 25 local business leaders working through the Chamber of Commerce. The goal of the plan is to "identify and set priorities to projects and programs that will reduce the County's unemployment rate." The 1978 plan lists 18 short-range, 8 mid-range, and 8 long-range projects, all of which could help the County reach its economic goals without the risks associated with an oil port. Therefore, the BLM statement of current social and economic conditions is incomplete.

④ Section 2.1.1.15; Page 2-39.
Question: How is the distribution of commercial catches defined? There are no refrigeration facilities in Port Angeles so a majority of the catch in the Strait is logged at other inland harbors.

⑤ Section 2.1.1.15; Page 2-41.
Question: Does table 2.1.1.15-6 include retirement income and Social Security benefits? Later data on wage and salary employment are available and should be used.

⑥ Section 2.1.1.15; Page 2-46; Column 2, Paragraph 3, last sentence.
Error: The BLM document states: "The Company is making plans to fund studies of impacts (NTPC 1978." The NTPC is not funding local impact studies. This need to be corrected.

⑦ Section 2.2.1.2; Page 2-154.
Question: The BLM document states "According to the Olympic Air Pollution Control Authority no new major industry is expected in the near future." Why should the pollution control authority be quoted as the expert on industry's location plans? What is the basis for this claim? BLM states without documentation that overall air quality in Port Angeles is expected to remain at about present levels. Since this section of the document deals with conditions through the year 2000, such broad statements should definitely be documented by supporting evidence.

⑧ Section 2.2.1.15; Page 2-156.
Omission: In discussing the future environmental conditions that could be expected if the Northern Tier project were not built, the document leaves out any mention of the short, medium, and long-range projects proposed in the Clallam County Overall Economic Development Paln, 1978.

⑨ Section 2.2.1.15; Page 2-156.
Deficiency: Not a word is written about the future plans

CONT

⑨ of any industry presently located in Clallam County. The documents general statement "The principal industries of the local economy are expected to continue to grow," is hardly a sufficient description of the economic climate expected through the year 2000.

Impacts of the Proposed Action

Section 3.1.8; Page 3-34, Column 2.
Omission: An amortized economic loss to resources, considering a 100-year impact or even a perpetuity impact, should be compared against the positive benefits over a 20-year life.

⑩ Section 3.1.11; Page 3-37.
Deficiency: Visual impact of 25 storage tanks each 56 feet high and 285 feet in diameter, will be significant. What effect will this impact have on property value for current residents and future area development by landowners? How will they be compensated for this impact?

Deficiency: What measure will Northern Tier take to mitigate impacts to tourists and residents from visual intrusion for the life of the project?

Deficiency: The document does not speak to the total project with three berths. The addition a a third berth would further impact all visual resources.

⑪ Section 3.1.12; Page 3-39.
Deficiency: The BLM document states that relocating log storage will cause economic, traffic and air quality impacts. However, no discussion of these impacts is provided. Since these log displacements will definitely occur if the project is built, then these impacts should definitely be explicitly addressed.

⑫ Section 3.1.13; Page 3-46; Column 1; Paragraph 1.
Deficiency: The document states, "The Coast Guard's air operation at Ediz Hook might be adversely affected . . ." The constraints placed by this project on the Coast Guard's air operations should be discussed thoroughly.

⑬ Section 3.1.15; Page 3-49.
Omission: There is no Fiscal Condition sub-paragraph in this section. There are many generalities about increased costs of providing additional public services. The mitigation section even provides a partial list of available funds which, this document states, would probably apply to the construction phase. Yet no specific data are given concerning the dollar amounts of the impacts that need mitigating. A rigorous cost-revenue study of the project's impacts is needed before making requests for financial assistance.

⑭ Section 3.1.15; Page 3-49; Column 2, Paragraph 1.
Question: Are all social-economic impacts based on the 18 month or 22 month minimum periods for construction? Eighteen month and 22 month periods are interchanged. What would be the maximum construction period taking possible delay factors into consideration?

⑮ Question: What impact would Taxation Valuation Increases have on all segments of the community? What is the probable impact of pending alternative tax proposals on the projected revenue to be provided local governments in our area if the project is constructed and operated? Various proposals have been discussed by the House Revenue Committee and could be readily analyzed by the applicant.

⑯ Error: Any increase in costs to the operation of local mills would (not could) reduce their profits.

⑰ Section 3.1.15; Page 3-49, 50.
Deficiency: The document states that the population of Clallam County would be temporarily increased beginning four to six weeks in advance of the initial construction period, and that this would consist of less than 50 advance construction personnel. The document also states that "it is unlikely that many job seekers would stay without employment."

These statements should be justified in light of the experience of other major energy development projects and the set of unique living conditions and amenities found in the Clallam County area. The job may attract more workers than needed (as happened with the Alaska pipeline construction) and the document has not addressed the impacts if the unemployed stay in the county.

Indeed, the labor economics theory suggests that a more probable situation is as follows:

a. Would-be workers migrate into an area before construction in order to establish residency whenever the announced hiring policy is to hire local workers first.

b. Unemployment steadily increases before the project as workers pass up jobs in order to be available for the higher paying project.

c. As currently employed local workers leave their jobs to take the higher paying project jobs, the disappointed in-migrants take the jobs left open by the local worker switch.

d. Unemployment rises and stays high upon project completion when local workers find their old jobs filled, but are very hesitant to leave their home town to look for other work.

⑱ Section 3.1.15; Page 3-50.
Error: The statement claims that 110 more (secondary) jobs would be generated by construction workers expenditures (that is "induced" employment) and local construction procurement (that is, "indirect" employment). Page 1-40 and 1-41 pretty well establish that very little construction materials will be manufactured or purchased locally. Thus, this "indirect" employment multiplier effect is probably overstated.

⑲ Deficiency: Also, the statement should document the estimate of 160 local workers out of 750 peak jobs. How was this number developed? In its examination of the NTPC's site application, CH2M Hill stated that "to the extent that local hiring involves currently employed workers rather than unemployed persons or new entrants into the labor force, the project jobs and income are not necessarily a net benefit to the community."

⑳ Error: Employment and population effects of the Operation Phase could be underestimated due to the following:

CONT

⑳ 1. Relocation of ship crews and families to Clallam County.

2. Build up of ship services and maintenance facilities.

The document states, ". . . tanker crews (and families) would probably not reside in Clallam County even if their ships were based there, since their travel to and from home is at the shipowners expense." This wrongly implies that payment for travel expenses is the criteria for crews locating in one area or another.

㉑ Section 3.1.15; Page 50.
Deficiency: The Environmental Statement submits that damages from an oil spill would have minor effects on tourism perfectly contradicts a statement on page 3-47, paragraph 3.1.14, Recreation Resources, Operation Phase, to the effect that an oil spill or submarine pipeline reupture would substantially disrupt tourist visitations.

The report speculates that oil tanker collision, spills, etc. would "affect a significant number of recreationists."

How then, can the report make the assertion three pages later that damages from an oil spill would have minor impact on tourism? The example of a 10% decrease in tourism at Santa Barbara, California being offset by increased motel business in the rest of that county is an invalid comparison. Port Angeles is the major urban center in Clallam County, and its harbor is the center of its recreational activity. Port Angeles is the gateway to the Olympic National Park and the U. S. terminal for the Victoria, British Columbia ferry traffic. The rest of Clallam County does not have sufficient tourist accomodations to offset the financial loss to the county of a major oil spill at Port Angeles.

The document does not quantify the losses of tourist business that would result from an oil spill. The environmental statement should either make a rigorous analysis of the tourist business in Clallam County and show why tourist business losses would be small, or the statement should explain why Santa Barbara and its tourists are so similar to Clallam County and its tourists that virtually the same result could be expected here. Additionally, data should be presented to allow one to put the "10% tourist drop" figure in perspective. How do we know that without the oil spill the tourist business might not have been up, say 20% thus making the total loss 30%?

㉒ Section 3.1.15; Page 50; Column 1; Paragraph 5.
Question: What is the basis for assumption that economic loss from tourist trade would be offset by construction worker expenditures? Tourist trade loss could continue past construction phase.

㉓ Section 3.1.15; Page 3-50; Column 2; Paragraph 5.
Deficiency: The BLM ES states "Fish production reduced by an oil spill could reduce the income of commercial and Indian fishermen. Additional work will be done to assess these loses when estimates of biological effects are completed." This document will remain incomplete until this additional work is completed. The ES must assess the probable economic loss to both commercial and Indian fishermen, due to direct fish kills and distruction of spawning sites, over the project's service life (operating life). Secondary economic impacts on local sporting goods stores, marinas and related businesses, such as boat dealers and repair services, should be addressed. The report should also document these numbers and give sufficent details as to how they were calculated.

㉔ Section 3.1.15; Page 3-51; Column 1; Paragraph 5.
Omission: This section is not clear. Will fishermen who lose revenue because they couldn't fish during an accident be allowed to claim those losses? If not how will they be reimbursed?

㉕ Section 3.1.15; Page 3-51.
Deficiency: The document does not adequately address the economic impacts of increased unemployment resulting from reduced profitability of mills' operation and constraints placed on industry by the NTPC project. Specifically, the combined economic impacts of electrical power curtailment and shutdowns due to air quality problems are not addressed. What would be the social impact on the community of such shutdowns and the resulting employment?

㉖ Section 3.1.15; Page 3-51; Column 2; Paragraph 5.
Deficiency: The document states, "Additional personal income generated in the initial construction phase would amount to about $28 million over the construction period. The ES does not tell whether this $28 million is in Clallam County alone or if it is statewide. Also, no information is offered as to how this number was calculated.

Housing, Rents, Impact on Fixed Income People

㉗ Section 3.1.15; Page 3-51; Column 2; Paragraph 5.
Deficiency: The document states, "Rental prices might increase 20 to 25% during the constrcution phase." The ES should tell how percentages were derived. The document does not say whether this rise in rents includes, or is in addition to, normal rent rises that would occur over the 22 month period without the project.

㉘ What is the size of the group of low and fixed income persons who would be "especially affected, because housing costs normally constitute a larger part of their budget"? Population trends and distribution by age shown on pages 2-40 and 41 do not show the large and increasing number of retired persons living in the county on a fixed income. The majority of the people in Clallam County are retired. Social Security benefits amount to $24 million per year (more than the combined payrolls of the four major mills in the county). The applicant has not addressed the impacts on the portion of the people who are retired (and their social and economic contributions to the area) if the amenities and aesthetics of the area are changed. No information is provided on the secondary economic effects that higher housing prices would have on the remainder of consumer spending.

㉙ Section 3.1.15; Page 3-52.
Question: The document suggests that special camping areas be made available by the National Forest Service for accommodating workers. Who would pay the cost of providing this camping space for the workers of a private company? Can any private business ask for and receive this service?

㉚ Section 3.1.15; Page 3-49.
Omission: There is no Fiscal Condition sub-paragraph in this section. There are many generalities about increased costs of providing additional public services. The mitigation section even provides a partial list of available funds which, this

CONT

㉚ document states, would probably apply to the construction phase. Yet no specific data are given concerning the dollar amounts of the impacts that need mitigating. A rigorous cost-revenue study of the project's impacts is needed before making requests for financial assistance.

Unavoidable Adverse Impacts

Numerous adverse impacts which are not discussed adequately or at all by the BLM-DES are mentioned above in the comments on sections 3 and 4. Section 5 of this document should be rewritten to correct its deficiencies.

㉛ Section 5.1.12; Page 5-8.
Omission: Land use. This ES should discuss the foreclosure of other optional uses of the land at Green Point. Port Angeles is growing towards Green Point (to the east of town). There might well be many uses of that coastal bluff land in the next 20 (plus) years that are much better than a tank farm.

㉜ Table 5.1.14-1; Page 5-10.
Omission: The document fails to place a monetary value on the losses caused by various sizes of oil spills. There should be a discussion of the impacts from each oil spill risk analysis scenario in terms of days of use and dollars of revenue lost.

Short-Term uses vs Long-Term Productivity

Page 6-1.
Deficiency and error: This paragraph speaks of Port Angeles as if it were an area of environmental significance, but uninhabited by human life. "Existing environmental values" are not the only short and long term tradeoffs for the area. The future expansion (growth) of the community and its present livelyhood provided by existing industries is very probably threatened because of tremendous social and economic impacts that the Northern Tier project would have on the area.

㉝ Comment: In the Summary at the very beginning of the DES in the second paragraph, next to the last sentence it says: "The project would provide significant beneficial impacts to the economy."

In Chapter 6, page 6-2, first paragraph, next to the last sentence it says: "The project is also perceived as having a short-term and potentially long-term risks to health, safety, and the general quality of life which would not be off-set by short-term economic benefits."

Which statement is correct? How was this determined?

㉞ NOTE: A critical evaluation of this DES has been made by Reed Hansen, of The Urban Institute, Washington DC. His evaluation, which concentrates on the social and economic impacts of the project, is to be found in Appendix A.

We would like answers to each of the concerns and questions raised in that evaluation and expect those topics to be addressed in the Final Environmental Statement.

S

TOURISM/RECREATION

① Tourism is a major industry in Port Angeles and Clallam County and great consideration must be given to insure that the NTPC proposal will not have a detrimental effect on the tourist industry.

This industry depends on clean water, amenities, and recreational opportunities. It contributed $63 million to the county in 1976; between 1977 and 1978, this contribution increased between 15 and 25 percent. The BLM has not adequately addressed the impacts of the project on tourism.

Omission: The economic risks to tourist facility owners and employees should be analyzed by the BLM. "In economic terms, hardest hit have been the hotel owners in this tourist-oriented part of France. They so far have received no compensation from the government for losses suffered from reduced summer tourism, put as high as 75%....estimates by the regional tourist association that 12,485,000 tourists canceled reservations as a direct result of the Amoco Cadiz disaster." (Christian Science Monitor, 3/13/79, p. 16.)

Deficiency: A major attraction is Port Angeles harbor and the attendant recreational opportunities it offers to the tourist. Many tourists come to Port Angeles because of the salmon fishing that is available within a short distance from the launching area. During the fishing season, from April through September, it is not uncommon to see around 100 boats per day launched from the boat launching area near the gate of the Coast Guard Station and directly in the midst of the area selected by Northern Tier for their marine terminal. Although Northern Tier has indicated they would attempt to keep the boat launching area intact, there are serious questions about the feasibility and safety of having small boats mooring in and around the large tankers. Water quality as it relates to marine life and continued good fishing is also a major concern. The "Water Quality", "Fisheries" and "Oil Spill Risk Analysis" sections of this report will further discuss this concern.

② Omission: A large segment of the tourists visiting Port Angeles are in transit to Victoria, B.C. and in many cases it is their first extensive visit to a salt-water port. The City and downtown businesspeople are engaged in a large-scale improvement program to upgrade the waterfront. It is our intention to convert the downtown waterfront from industrial uses to a people place and thereby enrich the lives of our own residents as well as making tourists want to return to Port Angeles. This downtown area is directly South of the proposed marine terminal. Therefore, if steps are not taken to beautify and improve the aesthetics of the marine terminal it could ruin everything the City and the business community are attempting to accomplish. It is our desire that the analysis on the marine terminal could include steps or procedures that would improve its aesthetics. The BLM document fails to address this concern.

③ Table 2.1.1.13; Page 2-32.
Deficiency: Under the second paragraph on page 2-32, brief mention is given to "....regular ferry service to Victoria, British Columbia." This ferry service contributes to a large percentage of harbor vessel traffic (particularly in summer), yet it is not documented in Table 2.1.1.13-1.

126 CONT

④ Sec. 2.1.1.14; Page 2-37.
Question: How many persons rode those 855 round trips made by Black Ball Ferry to Victoria in 1977? 1978?

⑤ Page 3-47.
Error: Under construction phase....Clallam County does not own the public boat launch.

⑥ Sec. 7.10; Page 7-4.
Question: How will NTPL oil port decrease the recreational boating facilities, in percentage points, in a ten (10) mile radius from the center of Port Angeles harbor? In a 20 mile radius? From a 30 mile radius?

In percentage points, how much will the oil port, with attendant tankers, decrease the recreational and commercial fishing in a 10 mile radius of center of Port Angeles harbor? How much in a 20 mile radius?

⑦ Page 3-39.
Deficiency: Two boat ramp launches will be displaced at Ediz Hook.

Page 3-39; Para. 3.
Error: Two boat launches are used throughout the year at Ediz Hook.

⑧ Question: What will be the effects of the pipeline on the Port Angeles public pier and Salmon Derby Days, an annual event?

Page 3-54.
Deficiency: Does not speak to passive enjoyment of Ediz Hook by motorists driving out just to enjoy the view and watch fishing boats come in.

⑨ Sec. 3.1.15; Page 3-49
Deficiency: It is not mentioned what the actual loss of tourism dollars would be from construction and operation activities. It is also not mentioned that conditions of crowding already exist, particularly in housing/motels, during the summer months.

⑩ Sec. 1; Page 2-38.
Omission: BLM shows a picture of ONP Visitor Center on page 2-38, but gives no mention of its proximity to Port Angeles' downtown and the fact that it is located within three (3) miles of the NTPC terminal.

No mention of the National Environmental Study Area which is adjacent to the visitor center and which was used by 7500 persons in 1978. No mention of the fact that the visitor center offers a spectacular view of the Port Angeles Harbor and the proposed unloading facilities. No mention of the annual 174,386 (1978) visitors which toured the visitor center and enjoyed the surrounding picnic and viewing lawns.

Hurricane Ridge offers outstanding views to the north, as well as into the inner Olympic Mountains. The viewing area north of the Hurricane Ridge Lodge and the hiking trails around Mt. Angeles, receive heavy use by visitors for this reason. The BLM should include these points.

⑪ Page 3-37.
Omission: One of the main viewing points on the Olympic National Park road to Hurricane Ridge is nine (9) miles up from Port Angeles. A viewpoint (at the tunnels) looking north offers a panorama view of the Dungeness area and the Strait of Juan de Fuca. Green Point is clearly visible and the tank farm would be a definite visual intrusion.

⑫ Page 2-30.
Error: Elwha is misspelled Elwah. Olympic National Park acreage is now 908,692.46.

⑬ Page 2-31.
Omission and error: The map has several omissions and errors. a) Olympic National Park should be shown in the recreational category or, better yet, as a category by itself. b) The Heart o'the Hills parkway corridor and park headquarters should be shown as Park land. c) Dungeness Spit should be labeled and color-coded to reflect its status as a National Wildlife Refuge; "recreational" is not an adequate description.

⑭ Page 2-38.
Error: The correct acreage for the total Park is now 908,692.46.

⑮ Pages 3-2 and 3-4.
Deficiency: In reference to the Olympic National Park, "Main park boundary" is a meaningless term.

⑯ Page 3-47.
Deficiency: Impacts on visitors to the Olympic National Park who expect and seek a pristine environment, should be discussed in the section on Recreational Resources.

⑰ With the Hood Canal Bridge now inoperable, visitation to the Olympic National Park may decrease, but the pressure for overnight stays will likely increase as tourists find it impractical to make a day trip to the Park.

⑱ Sec. 1.5; Page 1-59.
Error: The construction of an oilport in the Port Angeles harbor will not just "interrelate with (Olympic National Park's) pure air policies," it would violate those Class I air quality standards several times a year.

⑲ Page 3-7.
Error: In the section under visibility, BLM states "the effect on visibility in the Olympic National Park would be evident only to an observer on one of the ridges...." This is an error. The Park Visitor Center located three (3) miles from the unloading facility would be affected. The view from the front lawn and front door is currently unobscured.

Sec. 3.1.2; Page 3-7.
Deficiency: The effect on visibility in Olympic National Park would be evident to more than "an observer on one of the ridges." Thousands of visitors drive up to Hurricane Ridge every month of the year, many of them primarily for the splendid views of the Strait, Canada, Port Angeles and the mountain ranges.

⑳ Page 2-46.
Error: Second paragraph understates tourism. "Thousands of tourists come to the area each year...." Olympic National Park records visitation of nearly three million.

Sec. 2.1.1.14; Page 2-38.
Deficiency: Olympic National Park was visited by nearly

CONT

⑳ three million persons in 1978. The 1977 figures given by BLM should be updated.

Vista points along the road to Hurricane Ridge also include clear views of Green Point, proposed site of the onshore storage facility. Just a few hundred yards from the Lodge parking lot on Hurricane Ridge is a breathtaking vista northward not only to the Strait of Juan de Fuca and Canada, but to Ediz Hook.

Olympic National Park has eight endemic wild flowers and the endemic Olympic marmot as well.

㉑ Sec. 2.1.1.10; Page 2-27.
Omission: Trails were omitted from the listing of cultural resources.

㉒ Sec. 2.1.1.12; Page 2-31.
Omission: Several recreational areas have not been included in this map: Striped Peak recreation area and viewpoint on Freshwater Bay; City parks in Port Angeles; the Olympic National Park Visitor Center and the portion of the Park included in the 10 (ten) mile radius from tanker berths; and, one section of the Dungeness Spit was not depicted.

㉓ Sec. 3.1.14; Page 3-48.
Question: What would be the effect on Olympic National Park wilderness beaches if a tanker collision occurred off Neah Bay? Sport fishing is an important recreational resource in the area, but so is a wilderness beach for hikers, backpackers, etc.

㉔ Page 3-50.
Error: This is a gross assumption! Santa Barbara does not have a national park in its backyard attracting millions of visitors. Damages from an oil spill would have a major impact on tourism.

㉕ Sec. 3.1.14; Page 3-48.
Omission: BLM makes no mention of the proximity of the Dungeness Spit to Port Angeles Harbor or Green Point. The spit is a major recreational area, attracting 80,000 visitors in 1978. A significant spill would have a serious impact on recreational use.

㉖ Question: There have been statements concerning security and potential sabotage. Would this mean access might be denied to Bonneville Power Administration for NTPC right-of-way? For security, this would make sense because a remote site with difficult access involving a major pipeline and a line into a major grid (blackout potential) would be inviting to vandals, saboteurs, etc. However, this would be a major recreation impact because the right-of-way has many current uses (e.g., hunting, all terrain vehicles access, etc.).

㉗ Deficiency: According to some sources of information, it is very probable that several petroleum-based industries will site in the Port Angeles area if a major oilport is developed here. What would the impact of such development be on recreation and tourism resources, particularly the harbor, the Strait and the Olympic National Park?

㉘ Page 3-54.
Deficiency: Does not speak to social unrest and problems related to loss of recreational facility usage for local residents not only in the harbor area where recreational use as stated would be inhibited (forbidden). Harbor usage provides daily recreational facilities for shift workers in the area for a few hours of recreation before reporting for work at the mills. It also does not speak to loss of recreational facilities related to campgrounds, parks and limited recreational facilities for such activities as bowling, swimming and roller skating. Easy access as part of City, allows total population use of Ediz Hook after working hours.

㉙ Sec. 2.1.1.14; Page 2-37, column 1 para 5.
Deficiency: From LaPush to Neah Bay there are numerous trails and a USNPS maintained coastal trail from LaPush to Lake Ozette. Car access is limited.

Sec. 2.1.1.14; Page 2-37, column 2 para 5.
Deficiency: Moorage should not be an indicator of boating and boat fishing pressure. The number of trailered boats far exceeds moorages. (See Sequim Bay Marina EIS for data.)

Sec. 2.1.1.14; Page 2-37.
Omission: The recreational pursuits section completely ignores whale watching and bird watching in this area. There are chartered boat trips off the coast and in Puget Sound for both.

㉚ Sec. 2.1.1.15; Page 2-39, Table 2.1.1.15-4.
Deficiency: There is updated information on recreational bottom fishing available at the University of Washington and State Department of Fisheries.

Sec. 2.1.1.15; Page 2-41, Table 2.1.1.15-7
Omission: The BLM has omitted sport fishing and general tourism in this table. These are two of the major business in Washington.

Sec. 3.1.14; Page 3-47.
Omission: The impacts section on recreation is generally insufficient. Impacts are general, have no economic evaluation, and certain types of impacts are completely omitted from the statement.

㉛ Sec. 3.1.14; Page 3-48, column 1 para 3.
Deficiency: Green Point. If impacts are transmitted to Dungeness Spit there will be very significant impacts on recreation.

㉜ Sec.5.1.7; Page 5-5.
Comment: Also, if the sediment was washed onto beaches or shellfish areas what would the impacts be? Also, strong odors would effect recreationists in the immediate area.

㉝ Sec. 7.10.1; Page 7-4.
Comment: A maintained corridor would increase public access to wildlife habitats, thus increasing pressure from general disturbance, i.e. ORV traffic, and by localizing hunting pressure.

CONT

T

## TRANSPORTATION

Local government officials have reviewed the section of the BLM-DES dealing with transportation, and have found the information to be "completely inadequate." Little definitive information exists upon which an analysis can be based. Apart from the highly-increased use from construction workers and construction equipment, a great deal will depend upon whether large pieces of equipment and material will be brought in by truck or barge. The BLM should address the matters discussed below.

In the Port Angeles area, a primary concern is the existing roadway extending along Ediz Hook, which is presently in a condition of deterioration. A part of the lease agreement the city has with the Coast Guard requires us to provide a paved road on the Hook to the Coast Guard base. While the road is still passable, it is in definite need of rebuilding from the sub-base up. Tentative plans call for the city to rebuild this road after the Ediz Hook Beach Erosion Project is complete, which is anticipated during the summer of 1979. Proposed plans for the roadway call for a 22-foot width and designed to support highway (H-20) loading.

① The city faces a dilemma in that we need to rebuild the road in 1979 to maintain our agreement with the Coast Guard, but if the reconstructed road is not heavy enough to accommodate the passage of equipment to construct the marine terminal, it would be a waste of funds. What is needed from Northern Tier is then a forecast of traffic type and volume to see if a 22-foot, H-20 roadway is adequate. Secondly, if this type of road is not adequate, would Northern Tier contribute to a heavier roadway?

In addition, the overall impact of bringing an additional 500 or more families must be analyzed for its impact on the street system of Port Angeles. The city has been working gradually to upgrade our street and traffic system but this intensified use in such a short period of time would simply overwhelm the present traffic system.

② Deficiency: NTPC Washington State application does not refer to the Port Angeles area-wide TOPICS study conducted by Harstad & Associated in 1973, which deals with area traffic problems and possible solutions. BLM-DES does refer to this study, but goes on to cite a 1.5% per annum traffic growth rate used in the NTPC application rather than use the 5.3% per annum traffic growth rate which Harstad established by actual traffic counts and studies in the area.

Neither NTPC or BLM conducted any traffic studies in the Port Angeles area. Such studies are a necessary part of an impact analysis.

③ The transportation sections, including impacts and mitigations, contained within the BLM-DES seem to be based greatly on Northern Tier's Washington State application or information which is as much in doubt as is some of that which NTPC based their conclusion on.

Since BLM-DES contains similar information as the NTPC Washington State application, many of the same questions are raised and omissions are present.

④ Information from the applicant discussing equipment at the storage facility has been inadequate. The estimated number of dump trucks is four. Apparently, this is just on site dump trucks as they also show two front end loaders, and two front end loaders will keep far more than four dump trucks going. The only assumption can be made is that they are going to use an awful lot of local contractor's trucks to haul their gravel for their tank farm, and this figure is not shown on their estimated daily traffic.

In material of public record, the NTPC refers to the major highway and railroad crossings as normally being bored and cased with steel pipe. They list only two crossings in Clallam County which are the Milwaukee Railroad and U.S. 101 as applying to where the bored and steel pipe goes. We have many roads in Clallam County which we feel are major. Also, all our minor roads we feel should definitely be protected with casings under the right of way.

⑤ The information on access to the tank form is inadequate. In public records, NTPC refers to a new route from U.S. 101 to the storage facility, but the only route shown any place or referred to is just a new road from our existing county Old Olympic Highway into the storage facility. The location of their proposed road is on a very blind portion of the Old Olympic Highway, and the amount of traffic going in this way will definitely require some kind of acceleration and deceleration lane. This area is also subject to severe icing conditions in the winter, and it has a fast load of traffic through this area. It would be irresponsible not to give special attention to this situation for the operation of traffic, to say nothing of the much longer traffic count during the construction period. The existing Old Olympic Highway will have to be widened out as there are no shoulders on it. Also, this project should have proper signing and striping. What about during the construction? Any furnishing of signing and traffic control for the county road system and the state highway system? This is going to be a complete burden to the citizens of Clallam County and definitely should be worked out before any permit is ever issued.

Section 1: Page 1.18
Comment: The Old Olympic Highway is not a lightly traveled road for the level of service the local people are accustomed too. In 1978, it was having 2530 cars a day. It also is used as a bypass for State Highway 101. No provissions have been made to widen or upgrade this road.

⑥ NTPC information of public record indicated peak volumes during construction, well below the capacity for virtually every road for which capacities were calculated. This is very hard to believe where a lot of the roads we have are 16 to 18 feet wide, and there is no way you can increase the volume on them without widening the roads.

Neither BLM nor NTPC has addressed the level of service when they were talking about peak volume capacities. There are all kinds of levels of service with an inconvenience factor. We do have a tolerable level of service on most of our roads at the present time, and they are going to use the level of capacities which will put the level of service way below what we are normally used to.

CONT

In some cases NTPC has projections of traffic on some of the local road networks up to 1,040 trips per day, which is completely intolerable. NTPC has stated that to the extent possible, existing public and private roadways will be used for access to the pipeline construction right of way. There are many user's rights roads that are not on the county system that actually the hunters and loggers use, which are completely inadequate to handle heavy pipeline type construction. Some protection must be built in to assure that these roads, if they use them, will be built up and maintained to a level that will not interfere with the local residents after they get done with the pipeline construction.

Deficiency: Applicant has not listed the access routes for moving heavy materials and equipment to the pipeline area.

Deficiency: Did not show any standards to be used in improving existing transportation facilities.

Deficiency: Applicant has not described procedures to minimize erosion and other adverse consequences during the removal of vegetation, excavation of borrow pits, etc.

Deficiency: How does NTPC plan on holding down dust on haul roads?

Page 8-36
Deficiency: The road from State Highway 112 to Freshwater Bay needs complete re-building if site is located there.

Figure 1-4-12; Page 1-45
Deficiency: Proposal shows they will need roughly 66.4 cubic yards per 100 foot station for the bedding and select backfill around the pipes. Where is the material coming from? How is it going to be hauled?

Table 3-1.13-1; Page 3-45
Error: The increased traffic on Old Olympic Highway will be a significant impact. Also, the intersection with 101 will be a real problem during construction phase. How does the developer plan to control traffic at these and other locations of traffic congestion?

Page 4-7 & 5-21
Question: A road management plan is to be submitted. Such a plan should include road limits (road closure criteria) Most of the roads going south from 101 to area of pipeline would have to have road limits as they do not have any base and all are too narrow.

Page 3-108
Deficiency: Many of the roads leading to the pipeline spread have current volumes of around 100 cars per day. When you add 440 to 480 workers using these roads also, it will create safety problems on thes roads. The applicant says maximum traffic might reach 1000 vehicle trips per day.

⑦ Omission: The BLM-DES fails to address the problem of increased costs for construction materials and labor due to increased demand and short supply of gravel, concrete, steel, trucking, skilled personnel, etc.

⑧ Figure 1.4-12: Page 1-19
Error: For select fill on the onshore storage facilities, they show 35,000 cubic yard of select fill. The County Road Department computes it to be closer to 780,000 cubic yards. Where will it come from? How will it be hauled? Also, they show no select fill for the pipeline, but figure 1.4-12 shows select fill around the pipe.

⑨ Omission: No place do they bring up the increased help needed by the County Road Department to handle extra maintenance complaint calls from local people, added engineering, etc.

NTPC information, which is a matter of public record, discusses a stock pile area at Discovery Bay. With the recent amendment to the NTPC proposal regarding the "Cross-Sound" pipeline route, will the stock pile area be relocated near Sequim or Port Angeles? At what specific location? What impacts will occur as a result of this relocation?

⑩ Page 2-156
Deficiency: The negative thrust of the statement related railroad services should be eliminated and properly definitive statement included.

⑪ Page 2-156, Par. 1
Deficiency: Reference is made to U.S. 101 and figure 2.1.1.13-1 (page 2-13) Figure 2.1.1.13-1 does not depict the fact being verbalized.

⑫ Deficiency: Crossing roads will involve traffic stoppages and slowdowns, representing another inconvenience to the public. Please give details on traffic interference and add a reasonable dollar value for this as part of the public costs in the cost-benefit evaluation of the project.

⑬ Deficiency: 2.1.2.13: Transportation and Utility Networks: What provision will be made for summer traffic along Hood Canal during construction? This is of recently increased urgency since the sinking of the Hood Canal Floating Bridge. The area is closed at times for hours by landslides and those landslides may well be increased when NTPC tries to place pipe trenches just above the slide-sensitive hill! What effect will construction have on slope stability both here and elsewhere along the pipeline? The impact statement should address these concerns.

Sec. 5.1.11: Page 5-8
Question: How can #1 Paragraph 1 & 2 be considered significant adverse impacts if applicant has not adequately addressed them and neglected to propose positive mitigating measures?

Paragraph 1, 2, 3. Col. 1
Deficiency: What is source data for ERT's traffic volume statistic estimates?

Question: How many of truck deliveries will exceed load weight restrictions and by how much?

⑭ Deficiency: Does not speak to Front Street adequately related to traffic volumes and problems. This is main access route for Port Angeles, and through traffic west on Highway 101.

Deficiency: Does not include ADDED LOG truck traffic created by forced removal of Crown Zellerbach and ITT Rayonier log storage from harbor to land.

Deficiency: Does not speak to traffic congestion in total relating to rerouting of traffic from west seeking city access. In many cases, destinations of this traffic would

126 CONT

need to use Front Street at some point.

Deficiency: Does not speak to traffic congestion at city intersections and traffic lights.

Paragraph 4.
Deficiency: All traffic increases regardless of source would have significant impact on city traffic flow.

Column 3
Deficiency: Other abandonment sections have not established abandonment removal procedures.

Paragraph 1: Page 3-43
Deficiency: Northern Tier assumes use of railroad for deliveries. What is site destination of rail deliveries? Will trucks and/or barges be necessary for completion of deliveries and if so in what number? If rail delivery not possible, how many truck or barge trip deliveries will be needed to replace this anticipated method of delivery?

⑮ Deficiency: Might possibly is not adequate site specification for relocation VOR station.

Deficiency: Does not establish availability or advisability of moving VOR to PA airport. Is land with 750 foot clearance in all directions available there?

Deficiency: Who would pay for engineering studies, revision of all navigation charts and relocation of VOR? How long a period of time is required for relocation? Are there any air navigation safety hazards to ongoing air traffic involved? What are procedural requirements and agency responsible for same?

What provisions have been made to regulate traffic during construction at the various construction sites?

What provisions have been made to provide parking, material stockpiling and equipment staging for the tanker facility, tank farm and pipeline route?

What are the proposed haul routes for materials to be delivered by land and also haul routes from barge deliveries to various construction sites?

Are there any provisions being made for mass transit movement of manpower both during construction and operation?

Where are the locations of gravel pits and justification of amounts from each?

What standards will the haul roads be rebuilt to.

What method does NTPC propose to use to keep maintenance up on all haul roads?

Where are plans for traffic control for dangerous intersections?

Proposed staff to handle complaints from increased traffic and dusty conditions should be planned for.

## UTILITIES

U

① Several of the comments relating to "utilities" are included in other relevant sections of this report, such as "Energy" and "Water Quality".

Section 1-14; Page 1.14-15.
Omission: Identify all wastewater sources and estimate the quantity and quality of discharge from each source.

Omission: Estimate quantities of storm water runoff, with substantiating data sources.

Omission: Provide a detailed description of handling and treatment of oily waste stream, including the expected stream effluent quality from the treatment equipment.

Omission: Describe disposal methods for in-plant oil streams from the pipeline facilities such as scraper traps, strainers, oil water separators, and sumps.

Omission: Estimate the quantities of sanitary and other waste that will require handling or treatment by others.

Omission: Substantiate the suitability of septic tanks at the proposed locations.

Omission: Identify quantities, location, and treatment methods required for discharge of the pipeline hydrotest water.

Omission: Identify and summarize provisions of applicable comprehensive solid waste plans and state hazardous waste regulations.

Omission: Identify types, sources, and estimated quantities of solid waste from construction activities or operations.

② Page 3-37.
Omission: Describe the proposed disposition of solid waste as required by local, state and federal regulations.

Comment: Impermeable membranes should be placed under and over oily sediments disposed on-site to prevent leaching to groundwater; this should be specified. NTPC makes the assumption that disposal in an approved sanitary landfill is adequate. Local governments will need assistance to adequately protect groundwater. If there ever is a major spill few sites would be able to handle oily cleanup wastes without great risk of future groundwater contamination. The BLM should address this concern in depth.

③ Question: What effect will the project have on the amount and type of solid waste produced in the community?

Question: What effect will any induced growth from secondary petroleum-related growth have on the amount and type of solid waste produced?

Question: Are disposal areas available and adequate?

④ Question: Will the project use, or encourage the development of, recycling or other efficient methods of handling wastes?

CONT.

Section 4.

⑤ Deficiency: The Clallam County Public Utility District will not supply water to test the transmission line; and therefore, Northern Tier must find an approved alternate source and also means of disposing of the contaminated test water. The BLM should address these concerns.

⑥ Question: Page 1-56, Paragraph 10 What disposition will be made of the soil saturated with crude? How will it be treated? Where will it be disposed of?

Question: What disposition will be made of other oily wastes in the case of an oil spill? Can such materials be burned without violation of the clean air act?

Deficiency: Page 1-47, column 1, paragraph 4. This paragraph does not discuss what will happen to the debris, slag and contaminants removed from the pipeline.

⑦ Deficiency: Basic questions remain unanswered regarding the production, accumulation and disposal of solid waste at both the on-shore and off-loading facility.

These questions are:

1. What amount and type of solid waste will be generated?
2. Will industrial or hazardous material be generated at either the tanker facility or the tank farm?
3. Will special or separate disposal methods be required at the Port Angeles landfill?
4. ⑧ What impacts on the domestic water system, sanitary sewer system and solid waste collection and disposal system will the increased population during construction and after have?
5. ⑨ What method will be used to dispose of bilge waste and bilge water (ballast)?
6. ⑩ Impermeable membranes should be placed under and over oily sediments disposed on-site to prevent leaching to groundwater; this should be specified. NTPC makes the assumption that disposal in an approved sanitary landfill is adequate. Most sites throughout the state do not adequately protect groundwater. If there ever is a major spill, few sites would be able to handle oily cleanup wastes without great risk of future groundwater contamination.
7. What method of disposal will be used for the oily materials which will routinely result from continuous cleanup of oil spillage (i.e. absorption material, oil soaked booms, etc.)?
8. ⑪ The amount of residue resulting from tank water drawoff operations and tank bottom sediment removal should be presented in order to ascertain whether there is adequate capacity in proposed waste disposal sites to handle the volume. It also should be demonstrated that the ground surface within the diked areas is impervious to oil seepage in order to assure protection of local groundwater. If these areas are not impervious to oil residues, the means by which groundwater resources will be protected should b identified.

⑫ Deficiency: The existing water uses of the Ediz Hook water main should be defined to enable assessment of its capacity to serve the unloading facility. The existing system may not have the carrying capacity to meet peak loads imposed on the system by tanker demands and still serve the City of Port Angeles. Also, information about water need and timing of withdrawal should be provided. Additional information on sufficiency of water supplies for firefighting should be provided if domestic water is in any way intended to be used for firefighting.

Deficiency: Additional information is needed to answer the following basic questions:

1. ⑬ Are there any fresh water requirements for fire protection?
2. What will be the maximum rate of use of potable water for (a.) ballasting (b) domestic and similar uses (c.)miscellaneous uses at port facility and support facilities?
3. What present requirements are necessary at the off-loading facilities?
4. What provisions are planned to prevent contamination of the City's potable water system?
5. What provisions have been made to supply the tanker facility with potable water in the event the City service is interrupted?
6. ⑭ What amount of water will be needed for hydrostatic testing of the pipeline and where will this water be discharged?
7. The applicant should detail the location (river mile and placement) and type of water intakes, including aquifers to be used, if any, and describe the impact of withdrawals on water volume, aquatic biota, and downstream users.
8. ⑮ What impacts on the domestic water system, sanitary sewer system and solid waste collection and disposal system will the increased population during construction have?

⑯ Comment: The subject of sanitary sewage and wastewater treatment is inadequately addressed by the BLM-DES. Additional information is needed and some of the questions which must be addressed are:

1. What method will be used to dispose of sanitary sewerage? What quantity of sewerage will be produced?
2. If a holding tank is used for sanitary sewerage, what will be the source of the sewerage? (i.e. tanker ships, shore facilities, etc.?)
3. Will sewerage from tankers be off-loaded at Port Angeles? If yes, what will be the chemical content in the sewerage?
4. What provisions are being made to handle storm water drainage and treatment at the tanker facility?
5. What method will be used to dispose of bilge waste and bilge water (ballast)?
6. The applicant should propose a treatment process and methodology to treat the hydrostatic test water if bactericides are used.

CONT.

7 In the NPDES application, the applicant states that contaminants other than oil, grease, and chlorides are not expected to be produced by the operation of the marine terminal. However, substances such as phenols, sulphur, and nitrogen-containing compounds, which are water soluble, can enter solution when oil comes in contact with water. These are considered potential constituents of the effluent and should be identified as such in item 16.

8. Also in the NPDES application the applicant states that insufficient information is available to estimate the concentrations of the parameters in influent and effluent water. Information from other similar facilities should be reviewed and estimates made for all specified parameters.

9. The applicant states in item 7 of the NPDES application that discharge receiving water will be the Strait of Juan de Fuca. It is stated that the holding basin from Phase II will discharge effluent to Siebert Creek. If so, this future discharge receiving water should be identified in the application.

10. Provisions for the discharge of water used to hydrostatically test the pipeline and storage tanks must be included in the NPDES permit in order to satisfy the requirements of WAC 463-42-455.

## WATER QUALITY

V

① Deficiency: The assumption that groundwater quality will be sufficiently protected by density separation between oil and water may not be valid. Once the oil reaches a groundwater supply point, replacing that supply or treating the water would be required. The water supplies downstream of the pipeline may lie in high permeable river gravels and pipeline crosses. If so, in several locations short distance separation will not provide much protection. Groundwater monitoring wells between the pipeline and the supply well would allow observations and time for corrective action.

Ponds or oil residue disposal fills on site should be lined to prevent contamination of the groundwater; if such provisions are contemplated, they should be described.

Surface areas within the diked areas must be impervious to oil seepage in order to assure protection of local groundwater. If these areas are not impervious to oil residues, the means by which groundwater resources will be protected should be identified.

② In order to assess the potential oil leakage from the submerged pipeline, estimates should be provided for the maximum amount of oil that could escape, even with the leakage detection system working and activated. At maximum operating conditions, the leakage rate not detected by the leakage detection system shouldbe 500 barrels per hour (100,000 x 0.5% = 500).

③ The applicant should provide specific information regarding the burial depth of underwater pipelines so that the potential anchor damage can be accurately assessed. Also, by providing burial depths, estimates of dredge quantities can be prepared.

Section 1-41; Page 1-41.
Deficiency: Paragraph beginning: ". . . the original site drainage patterns . . ." Much additional surface water will be produced because of the metal and other hard surface that will cover much of the area. Allowed to go into the ground it could well "grease" the clay layer of the bluff and cause massive bluff slippage. Very careful and complete handling of this extra surface water needs to be planned so that it passes safely into the strait.

④ Section 1.4.
Deficiency: Parking lot construction, roads and other structures should be described relative to amount of silt during construction and stormwater carried silt, road oils, toxic materials as benzalpha-pyrenes, heavy metals and coliforms, giving quantity of each and final deposit of such materials in the environment. What disposal will be made of effluent from laboratory sinks? What toxic materials other than oil will be discharged from this source?

⑤ Section 1.4; Page 1-13-14.
Paragraph 10 states ". . .affluent would be discharged into Siebert Creek and the Strait . . ." However discharge for Siebert Creek is not shown on figure 1.4-3, Page 1-13.

⑥ Section 1.4; Page 1-14; column 2; paragraph 3.
There is no discussion of water purification before discharge. BLM implies that the only thing in the water will be oil, yet in the risk analysis and impact sections they discuss soluble factions. BLM should identify the soluble factions in this water and how they are to be removed.

⑦ Section 1.4; Page 2-13.
Deficiency: Biological components: The impacts on Siebert Creek are directly connected to the onshore storage facilities and should be addressed under this heading. By separating the two the impacts are not as clear as they should be to the reviewer.

⑧ Page 3-14; column 1; paragraph 1.
